THE STANDARD CYCLOPEDIA *of* HORTICULTURE

L. H. BAILEY

The Standard Cyclopedia of Horticulture

Edited by L. H. BAILEY
Author of "Hortus Second" (*with* ETHEL ZOE BAILEY)

IN THREE VOLUMES

Here is the one final authority used by thousands of flower-lovers everywhere. This set is universally recognized as the most complete and authoritative reference work on horticulture available. It contains detailed discussions of more than 40,000 plants, and Dr. Bailey has had the assistance of more than 500 collaborators—each a specialist in his field. It gives every answer in simple, convenient reference form. The original edition was in six volumes but was reissued in three volumes. The book contains more than 3,000 illustrations, including 24 color plates.

When this "Cyclopedia" was published the following press comments were received:

"The Bible and Britannica of garden-folk, amateur and professional alike."—*The Nation.*

"If we could have only one book on gardening—this would be the one."—HORTICULTURAL SOCIETY OF NEW YORK.

"An indispensable work of reference to anyone who is interested in the land and its products."—*Boston Transcript.*

"It is no exaggeration to state that Bailey's new work is the best cyclopedia obtainable for all who are concerned, either remotely or intimately, as amateurs or professionals, with horticultural pursuits."—*The Florist's Review.*

XL. Formal gardening, with veronica and phlox in the foreground

THE STANDARD CYCLOPEDIA OF HORTICULTURE

A DISCUSSION, FOR THE AMATEUR, AND THE PROFESSIONAL AND COMMERCIAL GROWER, OF THE KINDS, CHARACTERISTICS AND METHODS OF CULTIVATION OF THE SPECIES OF PLANTS GROWN IN THE REGIONS OF THE UNITED STATES AND CANADA FOR ORNAMENT, FOR FANCY, FOR FRUIT AND FOR VEGETABLES; WITH KEYS TO THE NATURAL FAMILIES AND GENERA, DESCRIPTIONS OF THE HORTICULTURAL CAPABILITIES OF THE STATES AND PROVINCES AND DEPENDENT ISLANDS, AND SKETCHES OF EMINENT HORTICULTURISTS

BY
L. H. BAILEY

Illustrated with Colored Plates, Four Thousand Engravings in the Text, and Ninety-six Full-page Cuts

XL. Formal gardening, with veronica and phlox in the foreground (in color) *Frontispiece*

XLI. A good fern in southern California.—*Alsophila australis* 1217

XLII. A young Celeste fig tree, as grown in Georgia 1234

XLIII. Floriculture.—A house of begonias, with a row of ferns 1242

XLIV. Forcing of grapes.—Muscat of Alexandria 1263

XLV. Ferns in a public garden, with springtime bloom (in color) 1307

XLVI. Type of an old-time formal garden.—Washington's garden at Mt. Vernon . 1315

XLVII. Fringed gentian. *Gentiana crinita* 1327

XLVIII. The garden gladiolus, variety "Peace" (in color) 1343

XLIX. The Niagara grape (in color) 1380

L. The grapefruit. About one-third natural size 1391

LI. A home greenhouse 1410

LII. Heliotrope, an old-time favorite 1452

LIII. Good use of spring flowers.—*Mertensia virginica* 1470

LIV. Herbs and shrubs employed about a pond 1481

LV. Hollyhock 1497

LVI. Roman hyacinth.—One of the forms of *Hyacinthus orientalis* 1614

LVII. A night-blooming cactus.—*Hylocereus tricostatus* in Hawaii. Hedge planted by Sibyl Moseley Bingham between 1831 and 1840 1625

LVIII. One of the many beautiful garden irises.—Probably one of the hybrid or derivative forms of the germanica group 1657

LIX. Japanese irises.—*Iris lævigata* 1675

LX. The black walnut.—*Juglans nigra* 1717

LXI. Landscape in southern California.—Bougainvillea, Banksian rose, *Phœnix canariensis* (in color) 1761

LXII. Example of the large rural park. View in Prospect Park, Brooklyn . . 1781

LXIII. View in a landscape cemetery 1812

LXIV. A good field of lettuce 1846

LXV. *Lilium speciosum* in an attractive setting (in color) 1866

LXVI. The tulip tree.—*Liriodendron Tulipifera* 1891

LXVII. *Magnolia Soulangeana*, the commonest hybrid magnolia in the North . . 1965

LXVIII. A Paheri mango tree in fruit.—Florida 1989

Facing page
LXIX. Muskmelon of the Hackensack type (in color) 2026
LXX. *Narcissus poeticus.*—The poet's narcissus; hardy and good 2108
LXXI. North American horticulture.—A commercial cabbage field in New Jersey . 2169
LXXII. North American horticulture.—A peach orchard in eastern Maryland . 2211
LXXIII. North American horticulture.—An orange grove in Florida . . . 2230
LXXIV. North American horticulture.—Foothill orchards in California . . . 2284
LXXV. Nut-culture.—The original (native) tree of the Butterick pecan, in Illinois; a commercial pecan plantation in Georgia 2296
LXXVI. *Odontoglossum crispum,* with *Asparagus Sprengeri* decoration . . . 2320
LXXVII. Onion.—The Prizetaker, a handsome pale yellow popular variety . . 2347
LXXVIII. A cluster of oranges, the Pineapple variety (in color) 2369
LXXIX. An orchid fancier's house.—Cypripediums, Selenipediums, Miltonias, Lælias, Oncidiums 2379
LXXX. *Osmunda cinnamomea,* the cinnamon fern, in its native place . . . 2414

F

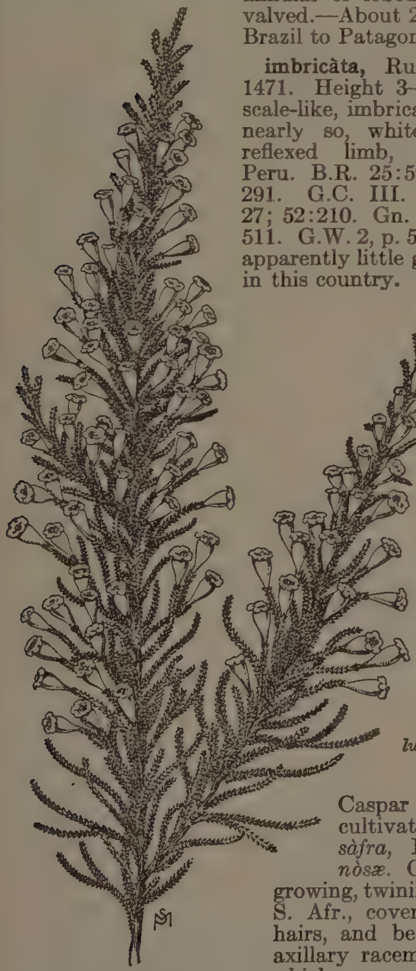
FÀBA (*phago*, to eat; yields edible seeds). *Leguminòsæ.* A genus established by Tournefort for certain plants now referred to Vicia. *Faba vulgaris*, Moench, is the horse bean, broad bean or Windsor bean, now accepted as *Vicia Faba.* From other groups in Vicia, it differs mostly in its stiff erect habit and the very large fleshy seeds and pods. The name *Fabaceæ* is sometimes used instead of *Leguminosæ*, and sometimes for the papilionaceous leguminosæ.

FABIÀNA (after Francisco Fabiano, Spanish botanist, Valencia). *Solanàceæ.* Small heath-like shrubs; one is sometimes grown in cool greenhouses and in mild climates for its bloom.

Erect and branching plants, sometimes viscid: lvs. small and crowded: fls. usually many, terminal or opposite the lvs., small; corolla long-tubular, dilated or ventricose above, often contracted at the throat; stamens 5, attached on the corolla-tube; disk fleshy, annular or lobed: caps. oblong, 2-valved.—About 20 species, Bolivia, Brazil to Patagonia.

imbricàta, Ruiz & Pav. Fig. 1471. Height 3–8 ft.: lvs. ovate, scale-like, imbricated: fls. sessile or nearly so, white, with a short reflexed limb, borne profusely. Peru. B.R. 25:59. R.H. 1903, p. 291. G.C. III. 32: suppl. Sept. 27; 52:210. Gn. 60, p. 430; 72, p. 511. G.W. 2, p. 511.—This plant is apparently little grown under glass in this country. It is a rather common shrub in S. Calif., where it blooms at different seasons. In England, it is said to thrive best near the sea. Good bushes produce a wealth of well-lasting bloom in late spring. It prop. without difficulty from potted cuttings in Aug.

L. H. B.



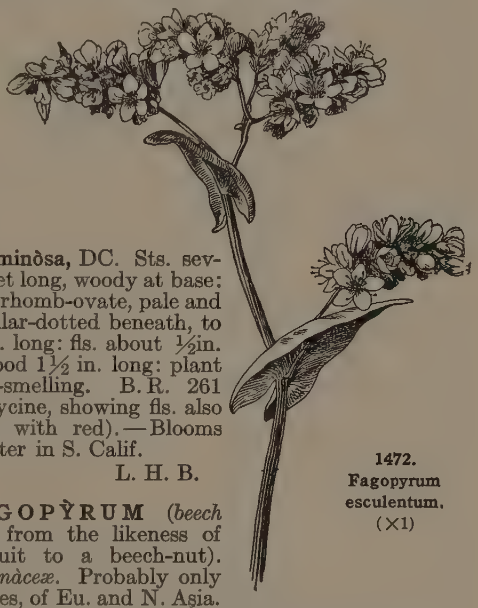
1471. Fabiana imbricata. (×½)

FAGÀRA: *Xanthoxylum.*

FAGÈLIA (after Caspar Fagelius, plant cultivator). Syn. *Bolusàfra*, Kuntze. *Leguminòsæ.* One species, a fast-growing, twining sub-shrub from S. Afr., covered with clammy hairs, and bearing all summer axillary racemes of pea-like fls. which are yellow, the keel tipped violet; standard reflexed; keel obtuse, exceeding the wings; stamens diadelphous: pod about 6-seeded, turgid. Cult. outdoors in S. Calif. and abroad under glass. The plant is allied to Cajanus, but its seeds are strophioled, pod swollen, not flattened, and the 2 upper calyx-lobes nearly distinct. The Fagelia of Schwenke (1774) is Calceolaria.

bituminòsa, DC. Sts. several feet long, woody at base: lfts. 3, rhomb-ovate, pale and glandular-dotted beneath, to 1½ in. long: fls. about ½in. long: pod 1½ in. long: plant strong-smelling. B.R. 261 (as Glycine, showing fls. also veined with red).—Blooms in winter in S. Calif.

L. H. B.



1472. Fagopyrum esculentum. (×1)

FAGOPỲRUM (*beech wheat*, from the likeness of the fruit to a beech-nut). *Polygonàceæ.* Probably only 2 species, of Eu. and N. Asia. Quick-growing annuals, with alternate deltoid or hastate lvs., small whitish fls. in racemes or panicles, 5-parted calyx, 8 stamens, 1-loculed ovary ripening into a floury 3-angled achene.—Both species are grown for the grain, from which flour is made; and in horticulture sometimes used as a catch-crop or green-crop in orchards and elsewhere for the good effect on the land.

esculéntum, Moench (*Polýgonum Fagopýrum*, Linn.). BUCKWHEAT (which see). Fig. 1472. Lvs. large and broad, long-petioled: fls. white, fragrant, in panicled or corymbose racemes: achene or grain with regular angles.

tatáricum, Gaertn. (*Polýgonum tatáricum*, Linn.). INDIA-WHEAT. DUCKWHEAT. Fig. 1473. More slender: lvs. smaller and hastate or arrow-shaped, shorter-petioled: fls. greenish or yellowish, in small mostly simple racemes from the lf.-axils: achene with wavy or notched angles, smaller than in buckwheat.—Useful in short-season climates and on poorer lands. The Fig. 1473 is made from Linnæus' original specimens of his *Polygonum tataricum*, now deposited in the Linnæan herbarium, London.

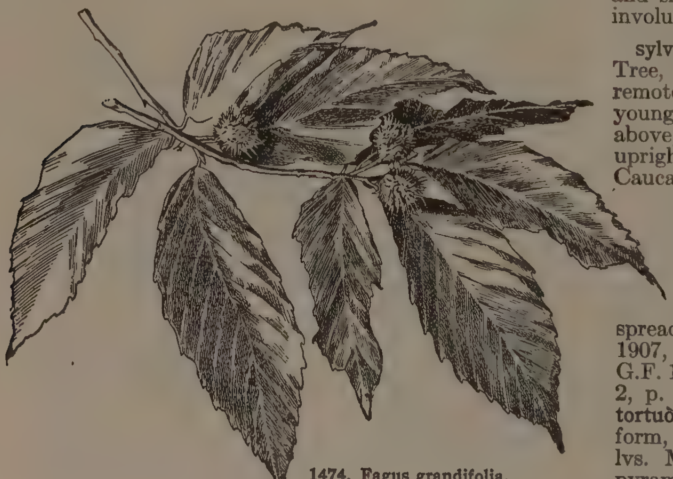
L. H. B.

FÀGUS (ancient Latin name). *Fagàceæ.* BEECH. Ornamental trees, chiefly grown for their handsome foliage, good habit and the conspicuous color of the bark; also valuable timber trees. There are marked horticultural forms.

Deciduous: winter-buds conspicuous, elongated, acute: lvs. alternate, distichous, dentate or nearly entire, with caducous small stipules: fls. monœcious, with the lvs.; staminate in slender-peduncled pendulous heads, appearing at the base of the young shoots; perianth 5–7-lobed; stamens 8–13; pistillate with 3 styles, usually 2 in an axillary peduncled involucre: fr. a brown, ovate, triangled nut, 1 or 2 in a prickly, dehiscent involucre.—Eight species occur in the cooler regions of the northern hemisphere. The species of the southern hemisphere, often included under Fagus (as *F. betuloides* and others), form the genus Nothofagus, which see.

The beeches are tall deciduous hardy trees, of noble, symmetrical habit, with smooth light gray bark and clean dark green foliage, which is rarely attacked by insects or fungi. They are among the most ornamental and beautiful trees for park planting, and attractive at every season, especially in spring, with the young foliage of a tender delicate green, and the graceful, drooping heads of the staminate flowers. All of the eight species known, save one, are in cultivation and differ comparatively little from each other. The American and the European species are especially much alike, but the first has the bark of a lighter color, the head is broader and more roundish, and the leaves less shining, turning clear yellow in fall, while the latter has a more ovate head and shining foliage, which turns reddish brown in fall and remains on the branches almost through the whole winter. It is sometimes used for tall hedges. In Europe, the beech is a very important forest tree, and the hard and very close-grained wood is largely used in the manufacture of different articles and for fuel; but it is not very durable in the soil. The sweet nuts are edible, and in Europe an oil is pressed from them, used for cooking and other purposes.

1473. Fagopyrum tataricum.

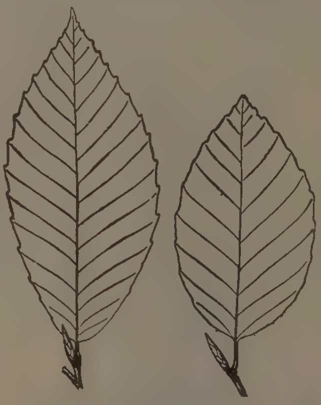


1474. Fagus grandifolia. (×⅓)

The beech prefers dryish situations, and grows best in sandy loam and in limestone soil. Propagated by seeds sown in fall where there is no danger of their being eaten by mice, or dried after gathering and kept mixed with dry sand until spring. The young plants should be transplanted every second or third year; otherwise they make long tap-roots, and cannot always be transplanted successfully. The varieties are grafted on seedling stock, usually in the greenhouse in early spring; grafting in the open usually gives not very satisfactory results.

Both in Europe and the eastern United States the beech forms extensive forests. It is today the common hardwood tree of central Europe, particularly in Denmark and Germany, raised as pure growth or mixture. It requires a loamy, preferably calcareous soil, shuns poor sand and swamp, ascends to 3,500 feet in the Alps; prefers north and east exposures, endures much shade, protects and improves the soil, and produces large amounts of wood to the acre. The wood is heavy (specific gravity 0.65 to 0.75) hard, straight-grained, of close texture, not durable. Beech is not used as building lumber, but is extensively used for ordinary wooden ware, furniture, wheelwright and cooperage stock. (F. Roth.)

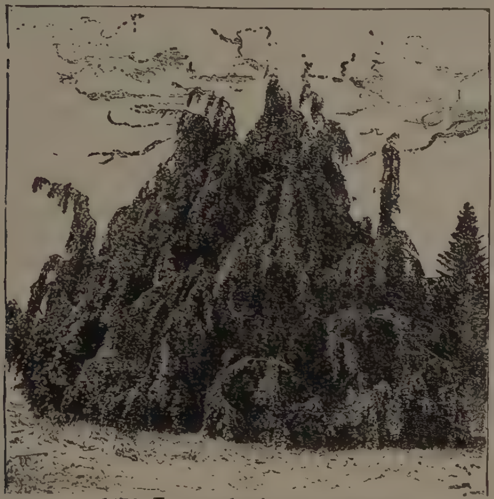
grandifòlia, Ehrh. (*F. ferrugínea*, Ait. *F. americàna*, Sweet. *F. atropunícea*, Sudw.). AMERICAN BEECH. Figs. 1474, 1475. Tree, to 80 ft., rarely 120 ft.: lvs. ovate-oblong, acuminate, coarsely serrate, silky beneath when young, with 9–14 pairs of veins, dark bluish green above, light yellowish green beneath, 2½–5 in. long: involucre covered with slender, straight or recurved prickles, ¾in. high. E. N. Amer., west to Wis. and Texas. S.S. 9:444. Em. 182. G.F. 8:125. A.G. 12:711. F.E. 20:586. Var. **pubéscens,** Fern. & Rehd. Lvs. soft-pubescent below, sometimes only slightly so. Var. **caroliniàna,** Fern. & Rehd. (*F. ferrugínea* var. *caroliniàna*, Loud. *F. rotundifòlia*, Raf.). Lvs. broader, of firmer texture, darker above: involucre rufous-tomentose, with fewer and shorter prickles: nut smaller, not exceeding the involucre. From N. J. and S. Ill. to Fla. and Texas.



1475. Fagus grandifolia (left), and F. sylvatica. (×⅓)

sylvática, Linn. EUROPEAN BEECH. Fig. 1475. Tree, to 80 ft., or rarely 100 ft.: lvs. ovate or elliptic, remotely denticulate, silky beneath and ciliate when young, with 5–9 pairs of veins, dark green and glossy above, pale beneath, 2–4 in. long: involucre with mostly upright prickles, about 1 in. high. Cent. and S. Eu. to Caucasus. M.D.G. 1902:579–582. H.W. 2:20, pp. 42, 43. F.E. 33:615. Fig. 1475 contrasts the lvs. of the American and European species. A great number of varieties are in cult., of which the following are the most remarkable: Var. **péndula,** Lodd. Fig. 1476. With long, pendulous branches, the larger limbs mostly horizontally spreading. G.C. III. 51:114. G.W. 15, p. 662. B.H. 1907, p. 393. Gn. 42, p. 65; 55, p. 267; 64, p. 167. G.F. 1:32 (adapted in Fig. 1476). Gng. 6:258. G.W. 2, p. 15; 9, p. 510; 15, p. 663. G.M. 52:807. Var. **tortuòsa,** Dipp. (var. *suenteliénsis*, Hort.). Dwarf form, with twisted and contorted branches and small lvs. M.D.G. 1912:110. Var. **pyramidàlis,** Kirchn. Of pyramidal habit. Var. **purpùrea,** Ait. (var. *atropurpùrea*, Hort.). Fig. 1477. Lvs. purple. M.D.G. 1901:

163; 1908:499. G.C. III. 24:305. F.E. 13:472; 14: 874. A.G. 18:837. G.W. 2, p. 539. A form with very dark purple lvs. and of compact habit is var. **Ríversii,** Hort. There are other forms, differing in the shade of purple, as var. *cuprèa,* Hort., and also some with rosy pink variegated lvs. Var. **purpùrea péndula,** Hort., has purple lvs. and pendulous branches, but is of slow growth. Var. **Zlàtia,** Spaeth, has yellow foliage. Var. **heterophýlla,** Loud. (var. *asplenifòlia,* Lodd.). Lvs. deeply cut, often almost to the midrib, into narrow lobes. A very graceful variety, forming a dense and low, shrubby tree. Mn. 1, p. 61. F.E. 18:314. P.G. 3:163. Less important varieties, but sometimes grown, are the following: Var. **cristàta,** Lodd., with deeply toothed, curled, small and clustered lvs.: of slow growth. Var. **incìsa,** Hort. Similar to var. *heterophylla,* but lvs. less deeply cut. Var. **macrophýlla,** Hort. Lvs. large, to 5 in. long. Var. **quercifòlia,** Schelle (var. *quercoìdes,* Hort.). With deeply toothed and sinuate, rather narrow lvs. Var. **quercoìdes,** Pers., often confused with var. *quercifolia,* is a form with dark and rough, oak-like bark. M.D.G. 1909:509.



1476. Fagus sylvatica var. pendula.

F. asiática, Winkl.=F. orientalis.—*F. Engleriàna,* Seemen. Tree, about 50 ft. tall: lvs. obovate or oval-obovate, glabrous below: stalk of fr. 2–3 in. long, glabrous. Cent. China.—*F. japónica,* Maxim. Lvs. small, elliptic, crenate: involucre small, slender-peduncled, half as long as the nuts. Japan. S.I.F. 1:35.—*F. orientàlis,* Lipsky (F. asiatica, Winkl.). Pyramidal tree: lvs. elliptic to oblong-obovate, nearly entire: lower prickles of the involucre changed into linear-oblong lobes. Asia Minor to N. Persia.—*F. Sièboldii,* Endl. Lvs. ovate, shortly acuminate, crenate, with 9–14 pairs of veins: lower prickles of the involucre changing into slender linear or obovate-oblong lobes. Japan. S.I.F. 1:35.—*F. sinénsis,* Oliver (F. sylvatica var. longipes, Oliver). Tree, about 50 ft. tall: lvs. ovate or rhombic-oval, finely pubescent below: stalks of fr. 1½–2 in. long, pubescent above. Cent. China.

Alfred Rehder.

FALLÙGIA (after Virgilio Fallugi or Falugi, an Italian botanical writer, end of the seventeenth century). *Rosàceæ.* Ornamental woody plant sometimes cultivated for its handsome white flowers and the attractive heads of feathery tailed fruits.

Deciduous shrub: lvs. alternate, small, 3–7-lobed at the apex, stipulate: fls. 1–3, terminal on elongated branchlets, perfect or polygamous, with 5 narrow bracts inserted between the calyx-lobes; calyx-tube cupular; sepals 5, imbricate; petals 5, suborbicular, yellowish white; stamens numerous in 3 rows; pistils many, on a conical torus, pubescent; style slender: achenes with long persistent plumose styles.—One species in S. W. N. Amer.

This plant is a low divaricate shrub with slender spreading branches, and conspicuous white flowers at the tips of slender branchlets, followed by dense heads of feathery tailed fruits. Hardy as far north as Massachusetts; demands well-drained soil and a sunny warm position; likes limestone soil; stagnant moisture, particularly during the winter, is fatal to it. Its best place is in a rockery of southern aspect. Propagation is by seeds, which are freely produced.

paradóxa, Endl. Shrub, to 3 ft.: lvs. cuneate with 3–7 narrow-oblong lobes decurrent into the linear petiole, revolute at the margin and whitish tomentose below, ⅓–½in. long: fls. 1–3, 1–1½ in. across, white: achenes with feathery tails 1–1½ in. long. June–Aug.; fr. Aug.–Oct. Calif., Nev. and Utah south to Mex. B.M. 6660. M.D.G. 1900:207.

Alfred Rehder.

FARADÀYA (Michael Faraday, famous chemist, 1794–1867). *Verbenàceæ.* Climbing shrubs, allied to Clerodendron, with opposite simple lvs., and fls. in terminal or nodular panicles; corolla tubular, widened upward, with a 4-lobed limb of which one lobe is larger; stamens 4, paired, exserted; ovary 4-lobed and 4-celled: fr. a drupe. There are about a half-dozen species in Austral. and S. Pacific islands. They appear not to be in the trade. *F. spléndida,* Muell., of Austral., may occur in choice collections: it is a tall glabrous climber with ovate, acuminate coriaceous lvs. 6–12 in. long, and large white fls. in terminal panicles.

FARFÙGIUM: *Ligularia.*

FÁTSIA (from a Japanese name). *Araliàceæ.* Half-hardy shrubs or small trees, used for subtropical foliage effects in the North, and planted permanently far South.

Fatsia has 2 species, belonging to the Panax series, in which the petals are valvate, while in the Aralia series they are more or less overlapping, but the sides affixed at the base. Within the Panax series, Polyscias has the pedicel articulated under the fl., while in Fatsia and Acanthopanax the pedicel is continuous with the fl. Fatsia is distinguished from the hardier and less familiar but worthy Acanthopanax by the greater length and distinctness of the styles. This genus is doubly interesting as producing the famous rice paper of the Chinese, and two rivals of the castor-oil plant in bold subtropical effects, made by large lvs., the lobes of which spread out like fingers.

1477. Good specimen of purple beech.—Fagus sylvatica var. purpurea.

While fatsias require more care in the North than the hardy aralias, their massive subtropical appearance is highly distinct. A perfect specimen is figured in Gardening 5:133, where W. R. Smith says of *F. papyrifera:* "This plant produces the beautiful substance known as rice paper; it grows to 10 ft. high, with a st. 4 in. diam., full of white pith like the elder; in a full-grown specimen the pith is about 1 in. diam. It is divided into pieces 3 in. long, and by the aid of a sharp instrument is unrolled, forming the thin, narrow sheets known as rice paper, greatly used by the Chinese for drawing figures of plants and animals, and also for making artificial fls. Until about 1850 the source of this substance was unknown to scientists. The Chinese, on inquiry, gave very fanciful figures and descriptions of it. . . . It is destined to be a people's plant, as ½in. of the root will grow and form a good plant the first season. It has survived most winters for the past 5 years in Washington, D. C."

As associates in groups of bold-habited plants, F. W. Burbidge (Gn. 45, p. 321) suggests *Polygonum sachalinense, Chamærops Fortunei* and *Rodgersia podophylla.* For contrast with feathery and cut-leaved foliage, he suggests bamboos, aucubas, cut-leaved maples and various ivies. Fatsia may be grown in the temperate house in the North, outdoors southward. It is easily grown and propagated. The species are unarmed; the very spiny plant sometimes referred to this genus as *F. horrida,* is treated under Echinopanax, which see. Siebert and Voss declare that most of the plants sold as *Fatsia japonica* are *Aralia spinosa.* These plants like shade. Full sunlight for an hour or two in early morning is enough. They should have a shelter-spot, where the wind will not whip their foliage.

1478. Fatsia japonica.

papyrífera, Benth. & Hook. (*Aràlia papyrífera,* Hook. *Tetrapànax papyríferum,* Koch.). Height 5–7 ft. (according to Franceschi, 20 ft. in the open ground in S. Calif.): branches and young lvs. covered with stellate, more or less deciduous down: mature lvs. reaching 1 ft. long, cordate, 5–7-lobed; lobes acute, serrate; sinus very deep: fls. inconspicuous, white, in sessile, globose clusters. Formosa. B.M. 4897. A.F. 7:385. Gng. 5:133. Gn. 45, p. 321.

japónica, Decne. & Planch. (*Aràlia japónica,* Thunb., not Hort.? *A. Sièboldii,* Hort.). Fig. 1478. Lvs. downy at first, finally shining green: fls. in umbels. Japan, China.—Abroad are cult. forms with white or golden margins and a form reticulated with gold markings. Var. **Mòseri,** Hort., is regarded as an improved, more compact-growing variety which originated with Moser of Fontainebleau. Intro. into Amer. by Montarioso Nurseries, Santa Barbara, Calif.

WILHELM MILLER.
N. TAYLOR.†

FÈDIA (application doubtful). *Valerianàceæ.* One glabrous branching annual of the Medit. region, sometimes grown as an ornamental and also as a salad plant. Lvs. entire or dentate: fls. red, small, in more or less dense terminal cymes; peduncles thick and fistular; corolla with an elongated tube and a 2-lipped limb, irregular at the base; stamens 2; style entire or 2–3-fid. *F. Cornucòpiæ,* DC. (*Valeriàna Cornucòpiæ,* Linn.), a variable species, usually with purplish sts., grows 10–16 in. high: lvs. nearly all radical, oval-oblong, shining green. It is sometimes known as African valerian. The lvs. are eaten as salad, being related to corn-salad. The plant seems not to be in the American trade.

FEIJÒA. The FEIJOA, or PINEAPPLE GUAVA (*Feijòa Sellowiàna,* Berg, family *Myrtàceæ*) is indigenous to western Paraguay, southern Brazil, Uruguay, and parts of Argentina, where it is common in the forests, and the fruit is highly esteemed by the natives though not cultivated. It was introduced to southern Europe in 1890, and is grown along the Riviera, both in France and Italy. From the former country it was introduced to the United States about 1900, and is becoming widely planted in California. Its distribution in other countries is very limited.

Feijoa is of 2 species. It is the Orthostemon of Berg, not of Robert Brown. *F. obovàta,* Berg (*O. obovàtus,* Berg), is considered by Niedenzu to be a variety of *F. Sellowiana.* It is a white-tomentose shrub, with bisexual showy fls.; petals 4, spreading; stamens numerous, in many series, colored; ovary 4-celled, bearing a thickish style; pedicels 1-fld., at the ends of the branches or becoming lateral. The other species is *F. Schenckiàna,* Kiaersk., of Brazil, described first in 1891. The genus is closely allied to Psidium, but is distinguished by the albuminous seeds and stamens suberect in the bud.

The plant grows to an ultimate height of 15 feet. Its leaves are similar in form and appearance to those of the olive, but larger, the upper surface glossy green, and lower surface silvery gray, forming a contrast that makes the shrub effectively ornamental. This effect is much heightened by its flowers which are produced in late spring and are 1½ inches in diameter, composed of four cupped petals, white outside and purplish crimson within, surmounted by a tuft of crimson stamens 1 inch long. The oval or oblong fruits, 2 inches in length and 1½ inches in thickness, ripen in autumn and early winter. The skin is dull green, with sometimes a touch of crimson on the cheek; it incloses a layer of whitish, granular flesh, which surrounds a quantity of translucent, melting pulp, containing twenty to thirty seeds. The flavor bears a pronounced resemblance to that of the pineapple, this being enhanced by the fact that the seeds are so small that they cannot be felt in the mouth. While commonly eaten fresh, the fruit may be cooked in several ways, crystallized, or made into jam or jelly.

The feijoa does not seem to thrive under strictly tropical conditions, preferring a climate such as that of southern California or the Riviera, free from excessive humidity, and cool at least part of the year. In France, the plants have passed uninjured through temperatures of 12° F. A good loam, rich in humus, is the ideal soil for the feijoa. It has been successfully grown on heavy clay, by working in a quantity of light material, but it does not do well on light or sandy soils. The situation seems to be of little importance, provided the land is well drained. While the plant is notably drought-resistant, for best results in growth and fruiting a liberal supply of water is necessary. During the dry season, irrigations should be as frequent as for citrous trees. Fertilizers must be applied with caution, or they will stimulate growth at the expense of fruit. A small quantity of bone-meal, or other fertilizer not too rich in nitrogen, may be advantageously applied each year, while well-rotted manure will supply the much-needed humus, if it is lacking in the soil. The plants should be set 15 or 18 feet apart, and require very little pruning. Seedlings usually come into bearing at three to five years; grafted or layered plants will sometimes bear the second year.

In some instances, seedling feijoas fruit sparingly or not at all, either through the failure of the flowers to be properly fertilized or because of unfavorable soil or surroundings. Although isolated plants are often productive, it has been suggested that the feijoa is sometimes self-sterile, and two or more bushes should be planted together to permit of cross-pollination. The difficulty can probably be obviated, in a measure at least, by propagating asexually from strains of known productiveness.

The fruits fall when mature, and must be laid in a cool place until they are in condition for eating, which can be detected by a slight softening, and also by the odor,—a fragrance most delightful. If picked before fully mature and ready to fall, the fruits lack much of the delicate flavor of a perfectly ripened specimen. Very little care is required in packing, and the fruits can be shipped long distances without difficulty. They spoil quickly in a hot, humid atmosphere, but if stored in a cool place they can be kept for a month or more in perfect condition.

The shrub is attacked by a very few insects, the only one noted in either California or southern Europe being the black scale (*Saissetia oleæ*), which rarely requires combative measures. No fungous diseases have been observed on mature plants.

Propagation is usually by seed, but some vegetative means must be used to perpetuate named varieties. Fruits for seed should be selected with a view to desirability in every character, as in precocity of bearing and productiveness of the parent. While the feijoa does not come absolutely true from seed, fairly good results are usually secured from selected seeds.

One of the best mediums for germinating the seeds is a mixture of silver-sand and well-rotted redwood sawdust. This gives an almost sterile medium, in which there is little danger of damping-off, to which fungus the young plants are very susceptible. With care in watering, however, any light porous soil, not too rich in humus, may be used. Sow the seeds in pans or flats, covering them to the depth of ¼ inch. Germination will usually take place within three weeks. A glasshouse is not necessary, but the flats containing the seeds should be kept in a frame with lath or slat covering to provide partial shade. The seeds will retain their vitality a year or more, if kept dry. As soon as the young plants have made their second leaves they should be pricked off into 2-inch pots; after attaining a height of 4 inches they should be shifted into 3-inch pots, from which they can later on be transplanted into the open ground.

Cuttings can be successfully rooted under glass. They should be of young wood from the ends of branches, and about 4 inches in length. Inserted in clear sand over bottom heat they will strike roots in a month or two; without bottom heat they root very slowly. It is sometimes advised to keep them covered with bell-jars until they have formed roots.

Layering is used in France to perpetuate choice forms. It is somewhat tedious, but more certain than any other vegetative means of propagation. Those branches which are closest to the ground are bent down and covered with soil for the space of 3 to 6 inches. They require no care except to keep the soil fairly moist, and they will root in six months.

Whip-grafting and veneer-grafting are successfully practised under glass, using as stocks seedling feijoas of the diameter of a lead pencil. The cions should be of about the same diameter and of young but firm wood.

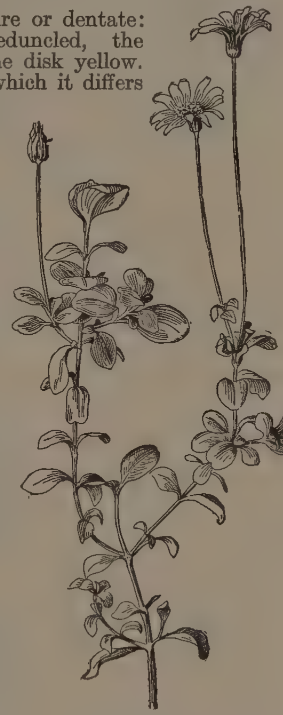
Several named varieties have been established, of which the most prominent are André and Besson.

F. W. Popenoe.

FELÍCIA (for Herr Felix, a German official). *Compósitæ.* Herbs or sub-shrubs, grown under glass or as pot specimens.

Leaves alternate, entire or dentate: heads usually long-peduncled, the corolla blue or white, the disk yellow. Much like Aster, from which it differs in having pappus bristles in one series, and in other technical characters.—Forty to 50 species in Afr.

amelloìdes, Voss, not Schlechter 1898 (*Cinerària amelloìdes*, Linn. *Áster rotundifòlius*, Thunb. *A. capénsis*, Less. *Agathæa cœléstis*, Cass. *A. rotundifòlia*, Nees. *A. amelloìdes*, DC.). Blue Daisy. Blue Marguerite. Fig. 1479. An old greenhouse plant, 1–2 ft., with roundish ovate opposite lvs. and large, solitary heads of an exquisite sky-blue. S. Afr. B.M. 249. A.F. 13:657. F.R. 1:674. Gng. 6:149.—There is a variegated-lvd. variety (I.H. 8:296). Grown easily from cuttings. Handled like a cineraria; or, if grown from spring cuttings for winter bloom, like a chrysanthemum, but with more heat in the fall. An elegant pot-plant, and useful for bedding in a protected place. Var. **monstròsa**, Hort. Fls. double the size of the type.



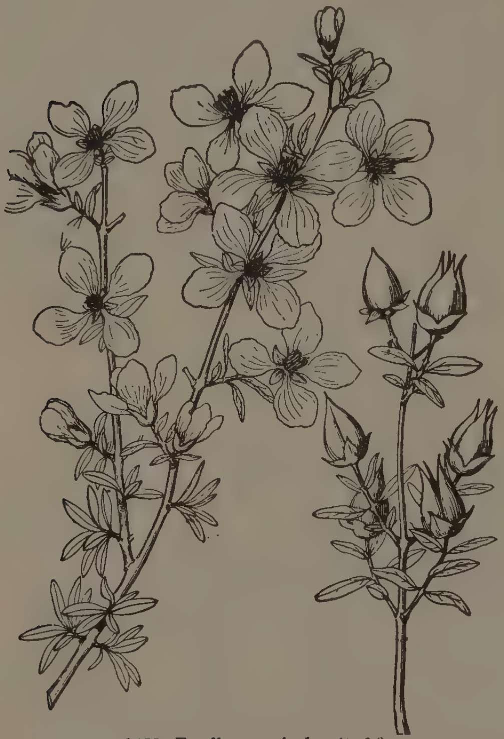
1479. Blue daisy.—Felicia amelloides. (×⅛)

petiolàta, N.E. Br. (*Áster petiolàtus*, Harvey). An undershrub more or less prostrate and useful for hanging-baskets: lvs. obovate or lanceolate, wedge-shaped at the base, rather papery: fls. at first rose-colored, gradually changing to aster-blue. S. Afr. B.M. 8370. F.E. 33:503. G.C. III. 42:82.—Intro. in S. Calif. in 1912.

N. Taylor.†

FENDLÈRA (after Augustus Fendler, a German naturalist, botanical explorer of New Mexico). *Saxifragàceæ.* Ornamental woody plant grown for its handsome white flowers.

Deciduous shrub: lvs. opposite, short-petioled, entire, 3-nerved: fls. solitary or rarely 2–3 at the end of short lateral branchlets; calyx-lobes and petals 4; stamens 8: ovary almost superior: fr. a 4-celled, dehiscent caps., with flat, oblong seeds.—Two species from Texas to Mex. Allied to Philadelphus, but differing in its 8 stamens and superior ovary. They are graceful ornamental shrubs with small, grayish foliage, covered in June along the slender, arching branches with graceful white fls., resembling in shape a Maltese cross. Hardy in New England, and growing best in a well-drained, sandy or peaty soil and sunny position. A very handsome and graceful plant for sunny rockeries or rocky slopes. Prop. by seeds or by greenwood cuttings under glass.



1480. Fendlera rupicola. (×⅔)

rupícola, Engelm. & Gray. Fig. 1480. To 4 ft.: lvs. linear-lanceolate or linear-oblong, 3-nerved, revolute at the margin, grayish tomentose beneath, ½–1 in. long: fls. milky white, 1 in. across; petals rhombic-ovate, with distinct claw, spreading; stamens erect. June. G.F. 2:113 (adapted in Fig. 1480). G.C. III. 36:410. B.M. 7924. R.H. 1891, p. 42; 1899, p. 129. M.D.G. 1899:231. G. 28:601. Alfred Rehder.

FENNEL. Species of *Fœniculum* (Umbelliferæ), annuals or treated as such, used as salad or condimental herbs. Native of southern Europe. The common fennel (*F. officinàle*, Linn.) is grown mostly for its young leaves, which are used in flavoring, and also for its aromatic seeds. Leaves sometimes eaten raw. Sow seeds in late fall to ensure early germination in spring, or sow in early spring. In any good soil, the plant comes to maturity quickly. This plant has become in California one of the most widely naturalized European weeds. It is a pest in pastures, said at times to attain 12 or 15 feet.

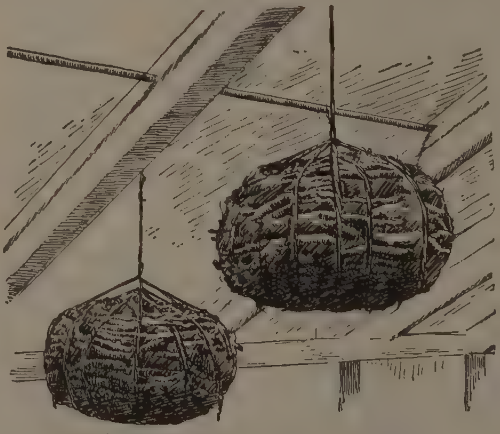
The Florence or sweet fennel is *F. dulce*, DC. The bases of the crowded leaf-stalks are much thickened, making a bulb-like enlargement above the ground. This thickened base has an oval form in cross-section. Earthing-up blanches these thickened leaf-bases, and after boiling they are fit for eating. A good fennel bottom may be 3 or 4 inches high. This is an Italian vegetable, but is in the American trade. Easily cultivated annual; matures quickly. Sow in spring, and later for succession.

Giant fennel is cultivated for ornament, and is described under *Ferula*. Fennel-flower is a name of Nigella. L. H. B.

FENUGREEK (*Trigonella Fœnum-Græcum*, literally Greek hay). An annual legume indigenous to western Asia, cultivated for human food, forage, and for medicinal qualities; widely naturalized in Mediterranean countries; little grown in America.

Fenugreek is an erect little-branched plant with 3-foliolate leaves. The seeds are 1 or 2 lines long, brownish yellow and marked with an oblique furrow half their length. They emit a peculiar odor, and contain starch, mucilage, a bitter extractive, a yellow coloring matter, and 6 per cent of fixed and volatile oils. As human food they are used in Egypt, mixed with wheat flour, to make bread; in India, with other condiments, to make curry powder; in Greece, either boiled or raw, as an addition to honey; in many oriental countries, to give plumpness to the female human form. The plant is used as an esculent in Hindostan; as an early fodder in Egypt, Algiers, France, and other countries bordering the Mediterranean. Formerly the seed was valued in medicine; now it is employed only in the preparation of emollient cataplasms, enemata, ointments and plasters, never internally. In veterinary practice it is still esteemed for poultices, condition powders, as a vehicle for drugs, and to diminish the nauseating and griping effects of purgatives. It is commonly used by hostlers to produce glossy coats upon their horses and to give a temporary fire and vigor; by stockmen to excite thirst and digestion in fattening animals; by manufacturers of patent stock foods as a flavoring ingredient.

Fenugreek does not succeed on clays, sands, wet or sour soils. It yields most seed upon well-drained loams of medium texture and of moderate fertility; most fodder upon rich lands. For seed-production, potash and phosphoric acid should be applied; for forage, nitrogenous manures. Deep plowing and thorough harrowing are essential. Ten to twenty pounds of seed should be used broadcast, or seven to ten pounds in drills 18 inches apart. Thinning when the plants are 2 or 3 inches tall, and clean culture throughout the season until blossoming time, are necessary for a seed crop. The crop may be mown, dried and threshed four or five months after seeding. An average yield should be about 950 pounds an acre. As a green manure, fenugreek is inferior to the clovers, vetches and other popular green manures of this country. It possesses



1481. Fern-balls as received from the dealer.

the power of obtaining nitrogen from the air by means of root-tubercles.—For description of the plant, see *Trigonella*.
M. G. Kains.

FÉNZLIA: *Gilia.*

FERDINÁNDA: *Podachænium.*

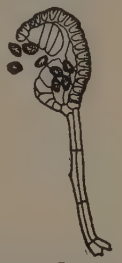
FERN-BALLS (Fig. 1481) are the dried rhizomes of ferns, imported from Japan. Dealers often start them into growth, and sell them when the mass is well covered with its delicate vegetation. To start them into growth, the balls are drenched in a tub of water and then hung in a warmhouse, not in direct sunlight. When the plants are well started, gradually expose them to more light and to a cooler air. Give liquid manure if they do not grow satisfactorily. The species are mostly Davallias, apparently *D. bullata* and *D. Mariesii*.

Fern-balls (*Davallia bullata*) are of Japanese origin. They are natives of deep mossy forests (the mosses on trees as well as on the ground), with abundant humidity in the air, as in Kiso or some parts of Fukushima districts. Toward the end of every winter, an expert goes into these forests and gathers the vines of such ferns. They should be carefully kept in the bamboo baskets in which a large quantity of mosses are contained, which must be sprinkled with water on the way to the metropolis. The people outside of large towns or cities do not care much for this plant. When the plants arrive in the cities or towns, they fall into the hands of gardeners who make many shapes with the vines (Fig. 1482). This is done before any leaves appear. Then the balls or other shaped articles are hung from the ceiling beam quite near to its end but not exposed to rain or hot sunshine. The ferns should not be subjected to pouring rain or showers, although they like dew. They should have some sprinkling of cool water once every day after sunset. The plant dislikes dust or warm impure water. The best fertilizer is the extract of fish-meal or cake ("abura-kasunazumi"). Prices run from 20 cents to 50 cents United States money according to the shape of balls and general excellence. (Issa Tanimura.)

1482. Ferns in formal shapes.

FERNÈLIA (Jean François Fernel, 1497–1558, physician to Henry II of France). *Rubiàceæ.* Four small evergreen trees or shrubs of the Mascarene Isls., rarely grown in choice warmhouse collections. Lvs. small, opposite, coriaceous, short-stalked, ovate-oblong or nearly orbicular: fls. small, solitary or in 2's, provided with a 4-toothed calyx-like involucre; corolla short-tubed, salver-shaped, with 4 spreading lobes; stamens 2, affixed in the corolla-throat; disk annular; ovary 1-celled below and 2-celled above: fr. a small berry. *F. buxifòlia*, Comm., is the species likely to be in cult. It is a much-branched shrub 4–5 ft. high, with obovate or oblong lvs. ½in. or less long, and many whitish fls. in the axils of the lvs.: berry dry, size of a pea, red, borne inside the involucre. Mauritius.
L. H. B.

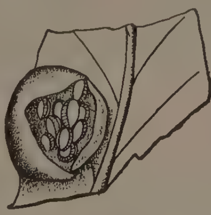
FERNS. The plants included under this name comprise an entire order, made up of several distinct families. They include plants varying in size from a hair-like creeping stem bearing a few simple, moss-like leaves, to tall trees 80 or more feet in height, with a stem or trunk nearly a foot in diameter. Singularly enough, the extremes in size are both found in tropical regions, in which most of the species abound. Most of the ordinary native species, as well as the larger part of those in cultivation, consist of an erect underground stem or rootstock with leaves, often called fronds, clustered in dense crowns, or in the cases of creeping stems with scattered leaves. In gardening parlance, other plants are sometimes called ferns, as species of lycopodium and selaginella, as well as *Asparagus plumosus.*



1483. Sporangium or spore-case of a fern.

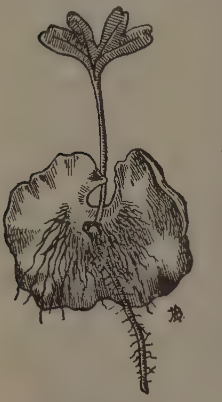
In the life of an individual fern plant, two distinct phases occur, represented by two separate and unlike plants. The ordinary fern plant represents the asexual phase of growth (*sporophyte*), producing its spores normally in spore-cases (*sporangia*, Fig. 1483), which are borne in masses (*sori*, Fig. 1484) on the back or margin of the leaf, or in a few cases are grouped in spikes or panicles, or in rare cases spread in a layer over the entire under surface of the leaf. The sexual stage (*gametophyte*) develops from the germinating spore, and consists of a tiny usually scale-like green heart-shaped prothallus (Fig. 1485), which bears the sex-organs (*archegonia*, female, and *antheridia*, male) on the under surface. After fertilization in the archegonium, the egg develops directly into a young fern plant (Fig. 1485). Many ferns also propagate vegetatively by runners or offsets, by bulblet-like buds, and in certain species the tips of the leaves bend over and take root, as in our common walking-leaf (Camptosorus, which see).

Ferns frequently hybridize. The crossing takes place naturally in the prothallium stage. They are not crossed by hand, as are the seed-plants, but from the accidental mixing when prothallia of allied species are growing together. Fig. 1486 (G.F. 9: 445) is a hybrid between two native species; it has been found in the wild in several parts of New England.



1484. A sorus or fruit-dot of a fern.

Great diversity has existed in the matter of the separation of the ferns into genera. Hooker, relying mainly on artificial characters drawn largely from the sorus, recognized about seventy genera only, many of them heterogeneous groups of plants with little resemblance in structure, habit or natural affinities. John Smith, relying on stem characters, Presl on variation in venation and habit, Fée, Moore, and others, have recognized a much greater number of genera, ranging from 150 to 250, or even more. In the very unequal treatment by Diels in Die Natürlichen Pflanzenfamilien (Engler & Prantl), some 120 genera are recognized. A somewhat similar difference prevails in regard to the number of species. The Synopsis Filicum of Hooker and Baker (1874), supplemented by Baker's New Ferns (1892), recognizes some 2,700 species. It is the too prevailing tendency in this work (1) to fail to recognize many valid species which have been described by German and French botanists, and (2) to mass under one name very diverse groups of species from distant quarters of the world—from 8 to 10 species not infrequently appearing as a single so-called "variable species." The most recent book dealing with the whole order of ferns, the Index Filicium by Carl Christensen, recognizes approximately 150 genera and 6,000 species, and this number is continually increased as the result of further tropical exploration and more careful study. New forms are constantly coming in from the less-explored parts of the world, and within the last few years several new species have been described from the United States, including some from the better-known parts. Of this number some 200 species are in occasional cultivation in America, but the species that form the bulk of the fern trade do not exceed two dozen. In Europe several hundred species have long been in cultivation. Most of the species thrive best in the mountain regions of the tropics, the mountains of Jamaica and Java having nearly 600 species each, and the Andes also a large number. About 165 species are native in the temperate United States, representing some thirty-five genera; our native species are so widely distributed that usually not more than twenty-five to fifty will be found within the limits of one state, and the common species of the best locality do not number more than twenty. Recent explorations in southern Florida have discovered in that state the presence of a considerable number of West Indian species not found elsewhere in the United States.



1485. Prothallus of a fern, with a young leaf arising.

The ferns are commonly classified as part of a group of spore-bearing plants, with vascular (woody) tissue in stem and leaves; this group is technically known as the Pteridophytes, and is ordinarily divided into three orders; viz., the **Equisetales,** including the horsetails and scouring rushes; the **Lycopodiales,** including the selaginellas and the club mosses, or ground pines; and the **Filicales,** including the true ferns and their nearer allies (see pp. 7–9, Vol. I). The Lycopodiales and Equisetales are really not as closely related to ferns as this grouping would indicate.

It should be noted that neither the family nor the generic limitations are in a settled condition. The researches of Bower, Lang, Jeffrey, and others have resulted in some changes of classification which are not included below because they are not complete enough. Their conclusions are undoubtedly correct but are not at present usable.

The families of the order **Filicales** may be distinguished as follows:

A. *Spores of one sort. (Isosporous.)*

B. *Sporangia fleshy, with no ring, rising from the interior tissues of the lf. (Eusporangiate ferns.)*

1. **Ophioglossàceæ.** ADDER'S-TONGUE FERNS. Herbaceous small ferns with the sporangia borne in spikes or panicles on highly modified divisions of the large fleshy foliage lvs.; prothallium tuberous, subterranean, without chlorophyll.

2. **Marattiàceæ.** Coarse ferns with large fleshy sporangia on the under surface of the lf., arranged in circular or boat-shaped receptacles; prothallium above ground, green.

BB. *Sporangia rising from an epidermal cell, with an elastic ring of peculiar cells, which assist in scattering the spores by rupturing. (Leptosporangiate ferns).*

C. *Lvs. filmy, usually only 1 cell thick between the veins.*

3. **Hymenophyllàceæ.** FILMY FERNS. Sporangia attached to a thread-like receptacle arising in a cup at the end of the lf.: ring complete, horizontal or oblique.

CC. *Lvs. herbaceous or leathery.*

D. *Ring incomplete or rudimentary: sporangia in panicles.*

4. **Osmundàceæ.** FLOWERING FERNS. Coarse swamp ferns developing copious green spores early in the season: sporangia in panicles at the apex or middle of the lf. or on separate lvs.

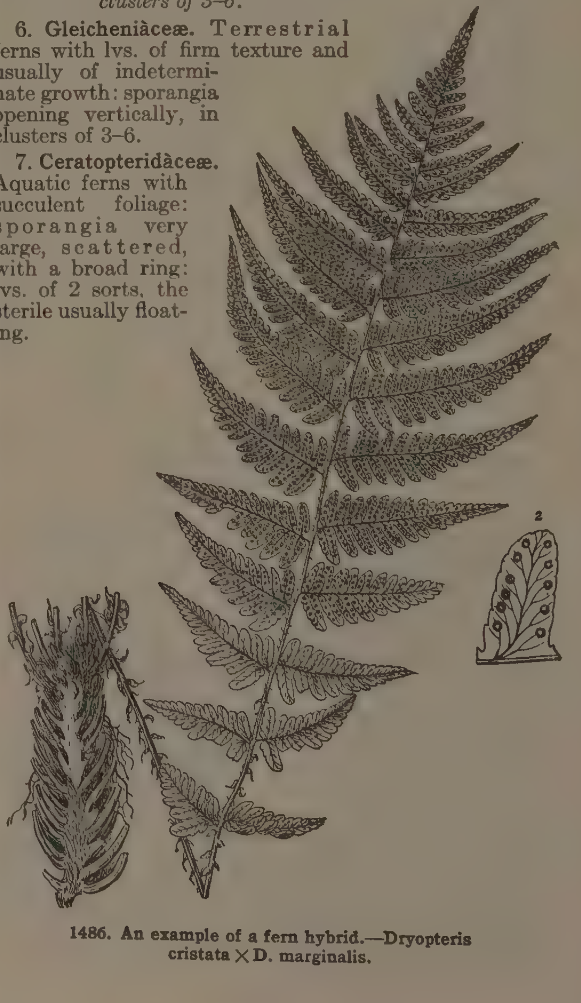
DD. *Ring apical: sporangia usually single under a scale, or in panicles.*

5. **Schizæàceæ.** Upright or climbing ferns with ovate sporangia, which open vertically.

DDD. *Sporangia sessile, either single or in clusters of 3–6.*

6. **Gleicheniàceæ.** Terrestrial ferns with lvs. of firm texture and usually of indeterminate growth: sporangia opening vertically, in clusters of 3–6.

7. **Ceratopteridàceæ.** Aquatic ferns with succulent foliage: sporangia very large, scattered, with a broad ring: lvs. of 2 sorts, the sterile usually floating.



1486. An example of a fern hybrid.—Dryopteris cristata × D. marginalis.

DDDD. *Sporangia numerous, collected in definite clusters (sori).*

8. **Cyatheàceæ.** Mostly tree ferns with sessile or short-stalked sporangia in conspicuous receptacles, opening obliquely (Fig. 1179, Vol. II).

9. **Polypodiàceæ.** Ferns with stalked sporangia (Fig. 1483), which burst transversely: sori covered with a membranous indusium or sometimes naked. This family contains three-fourths of all the ferns.

AA. *Spores of two sorts: minute microspores and conspicuous macrospores. (Heterosporous.) These spores develop into two sorts of prothalli, those from the microspores developing only antheridia, and those from the macrospores only archegonia.*

10. **Marsiliàceæ.** Small plants rooting in mud, the lvs. either quadrifoliate or reduced to mere filamentous petioles: sporangia borne in oval conceptacles on the leaf-stalks. Often aquatic, with the leaves floating on the surface of water in pools or lakes.

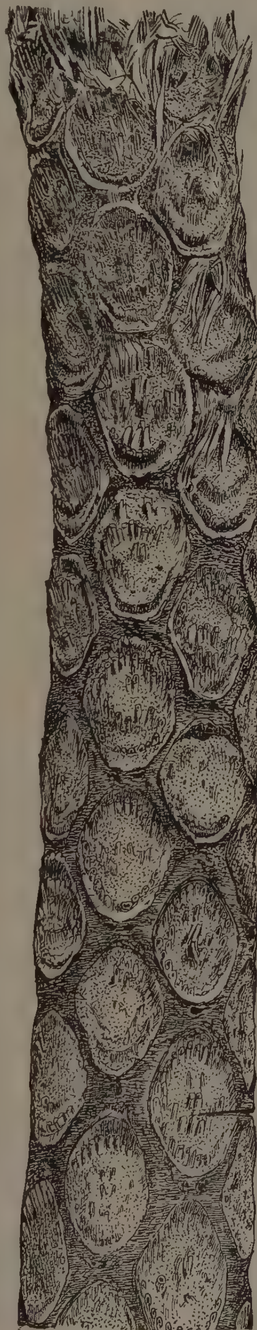
11. **Salviniàceæ.** Small or minute plants with the aspect of liverworts, floating on the surface of pools: sporangia in mostly spherical conceptacles.

The literature on the ferns is very extensive, since they have ever been attractive plants in cultivation. Many of the species have been illustrated in elaborate treatises by Schkuhr, Kunze, Hooker, Greville, Blume, Fée, Mettenius, Moore, and others. Our native species have been illustrated in the two quarto volumes of D. C. Eaton, "The Ferns of North America." A valuable summary of the more common fern species is found in Dr. Christ's "Die Farnkräuter der Erde" (1897), and a recent structural and morphological treatment is by Sadebeck, in Engler & Prantl: "Die Natürlichen Pflanzenfamilien." Schneider's "Book of Choice Ferns" is the most complete treatise on the species under cultivation. A useful American horticultural manual is Robinson's "Ferns in Their Homes and Ours." An excellent little handbook for the wild species of this country is Underwood's "Native Ferns and Their Allies."

L. M. UNDERWOOD.
R. C. BENEDICT.†

Tree ferns.

The term "tree fern" is applied commonly to ferns of the family Cyatheaceæ, to distinguish them from species of other families of ferns which, for the most part, are not at all arborescent. A comparatively small number of Cyatheaceæ, it is true, have the trunk short, and oblique or decumbent; but in most species the trunk is erect and greatly elongate (commonly 3 to 40 feet high) and the whole plant so unmistakably tree-like in size and proportion, that the name "tree fern" is a most appropriate one for the family. The leaves are usually large and are borne in a radiating palm-like crown at the apex of the trunk, or caudex, as it is often called. The trunk itself, in the case of an ordinary mature individual, is marked by numerous close-set leaf-scars (Fig. 1487); these serve to indicate not only the relatively great age of the plant but its slow rate of continuous development, as well.



1487. The trunk of a tree fern.—Cyathea arborea.

Tree ferns are primarily forest dwellers and occur either as component parts of the dominant forest growth or, more commonly, as a sort of thicket or "under-forest" association in moist partial shade beneath the crowns of the higher forest trees. They are nearly confined to wet tropical mountain slopes which are not subject to drought or pronounced seasonal change; they reach therefore, their best development, both as to species and number of individuals, upon lofty mountains and upon the seaward side of ranges which are drenched constantly by cool moisture-laden winds from the ocean.

The successful cultivation of tree ferns under glass is predicated upon these facts, although not all the species here mentioned are horticulturally known in this country. It is found that most species should be grown at a temperature of about 60° F. and in a rather shallow soil; that a continuously wet but well-drained substratum is essential; and that in general a tolerably high atmospheric humidity also is requisite for best growth. Very bright sunlight must be guarded against in all but a few species, among these being the common tropical American *Cyathea arborea,* which grows naturally in rather open places, and *C. furfuracea,* a native of Cuba and Jamaica which assumes a not unattractive form in drier open situations. As in other groups of ferns, there are certain species which demand unusual care and minor variations of treatment, such as wrapping the trunk in sphagnum as a safeguard against drying out. These special requirements can be determined only by experience.

The Cyatheaceæ are divided technically into three tribes: Thyrsopterideæ, Dicksonieæ, and Cyatheæ. The first mentioned consists of a single species, *Thyrsopteris elegans,* Kunze, from Juan Fernández. The two latter tribes may be distinguished as follows:

Sori terminal upon the veins, at or near the margin of the segments; indusia at least bilobed, the outer lip formed of the more or less modified lobule of the leaf..... **Dicksonieæ.**
Sori borne upon the back of the veins; indusium (if present) not formed of the leaf-margin in any part **Cyatheæ.**

The Dicksonieæ consist of three genera: Culcita (often known as Balantium), with about six species, all of small stature and nearly devoid of trunk; Dicksonia, with five tropical American species and several hardy Australasian species, the latter not uncommon in cultivation and capable of enduring unusually great extremes of cold; and Cibotium, with four North American species and several which occur in Asia and the islands of the Pacific. (See under *Cibotium* and *Dicksonia.*)

It is in the Cyatheæ, however, that the greatest variety and extremes of leaf form are noted, and consequently the species of this tribe are most highly esteemed in cultivation. They are commonly associated under three genera: Cyathea, Alsophila, and Hemitelia, distinguished mainly by characters of the indusia. One of the most graceful species of all is *Cyathea arborea*, introduced into England from the West Indies by Admiral Bligh in 1793. There are numerous species almost equally fine, many of which are not in general cultivation. The species with clean trunks, from which the leaves are freely deciduous after maturity, are the most pleasing; and among those which deserve especial notice are the following: *Cyathea minor*, a very slender Cuban plant with trunk 6 to 12 feet high and 1 to 1½ inches thick, its several slender bipinnate leaves borne in a spreading crown; *C. portoricensis*, a tall Porto Rican species with large nearly tripinnate leaves, its rachises dark, lustrous, purplish brown; *C. elegans*, of Jamaica, a close ally of *C. arborea*, often attaining a wide spread of leaf at an unusually early age; *C. Werckleana*, *C. hemiotis*, and *C. hastulata*, of Costa Rica, a peculiar subgroup characterized by having the leaves fully tripinnate, the ultimate rachises discontinuously alate; *C. divergens*, extending in one form or another from the Andes to Costa Rica, its huge fronds exceedingly lax and sometimes even in large plants recurved nearly to the ground; *C. insignis* of the Greater Antilles, in technical characters allied to the well-known *C. princeps* of Mexico; *C. suprastrigosa* and *C. conspersa* of Costa Rica and Panama, delicate graceful tripinnatifid plants of the high mountains; *C. punctifera* of Nicaragua and Costa Rica, a plant of lower range, its huge tripinnatifid fronds remarkably beautiful from the strong contrast afforded by the slender rich brown rachises and the unusually vivid green leaf-segments; *C. aureonitens* of Costa Rica and Panama, a lofty plant with leaf-scars in distant zones, having the unusual habit also of shedding piecemeal all its large tripinnatifid fronds, seasonally.

Of Alsophila, the two best-known species in cultivation are doubtless *A. australis* and *A. aspera*, the latter a common West Indian plant. *A. myosuroides*, of Cuba, Mexico, and Central America, has lately been reintroduced to cultivation. It is a remarkably handsome plant, its rather harsh, heavy, gray-green, tripinnatifid leaves borne from a copious mass of slender, glossy brown scales. Another beautiful species, *A. Salvinii*, from Mexico and Guatemala, has very large tripinnate fronds, with woody castaneous rachises in striking contrast. A favorite species in cultivation also is *A. quadripinnata* (*A. pruinata*), native in the West Indies and from Mexico to Chile, its short trunk bearing huge four-pinnate fronds, bluish or silvery white beneath.

The genus Hemitelia includes not only plants of the above sort, with tripinnatifid fronds (as, for example, the well-known *H. capensis*), but also plants of a distinctly different type known as the subgenus Cnemidaria. These are *H. horrida*, of the West Indies, and numerous related species of the American tropics, many of which have long been cultivated in European conservatories. They are characterized mainly by short trunks and large, leafy, simply pinnate or bipinnatifid fronds, and make a beautiful display in cultivation. Among them may be mentioned *H. speciosa*, *H. bella*, *H. grandifolia*, (*H. insignis*), *H. spectabilis*, and *H. subincisa*. Their characters have recently been discussed at some length. (See Contr. U. S. Nat. Herb. 16:25–49, 1912.)

Considering the wealth of material available in the American tropics and the comparative ease with which it may be secured, it is remarkable that so little attention has been given to the introduction of recently described species. The novelty and beauty of many of these render an effort to this end exceedingly desirable and advantageous from a horticultural point of view. Costa Rica in particular has yielded many interesting new species within late years. This region, which has been called the richest in the world, will doubtless be equaled by certain parts of the Andes of South America, when that immense territory shall have been adequately explored. William R. Maxon.

Cultivation of tender ferns.

To grow commercial varieties of ferns profitably, the first care should be to secure the necessary number of properly built and equipped houses, with a conveniently arranged workshop. The house which gives the most general satisfaction runs north and south, has an even-span roof, and with a fall to roof of 6 inches to the foot. Its benches should be arranged to be about 7 feet wide, with a 24-inch path on either side. In an 18-foot house this will permit of having a 7-foot center-table, two 3½-foot side benches and two 24-inch paths. Benches should not be more than 3 feet above the walks, as this will bring every part of the bench within easy reach, and will permit of every plant being in constant sight and easily cared for, which fact is essential in the profitable cultivation of trade ferns.

The width of house is immaterial, but when houses adjoin, a width of 27 feet has been found to be very satisfactory, as this permits the construction of three 7-foot benches, two 24-inch paths, and two paths 2½ feet wide under each gutter.

Thorough provision should be made for ventilation. For a 27-foot house, a continuous row of ventilators of at least 3 feet in width should be provided, with some reliable apparatus for raising same. Heating is the next important consideration. Either steam or hot water will give equally good results if properly installed. The safest way for the average grower is to give the heating contract to some reliable firm. Water-taps should be so arranged that a 25-foot hose attached to same will easily reach any part of the house. A 25-foot hose can easily be carried about without injuring either itself or benches and plants; and iron pipe is of only half the cost of good hose. In most fern-houses drip is a source of great annoyance, and should be prevented by the use of drip-bars, by having a drip-groove plowed into the headers immediately under the ventilating-sash, and also by having a groove in sides of gutter-plates. This very slight additional expense will very soon pay for itself by saving a great number of plants, especially when growing very small ferns in houses, such as have been transplanted from spore-pots into boxes. Ventilators should fit into a groove in ridge of house and be hinged to the ridge. When ventilators are so arranged, air, which is very desirable on a good many warm rainy days in the summer, can be given without having plants in the houses suffering from excessive moisture. Burning of the foliage will also be avoided, as the plants will at no time be exposed to the direct rays of the sun. Ventilators hinged on header and opening on ridge will always give trouble. No matter what kind of covering is put over the opening, if it efficiently excludes the burning sun's rays it will also prevent the ingress of air.

A propagating-room should be provided; and in the case of general trade ferns raised from spores, it is a very safe rule to calculate on having from 60 to 70 square inches of room in the propagating-frame for every 1,000 plants desired. The propagating-frame should be 3½ feet wide, have sides 9 inches high, and, to insure an even moisture, its bottom should be covered to the thickness of 1 inch with fine cinders with the fine ashes removed, which make very clean and efficient drainage material. The frame should be covered with light sash constructed with drip-bars, to carry off condensation.

Shading of fern-houses should have close attention. It is best effected by the application of a suitable wash to the outside of glass on roof. The following composition for a wash has given excellent results for a number of years: To two gallons of benzene or turpentine add one pint (or more, according to time the shading is desired to remain on houses) of linseed oil, five pounds of pure white lead and enough whitening to make proper thickness (which can very easily be ascertained by applying some of it to a piece of glass while adding the whitening); thoroughly mix and apply to outside of glass with a soft brush of the same width as glass. This shading, by the addition of more or less linseed oil, may be made to stay on houses up to one year. If properly applied in spring, it will be just right during the hot days of summer, and in the fall and winter, when more light is gradually required, the frosts gradually will have reduced the shading, thus admitting more light at the necessary time.

Much time, annoyance and expense will be saved by a careful arrangement of the workshop, or potting-room, a thing which in most cases is totally neglected. It should be so built that potting-benches are about 3 feet above the floor and 5 feet wide. They may be permanently constructed of substantial material, in order that a number of pots of different sizes can be conveniently stored, and that potting material can be thrown from cart or wagon directly onto potting-benches. By an improper arrangement of workshop great expense, loss of time and material are incurred by having to handle material repeatedly in small quantities.

Propagation by means of spores.

To grow ferns from spores successfully, it is advisable to sterilize soil on which they are to be sown, which can best be done by subjecting it to a high temperature by means of steam under a pressure of ten to fifteen pounds; and for this purpose a properly equipped workshop should be provided with a tight box about 3 by 3 by 8 feet or larger if an uncommonly large number of ferns is to be grown. It should be fitted with a grating made of 2-inch laths spaced 1 inch apart and placed 2 inches from bottom of the box. This grating may be covered with burlap, and if a ¾-inch steam pipe is fitted between bottom of box and grating, and connected to highest point of steam boiler (to insure getting perfectly dry steam), the soil is ready to be sterilized. After having cooled off, the soil is in practically the same condition as before so far as moisture, friableness, and the like are concerned, and this cannot be said of soil that has been sterilized by burning and by other methods. This steaming process will effectually destroy all forms of life in the soil and leave it for the use of spores alone. In most localities, the water used for moistening spores is impure and full of the spores of low forms of plant life, which are very destructive to the prothalli of ferns. To prevent this, the workshop should be provided with a receptacle in which the water intended for use on ferns while in the prothallus state can be raised to a boiling temperature, which will effectually destroy all spores that may be present in the water. This is best done by leading a 1-inch steam-pipe to within 6 inches of the bottom of the receptacle and turning on a reasonable pressure of steam. If boiled twelve hours before intended for use, it will be cool enough to be applied, and will be pure. A fern workshop should also be provided with a dry closet, having a number of shelves about 12 inches apart, for storing fern-spores.

In beginning the cultivation of ferns, it is advisable to purchase the spores from some reliable firm which makes fern-growing a specialty, until a sufficient number of stock plants can be grown to supply spores for home demand. Spores will do about equally well in pots or pans. Pans 12 inches square and 4 inches deep are used for that purpose, as also are the 6-inch common flower-pots. The 12-inch pans should be supplied with 1½ inches and the 6-inch pots with 3 inches of coal cinders for drainage. Soil for sowing spores on is best composed of five parts, in the proportions of two parts good garden soil, two parts of finely screened peat and one of sharp clean propagating sand. Leaf-mold may be used instead of peat, if easier to procure. This soil should be thoroughly sterilized, as already directed. The spore-pots should be filled with the soil to within ¼ inch of the top; press firmly. The rest of the pots should be filled with the same composition after it has been passed through a screen of about ⅛-inch mesh, then made absolutely level, firmly pressed and thoroughly watered with sterilized water. Three or four hours after watering will be the best time to sow spores. The spores should be thinly scattered over the surface of the soil, a quantity that can be held on a surface of ¼ square inch being abundant to sow one 12-inch pan. Spores should not be covered with soil. Immediately after sowing, the sash of the propagating-frame should be tightly closed and kept so until spores show signs of germination, when a small quantity of air should be given and gradually increased, so that by the time the first small fronds have made their appearance they may have been sufficiently hardened off to have the sash removed entirely. In sowing spores, great care will be necessary to prevent them from getting mixed, fern-spores being very minute and so light that the slightest movement of air will carry them long distances. While sowing spores, all spore-pots should be kept tightly covered. Being kept in a very close and humid atmosphere after sowing, the spores should not require any watering for one or two weeks, by which time they will have sufficiently settled not to be dislodged by a very gentle overhead watering, which should be given whenever soil shows the least sign of being dry. Sterilized water should be used until after the first delicate fronds have been formed. As soon as the first little fronds have made their appearance, care should be taken to weed out all undesirable varieties, which, even with the very best of care, will occasionally creep in. A temperature of 65° F. should be maintained in the propagating-house.

1488. A fern pan.

As soon as the first small fronds are evenly formed all over the surface of the pot, the little plants should be transferred in clumps of four or five plants each, to well-drained pans (Fig. 1488) or boxes filled with soil composed of one-half rich garden soil and one-half peat or leaf-mold, finely screened. In transplanting, great care should be exercised not to cover the remaining prothalli, but to have them just level with the surface of the soil. The clumps of plants should be kept as loose as possible, as this will give each individual plantlet a better chance to form the necessary number of rootlets, and it will, later on, also be easier to separate the plants. Boxes for transplanting ferns are most convenient when 4 inches deep, 14 inches wide and 22 inches long. These boxes will hold about 200 plants placed about 1 inch apart. As soon as the little plants have formed two or three fronds each, they should be separated and transplanted singly into boxes similarly prepared as before, where they may remain until sufficiently strong to be potted into 2- or 2¼-inch pots.

Times of sowing fern-spores are the first weeks of March, July and October. When making three sowings a year, and allowing a sufficiently longer time for slower-growing varieties, a constant supply of plants will be assured. In calculating on time of sowing spores of commercial varieties of ferns, it will be helpful to divide them into two classes, as some varieties are considerably slower of growth and will consequently have to be sown earlier, in order to be ready for sale at the same time as the more rapid-growing ones. The following popular commercial kinds will require from nine to ten months between times of sowing and potting. The names are those that the plants bear in the trade:

Adiantum cuneatum.
“ “ variegatum.
“ “ grandiceps.
“ Bausei.
“ decorum.
“ Fergusonii.
“ gracillimum.
“ mundulum.
“ tenerum.
“ Wiegandii.
Cibotium Schiedii.
“ regale.
Cyathea medullaris.
Cyrtomium caryotoideum.
“ Fortunei.
“ falcatum.
Davallia tenuifolia stricta.
“ “ Veitchiana.
Dicksonia antarctica.
Doodia aspera.
Doodia aspera multifida.
Doodia caudata.
Doryopteris nobilis.
Lastrea aristata.
“ “ variegata.
“ chrysoloba.
“ opaca.
“ Sieboldii.
Lygodium japonicum.
“ scandens.
Nephrodium hirtipes.
Nephrolepis exaltata.
“ cordata compacta.
Platyloma Bridgesii.
“ falcata.
Polypodium aureum.
“ fraxinifolium, etc.
Polystichum coriaceum.
“ setosum.
Pteris Victoriæ.
“ tremula Smithiana.

The following trade ferns will develop into plants large enough to be potted in about six months after sowing spores:

Adiantum pubescens.
“ hispidulum.
Alsophila australis.
Gymnogramma calomelanos.
“ chrysophylla.
“ decomposita.
“ peruviana.
“ sulphurea.
Lomaria ciliata.
“ gibba.
“ “ platyptera.
Nephrodium immersum cristatum.
Nephrodium molle corymbiferum.
Onychium japonicum.
Pteris argyræa.
Pteris cretica albo-lineata.
“ “ magnifica.
“ “ Mayii.
“ “ nobilis.
“ hastata.
“ “ adiantoides.
“ internata.
“ Sieboldii.
“ leptophylla.
“ Ouvrardii.
“ palmata.
“ serrulata.
“ “ cristata.
“ “ “ nana.
“ tremula.
“ Wimsettii.

It should also be borne in mind, when calculating time of sowing, that spores sown in the autumn will require about four weeks longer for development than those sown at other times of the year.

Fern-spores are borne on the back or under side of fronds. In some cases they are borne naked on under surface of frond, while in others they are produced under a scale-like membrane or indusium. In some cases, as in Pteris, the edge of the pinnæ is folded back over the spores, while in adiantums a small part of the leaflet is folded back over each little fruit-dot to serve as a shield or indusium. Davallias form a small sack-like receptacle at the extremity of the pinnæ. The proper time of gathering spores is when they assume a light brown, rather dry appearance, or in the indusium-bearing kinds when the indusium or shield begins to open. Spores should be gathered on a dark day when the fronds are slightly moist, as they will be better retained in that condition, and will not be so liable to get mixed when disturbed. Fronds, or parts of them, should be cut off entirely in most cases, put up in tight paper bags and stored on shelves in a dry closet for a week, by which time, in most cases, they will be sufficiently dry to have spores removed from them by rubbing the frond in a sieve which has about twenty meshes to the inch. When thus separated from fronds, the spores should be put up in small seed-bags and placed in air-tight jars until required for sowing. Cared for in this manner, perfect success has been invariably secured, even after keeping spores for years.

Propagation by other means.

Some ferns form little plants at the ends of pinnæ and of fronds, which upon attaining to sufficient size may be detached from parent plants, planted into shallow, well-drained seed-pans, and for a week or two left in the propagating-frame, where they will soon form roots, when they can be potted. Among such are *Adiantum caudatum, A. Edgeworthii, A. lunulatum* var. *dolabriforme, Asplenium Belangerii, A. bulbiferum, A. salicifolium, Polystichum angulare* var. *proliferum*, and many more.

A very useful decorative fern is *Nephrolepis davallioides* var. *furcans*, and it will make a beautiful specimen plant in a comparatively short time. To grow large quantities, the old plants should be cut back to within 6 inches of surface of soil and placed in a house where a bottom heat of 90° F. may be secured, when they will soon form a large number of short, strong fronds. At this time they may be divided into a number of small plants, potted off and placed in the same position as the parent plants. A somewhat slower method is to plant out a number of plants on a bench into 5 inches of soil, in which soil the rhizomes, running over the surface, will form a number of small plants, which may be detached and grown on.

A beautiful fern is *Adiantum Farleyense*, and it deservedly ranks as the greatest favorite among fern-lovers. It is best propagated by division. From old plants, cut off all fronds down to the rhizomes, wash off soil, cut rhizomes into pieces ½ inch long, insert same into well-drained fern-boxes about ½ inch apart, in 1½ inches of clean, sharp propagating sand. Place same in propagating-frame in a temperature of 70° F. In this position each little fragment of rhizome will form two or three little fronds in about fifteen or twenty days, when they may be potted off singly into 2-inch pots and kept in a temperature of 70° F. The soil best adapted to *A. Farleyense* is finely chopped sod which has been piled for about six months, with one-fifth well-decomposed cow-manure added. To attain perfection in growth and coloring, *A. Farleyense* should be kept in a light, airy and sunny house, in which every condition of moisture and atmosphere can be kept under absolute control. In a house of this kind, the greatly admired and beautifully pinkish tint may be easily obtained and fronds will be hardy and of good substance. A temperature of 70° F. is at all times desirable.

General culture.

To grow ferns such as are used for jardinières and decorative work and mentioned in the two preceding lists, a temperature of no less than 55° F. should be maintained at all times at night in coldest weather, with a rise of temperature in the daytime of 10° or 15°. To keep ferns in a healthy and growing condition, to prevent and to kill insect pests and diseases, a proper condition of atmosphere should be carefully maintained at all times. Extremes in heat, moisture or dryness should never be allowed. On a warm, dry, sunny day, when a great deal of air has to be admitted, much of the moisture of the house is consequently carried off; it will be of great benefit then to syringe the ferns once or twice a day, also occasionally to dampen floor of houses. An excessively dry atmosphere induces the development of the very troublesome pests, thrips and red spider. On damp and rainy days a saturated atmosphere should be prevented by supplying a little artificial heat, even if some air has to be admitted at the same time. This slight expense of heating on damp days will abundantly pay for itself by causing the growth of strong, thrifty plants. An excessively moist atmosphere causes parts of fronds of a great many plants to turn black and to rot off, besides inducing the development of almost incurable fungoid diseases.

The soil for deep-rooting ferns should be as follows: Three parts fibry loam, one part fibry peat, one part leaf-mold, one part sand, one part sphagnum moss, one-half part broken crocks and one-half part broken charcoal. These ingredients should be thoroughly mixed and ample drainage provided. For shallow-rooting ferns the following compost should be used: One part fibry loam, one part peat, one part leaf-mold, one part sphagnum moss, one-half part broken crock, one part sand, one-half part broken charcoal. If the charcoal cannot be readily secured, half the amount of sand and finely broken crocks will answer, although the composition as prescribed is preferred, as charcoal keeps the soil sweet and may spare time for repotting.

In potting ferns after they pass 4-inch pots, a potting-stick should always be used as the potter cannot very well firm them with his fingers, and it secures eveness in potting. Ferns should be potted tight, especially old plants. Also old plants should be partly shaken out and the roots shortened somewhat, and if carefully handled will quickly reëstablish themselves and make better plants. A potting-stick is very handy also for pressing the compost between rhizomes, and it can be done much more neatly than with the hand.

In the selection and growing of stock plants, the careful grower should always be on the watch for types which are most perfect in shape, in character of individual fronds, in coloring, freedom of producing spores, and exemption from the attacks of insects and fungous diseases. In a large number of ferns a great difference between the different plants of the same species will be apparent to the careful observer. Some plants of same species have beautifully developed fronds, but are carried on long, weak stems, which makes them unfit for general use. Others may be of compact, sturdy habit of growth, but with poorly shaped individual fronds. In some individuals the coloring will be greatly superior. By closely studying all these points and by continually selecting only the most perfect types of ferns from the young plants, one can in a few years work up a very desirable and superior stock. The same stock plants of the rapid-growing varieties of ferns should not be carried over for more than three or four years, but young and more desirable plants should continually be selected and grown to take their places.

The stock should be shifted into larger pots whenever necessary, and placed in a light, airy house, in which all necessary conditions are under perfect control, and in which a temperature in coldest weather of 55° F. at night, with a rise of 10° or 15° in daytime, can always be maintained. The house should be shaded just enough to prevent fronds from turning yellow. Proper attention to atmospheric conditions of stockhouse should never be neglected. Stock plants should not be permitted to remain potbound for too long a period of time, except with a few kinds, such as alsophilas, dicksonias, cyatheas, cibotiums, *Pteris tremula*, *P. argyræa*, some davallias, and *Polystichum coriaceum*, which, if given too much nourishment, will often be very slow in setting spores.

1489. Cyrtomium falcatum. Young plant.

Insects which are most troublesome to ferns are thrips, red spider, scale and mealy-bug. They are mainly present in a too-dry atmosphere. Thrips, red spider and mealy-bug are easily prevented by a properly moistened atmosphere, also by spraying of foliage once a week with tobacco water. As tobacco greatly varies in strength, every grower will have to determine to his own satisfaction how strong to make his solution. The preparation known as "Rose-leaf tobacco extract," has proved very efficient in destroying these insect pests. To fifty gallons of water add one quart of the extract, and apply with some good insecticide sprayer and a force pump. Fifty gallons of this solution will be enough to spray 100,000 ferns in 2¼-inch pots.

Bearing in mind the foregoing advice, the amateur fern-grower may determine the proper way in which to raise his plants. He may not have a fern-house, but he can have a tight glass box or Wardian case. The bottom should be a zinc tray, to prevent drip on the floor and to prevent too rapid drying out of the soil. The top or roof of the box should be hinged, so that it can be raised. In this miniature greenhouse many interesting ferns can be grown. Lycopodiums and selaginellas (which see) are treated in much the same way as ferns.

Nichol N. Bruckner.
X. E. E. Schmitt.†

List of tender ferns. (X. E. E. Schmitt.)

Acrostichum. A widely distributed class of ferns found in tropics of both hemispheres; some have fronds that are solitary, while others are pinnatifid; some are deep-rooting and require a loamier soil, while others are shallow-rooting and require a very shallow and porous soil. They are a class varied in many respects; the fertile fronds are totally covered on the under side with the spores, generally brown in color, and when ripe, after shedding the spores, will perish and be succeeded by the barren fronds. Propagated by division and spores. Winter 55° to 60° night. They should have a perfect drainage, the deep-rooting ones of ordinary depth, but the shallow-rooting are best grown in a depth of about 2 inches of soil and very porous, as for davallias, the shallow-rooting species; they all love a moist and shady atmosphere except *A. aureum*, which will stand sun with its roots in 2 inches of water; it is found in Florida and tropical America.

Actinopteris. A low-growing and charming class of ferns with palm-like or rayed fronds. They thrive best in a compost of loam, peat, chopped sphagnum moss, coarse sand and crocks (broken small), in equal parts; they should have ample drainage, filling the pots about half-full with crocks. They require a good light and plenty of moisture; they are best propagated by spores; they can also be divided. Winter temperature, 58° to 60°.

Adiantum. The maidenhair ferns with fronds, the individual pinnæ of which vary from not more than ⅛ inch in width in *A. gracillimum* to the large *A. peruvianum* with pinnæ 2½ to 3 inches long. They are hardy, stove and temperate ferns, and require a deep rich soil and plenty of water during the growing season, and less during the resting-period, which is usually from December to the latter part of February. They should be allowed to get fairly dry but not wilted before they are watered again. In most species or varieties of garden origin, remove part of the old fronds just as growth commences; with some of the denser-growing sorts, all the fronds may be cut away just as the new growth is commencing, as it is very tedious and there is not much gained thereby. It should be cut close, but with sparser or large-growing sorts as *A. trapeziforme* and many other strong-foliaged sorts, it is better to leave all the good foliage possible to stimulate the new growth; turn the plants out of the pot, cut away the lower half of the ball and trim in the sides of the old ball close to the rhizomes with a large knife, then loosen slightly the edge of the ball with a sharp-pointed stick so that the roots will feel the effect of the new move readily; never round off the sides in a slant or sloping manner as the old crowns are very closely knit together and trouble would be experienced in getting them wet through again. Should they become too dry, give a little water every few minutes until they are given enough to penetrate the old ball. The crowns should be let down a little deeper than they were when turned out of the pot. The surface should be slightly pointed here and there which will help the water more readily to penetrate. Have the pots well drained, placing a thin layer of sphagnum moss over the crocks which will keep the drainage clean. Fill in the soil, pack firmly with a potting stick up to the height required to receive the ball, which should be low enough to give a light covering of soil; they throw out their new roots from top, bottom and sides; then place in a layer of soil, tightening it with the potting stick, place layer after tightening as before until it has reached the required height; give a fair watering, fill about twice the space left from the top of the soil to the rim of the pot. They will not require any water for two or three days, then give a light sprinkling with a watering-pot with a rose on. They will require to be looked over every other day or so. In about a week's time they will require a moderate watering, but not so heavy as at first. After potting, an increase of 8° to 10° in temperature, both by night and by day, is necessary. Some of the smaller-growing sorts will require a deeper drainage and smaller pots. Adiantums with a few exceptions will not tolerate syringing at any time, particularly during dull or cloudy weather, as damp may settle in the foliage and ruin several plants, but care must be taken that they have sufficient water at the roots, as in the growing season they take a good supply of water. The temperature in winter for greenhouse ferns should be 52° by night, adding 6° to 8° by day; stove should be 56° to 58° by night, adding about 6° by day. Adiantums require a mixture of chopped or hand-broken fibry sod that has been stacked about six months, one-half part peat, one-half part leaf-mold, one part well-decayed cow-manure preferred (as they are good feeders), one and one-half part sand, one part chopped sphagnum, one-half part broken crocks and one-half broken charcoal about ¾ inch in size, using fine and all; place in even layers in the order above stated, then turn three or four times which will leave the whole evenly mixed, when it will be ready for use. For cult. of *A. Farleyense*, see p. 1212.

Alsophila. Tree ferns, natives of tropical America and Australia. *A. australis* and *A. excelsa* will stand sun with a copious supply of water. Soil as for Dicksonia. Winter temperature for Australian species, 50° to 55°; for West Indian, 58° to 60° night.

Anemia. A pretty class of small-growing ferns, sometimes called the flowering ferns, as the fertile sprays appear along with the sterile frond. They require an open porous soil and are not deep-rooted. Moderate temperature, 52° to 55° winter temperature by night. Propagated by spores.

Angiopteris. Giant ferns, more resembling a cycad than a fern, were it not for the spore cases. They are native of tropical Africa, tropical Asia and the Philippines. They are deep-rooting, with heavy and fleshy roots, and enjoy a rich deep and porous soil. They require a high and moist temperature, not less than 60° by night in winter and will stand 90° or more in summer. They require shade during summer, with more light during winter. A soil as for dicksonias, with the addition of a little manure is satisfactory. They should be potted just as growth is commencing. Care should be taken not to bruise their fleshy roots; should any be damaged they should be cut off with a sharp knife. Propagated by spores and division, both a slow process, but more readily by the large and fleshy scales carefully removed from the old plants, laid between sphagnum moss, sand and broken crocks in a case with a bottom heat of 80° or a little more; they should be laid on a slant with inner side of scale facing upward. When they have formed buds, emitted roots, and made two or three leaves, they may be detached and potted singly in as small pots as their roots will permit; return to case and inure to more light and air gradually; each scale may bring four or five plants.

Blechnum. Ferns of easy culture, requiring moderate shade. Allied to Lomaria. Several of them are dwarf tree ferns; others have spreading rootstock. They will not stand dryness; require a moderately strong soil containing a small amount of manure.

Cheilanthes. A class of dainty and graceful ferns. They require an open and porous soil; will not tolerate syringing, and require a good light at all times. Propagated by spores and division, spores preferred. They will not stand an overabundance of moisture at any time, but will well repay proper care, as they are all very beautiful. Some have fronds resembling the palmate fronds of Doryopteris, while others are very much divided. The soil should consist of one part fibry loam, one part peat, one part leaf-mold, one part sand, one-half part broken crocks, one part sphagnum moss and one-half part broken charcoal, broken quite small, the whole thoroughly mixed together and the pots well drained. A temperature of 50° to 55° suits them best in winter.

Cyathea. Beautiful tree ferns, native of New Zealand and tropical America. *C. medullaris* will grow to a great height, from 60 to 75 feet, and is often seen in its wild state far above the surrounding vegetation. Will stand full sun. Temperature for New Zealand species, 50° to 55° winter; tropical American, 55° to 60° nights. Soil as for Dicksonia.

Cyrtomium. Fig. 1489. Ferns of easy culture. Require a greenhouse temperature of 48° to 50° by night in winter; will stand a strong light and partial shade. Useful for fern-dishes. Allied to Aspidium. General culture for ferns.

Davallia is a beautiful class of ferns found both in the tropical and subtropical zones. The smaller-growing forms can be grown in shallow baskets or pans and have a fair amount of rest in winter. The Japanese fern-balls are probably *D. bullata* and *D. Mariesii*, and can be laid out in the garden and frozen down to zero and when the growing season returns watered and they will begin to grow again. Davallias with heavy rhizomes or any of the surface creeping sorts will want to be kept a little on the dry side during the resting period, which is from the beginning of December to about March, when they will gradually recommence, and water should be given accordingly. They must be syringed at least twice daily in winter, as black thrip is liable to attack them; should they be attacked, dip in a medium solution of aphine or fresh tobacco water. Should the plants be too large to handle, syringe them with aphine or tobacco water at night and give a thorough syringing with clear water the next day; apply two or three times, then stop for two or three days, then repeat, after which the troubles will be over. The cooler kinds will commence their growth about a month later than stove kinds. They should be repotted or top-dressed just as growth commences, if they require it.

D. pallida is a fern which rests from December to March, at which time gradual increase of water may be given it and by the end of March it will be commencing its growth. It should be carefully separated, taking care not to injure the points of the rhizomes. Many of them will be found all the way to the bottom of the pots or pans in which they have been growing. It is well to leave an old specimen undisturbed for three or four years and only give a light top-dressing in the spring as growth is commencing, and weak liquid manure about every two weeks as the fronds are unfolding; but always water with clear water first, then follow with liquid manure. It requires a stove temperature of 58° to 68° by night, adding 6° to 8° by day on bright days, during its resting period, with corresponding increase during the growing season of about 20°. It needs a good strong light but also shade. It requires a good supply of water during its growing season and only a small amount once a week, but must be syringed twice daily. The composition of the soil should be an open and porous material consisting of the following: two parts fibry loam which had been stacked about six months and broken up by hand (not sifted or pulverized), one part fibry chopped peat, one part leaf-mold, one part sand, one-half part broken charcoal, using in the same manner as the crocks, one part sphagnum moss chopped roughly, all the parts of this composition placed in even layers in the order named four times, first to the left, then to the right, when it will be of the proper texture ready for use. The pots or pans should be well drained by placing a flat piece of crock over the holes flat side down. The soil should be hand-picked so as to be free of worms and insects. This process is slow and tedious, but when there is taken into consideration the length of time a plant is to remain undisturbed, too much care cannot be taken. Place the curved pieces one against the other until the entire bottom is covered, then place a good sprinkling of clean ¾ inch soil (no dust), and cover the whole with a thin layer of sphagnum moss, covering the crocks evenly so that no soil will pass through. The receptacle is now ready for the soil. Place some of the roughest of the soil directly over the moss, then filling up to within 2 inches of the top, pack down evenly with a wide potting stick so that they will not sink afterward; now put in the rhizomes one by one, setting the points so that they will be evenly distributed, and firm the soil tightly with the fingers, as a potting stick cannot well be used on account of bruising; let them be about even with the top on the sides and slightly rounded in the center; stake the fronds with light stakes to keep them steady, which will give them a neat appearance as they will have to remain until the new growth has developed and the plant is reëstablished with new roots, when they will sustain themselves without any supports. The plant is now ready for watering; one even watering is all that will be required and a light syringing four times a day. Should the surface become dryish a light watering should be given as when first potted, but after this the plants will require water more frequently as they will be making roots rapidly as will be indicated by the foliage that has developed. Directly after potting keep the house close and increase the air gradually until full air can be given. Hard-leaved ferns like davallias can stand a light syringing three or four times a day on all bright days but none on cloudy days unless there is artificial heat on. Decrease syringing as the cool nights of the end of summer and autumn approach; the temperature may also be lowered until it falls to the winter temperature with the declining season. The foregoing soil is suitable for most shallow-rooting ferns.

Dennstædtia. With creeping rootstock. Winter temperature, 52° to 55°. Propagated by spores and division. Culture as for Microlepia.

Deparia. A small group of ferns with arching fronds. Stove winter temperature, 55° to 58°. Propagated by spores or bulbils that form on the fronds. Culture, see main article (p. 1210).

Dicksonia. An interesting class of tree ferns from Australia. They require a cool temperature and partial shade in summer, but their stems must be syringed frequently. They must never be allowed to dry at the roots, and even more copiously watered in summer. Winter temperature, 45° to 48°; can be stood outside in summer. Can be propagated by spores or side growths carefully removed from the parent stem without injuring the heel. Require a soil of three parts loam, one part peat, one part leaf-mold, a little more than one part sand, some broken crocks and sphagnum moss with the whole, and well drained.

Didymochlæna. An interesting group of ferns of distinct habit and growth. Winter temperature, 55° to 58°.

Diplazium. A rather coarse-growing but interesting class of ferns, grown mostly in the greenhouse. Allied to Asplenium. A fairly porous soil suits them best. Propagated by spores or division. Winter temperature, 55° to 60.°

Doodia. A small and distinct class of ferns of cool temperature, 48° to 52°. Propagated by spores and division. For culture, see main article (p. 1210)

Drynaria. Plants with a thick and downy rhizome. Propagated by spores and division. All stove ferns allied to Polypodium.

Dryopteris. Small stove ferns. Require a winter night temperature of 55° to 58°.

Gleichenia. A genus of most beautiful and graceful ferns, natives of Australia, New Holland and tropical America. They thrive best in a compost of one part loam, one part peat, one-half part sand, one-half part broken crocks, one part sphagnum moss; in potting, the center of the plant should be dropped a little below the rim of the pot so that the outer rhizomes can rest on the new soil, leaving the center a little deeper than the outer edge; pin the rhizomes down carefully but do not cover; pot firmly; give a gentle watering; syringe several times a day, but take care not to overwater. They love a cool, moist atmosphere; the tropical American ones can stand a little more heat, also a little sun; winter temperature for New Holland ones, 48° to 52°; American, 50° to 55°. Care should be taken at all times not to overwater or let them get too dry; the best way is to sound them with your knuckles, and in fact almost any plant of careful treatment should be treated the same way.

Goniophlebium. Mostly a deep and free-rooting class of ferns, demanding culture as for Polypodium.

Hemionitis. An interesting class of low-growing stove ferns requiring a porous soil. Winter temperature, 55° to 58°. Propagated by spores, or by pinning a mature frond having formed buds, on a surface of porous sandy material, which readily form new plants.

Hemitelia. A distinct and striking class of tree ferns, native of tropical America and the Philippines. They are all stove ferns requiring 60° winter night temperature and ample moisture and shade at all times; soil as for Dicksonia, as they are heavy and deep-rooting.

Hymenophyllum. A class of ferns of most graceful and delicate structure; native of tropical America. They require a deep shade and a shallow compost to grow in as they are found growing on tree ferns and sandstone; the following will suit them best: sandy, lumpy peat with very small pieces of sandstone and live sphagnum moss, carefully placed between the small rhizomes and grown in a dense shade. Their foliage should never be allowed to become dry; they should be grown in a case. Winter temperature, 52° to 55°.

Hypolepis. A class of ferns with creeping rootstock, of easy culture, requiring shade. Propagated by spores and division. General culture of ferns.

Leucostegia. A class of ferns allied to Microlepia and Davallia, which see. Deep-rooting ferns of easy culture. Winter temperature, 52° to 55°.

Lygodium. A class of ferns of easy culture, requiring a deep rich loamy soil. *L. palmatum* is hardy. For culture, see main article (p. 1210).

Marattia. A bold, distinct, and interesting class of ferns. Allied to Angiopteris, which see for treatment.

Meniscium. A small class of interesting low-growing ferns. Require a medium temperature of 52° to 55° in winter. General culture of ferns (p. 1210). Propagated by spores.

Microlepia. A class of mostly strong-growing and graceful ferns of easy culture; *M. hirta* var. *cristata*, being crested, makes a beautiful specimen. They like a strong open soil with a little cow-manure added and a fair supply of water at all times. They require good light but shady. Propagated by division or spores.

1490. Pteris cretica var. albo-lineata. (× ½)

Nephrolepis. A large group of ferns having more garden forms than any other class of ferns, and the end is not yet in sight, as every year or two another form appears; the type *N. exaltata* will grow fronds 4 to 5 feet long, while some of the variations will grow them as short as 8 inches long. All the forms of *N. exaltata* will stand sunshine under glass. A compost of three parts good fibry loam, one part manure, one part sand, a small sprinkling of leaf-mold and sphagnum moss thoroughly mixed, suits them best. They like a fair supply of water at all times. When potting, always drop the plant down so as to cover ¼ inch, as the young fronds will readily push through the soil. *N. Bausei* is deciduous. *N. Duffii* is a small fronded and beautiful species. Propagated readily by runners, of which they furnish an abundance; pin the runners down over the surface of the soil; in a short time they will make a lot of young plants which can be taken up when they have made two fronds, potted up into 2-inch pots, kept close for about two weeks, when more air can be given them; then pot on as required.

Notholæna sinuata. Native of Mexico; an interesting and graceful fern of downy foliage. Grows well in a medium temperature. Care must be taken in watering; it will not stand syringing. An open porous soil suits it best. Propagated by division or spores, spores preferred.

Onychium. A class of interesting and graceful ferns of easy culture for which see main article. Winter temperature 48° to 52°. Propagated by spores or division.

Pellæa. A very interesting class of low-growing ferns of neat and graceful habit. Winter temperature 55° to 58° at night. Requires a porous soil and good light; will not stand very much moisture on foliage. Thrip and mealy-bug are the worst enemies. Readily propagated by spores or division.

Phlebodium. Ferns of strong-growing habit. See *Polypodium.*

Phyllitis. A class of shallow-rooting ferns of easy culture. Allied to Polypodium, which see.

Phymatodes Somewhat shallow-rooted, but fairly strong-growing ferns, of easy culture. Best grown in pans. Require partial shade and a porous soil as for shallow polypodiums or davallias. They may also be used to cover walls in greenhouses, and to grow on trunks of tall tree ferns.

Platycerium. The stag and elk's-horn ferns. A distinct and most interesting class of ferns. They naturally grow in the forks of trees and on rocks. They are best grown on blocks or rafts; fibry peat and live sphagnum moss suit them best. They should have plenty of water in the growing season and a moist atmosphere at all times. Winter temperature at night, 58° to 60°, adding 5° to 7° by day.

Polypodium. Comprising many divisions and many of them in common cultivation. They are native of all climes. Some are hardy with hardly any protection, while some require stove temperature. Some are deep-rooting, while others are very shallow-rooting and require a very porous soil. They are mostly evergreen excepting the hardy species, which are deciduous. Some of the shallow-rooting species will grow on a surface of very shallow material composed of peat and moss, while others require an addition of loam. They are varied and distinct and can be employed for many purposes, to cover walls in a greenhouse or conservatory or rockwork out-of-doors. Some are very decorative and bold in habit, while others are graceful and beautiful. The deep-rooting kinds require a compost of two parts loam, one part leaf-mold, one part peat, one part sand, one part sphagnum moss, one-half part broken crocks and one-half part broken charcoal; they require ample drainage and an ample supply of water when growing, and reduced amount when at rest in winter. The shallow-growing sorts will require ample drainage and a compost of one part fibry loam, one part peat, one part sphagnum moss, one-half part broken crocks and one-half part charcoal. Some of the sorts will grow on a mossy surface or can be employed to cover walls or unsightly places in a greenhouse and by receiving an occasional syringing will do well, while others are better grown in pots or pans. Pans for many are preferred.

Polystichum. Many of these are hardy or will winter out-of-doors with moderate protection. Propagated by spores or by pinning down the fronds on a porous surface until small buds are fairly well rooted, when they may be detached and potted singly. A moderate soil suits them best.

Pteris. Fig. 1490. A various group, some of them hardy, others suitable for greenhouses and for stoves. They are not particular as to soil; a mixture of two parts peat, one part loam and one part sand will suit them. The variegated forms should be protected from very strong light. Some of the species propagate readily by division of the creeping rhizomes. Most of the tender species thrive in an intermediate or greenhouse temperature.

Selaginella. A class of plants of decorative and useful character and varied in form of growth as *S. cæsia*, *S. arborea* and *S. Willdenovii;* will grow to 15 or more feet, while others will not rise over 2 inches or so. Propagated by cuttings in the larger-growing kinds, division in most kinds, and pegging in some tall-growing species. Take down a tall-growing sort and peg it to mossy and sandy surface and in a short time when fairly well rooted, it may be potted separately in the regular mixture for Selaginella. Compost for Selaginella, two parts loam, one part fibry peat, one part leaf-mold, one part sand, one part sphagnum moss, one-half part broken crocks and one part charcoal. Mix the whole thoroughly, drain well as recommended for ferns. *S. grandis* and *S. Lyallii* require a Wardian case and will need a very moist atmosphere at all times, also a temperature of 60° by night, with corresponding increase by day in winter; in summer, 80° to 90° by day.

Todea. The filmy ferns of New Zealand are *T. superba*, the finest of them all; they are rare and seldom met with; they love a deep shade and coolness at all times; a temperature of 40° to 45° in winter suits them best. Their fronds should never be allowed to become dry. The strong-fronded ferns are stove ferns, requiring a winter temperature of 55° to 60°.

Trichomanes. A class of filmy ferns of great beauty, requiring a cool and moist atmosphere. They should be grown in fibry peat, sphagnum moss, sand, and broken crocks in equal parts. They are very shallow-rooting and must be handled with the utmost care in repotting. They must be potted tight, and if small broken sandstone can be had, all the better; the depth of the soil need not be more than 1 to 1½ inches. Temperature 45° to 50° in winter. They should be grown in a Wardian case, kept close except an opening on the coolest side. The fronds should never become dry; but should be sprayed several times a day if there is danger of their becoming dry.

Vittaria lineata. A very unusual fern growing naturally on trees in southern Florida. It does best fastened on a block in a mixture of fibry peat and sphagnum moss or in shallow baskets in the foregoing materials with a portion of sand, broken crocks and charcoal broken small. Pot firmly but let the material be shallow. It loves plenty of water at all times and a good light. Propagated by division and spores. Winter temperature 55° by night.

Cultivation of hardy ferns.

The hardy ferns are easy to transplant and tenacious of life under adverse conditions, but since the beauty of fern foliage is brought out only by luxuriance of growth, it should be the aim to plant only where such can be secured.

Ferns in general require positions in which the soil retains an even amount of moisture at all times. Most species do not grow well in a cultivated border or where the space between the plants is not mulched or given a ground cover of mosses or other plants which hold the temperature and moisture of the soil surface more evenly and allow the ferns to grow roots near and on the surface of the ground. Also when the earth is bare between the plants, the rains dash mud on the under side of the fronds—a condition under which no fern can thrive. However, some of the stronger-growing species, as the osmundas, because of their height and strong deep roots will do well in a cultivated border. A study of the soil surface where the fern is growing well in the wild will show about what is necessary.

Some ferns, as the maidenhair (Adiantum), have strong wiry stems which will push up through a very heavy covering of leaves, while other species, as all of the evergreen ferns, grow in positions in which the annual fall of leaves does not remain on their fronds. The larger number of ferns prefer no heavier mulch than is made by the death of their own fronds, which naturally fall away from the center of the plant, mulch the surrounding soil but leave the crown of the plant uncovered and unhindered for its growth in the spring. Many of the smaller ferns which have neither deep nor strong creeping roots require a ground cover of other plants or simulated conditions to prevent their being heaved out of the ground during the winter. A number of species with strong creeping roots as *Dennstædtia punctilobula* (*Dicksonia pilosiuscula*) and *Dryopteris* (*Aspidium*) *novaboracensis* eventually form thick masses which completely cover and fill the ground with roots. When this condition has been attained, no soil mulch or cover is needed, and even the old fronds had best be removed before growth starts in the spring.

Ferns may be separated into two classes by their stems: (1) those with creeping stems, and (2) those having a central crown or cluster of crowns.

Those with creeping stems spread and form large masses. They not only send up a crop of fronds in the spring but continue to grow new fronds during the season. This class of ferns may be transplanted at any season with ordinary care, in fact the fronds may be mowed off and the roots taken up in sods and relaid like turf, but better results will be secured with more care to preserve the younger and newly started fronds.

Those ferns with distinct crowns naturally send out only one set of fronds each year. This class of ferns is best moved after the plants have ceased growth in the fall or before growth starts in the spring. Especially is this the case with those species having deciduous or fragile fronds which easily become wilted or broken. When transplanting while in leaf, it is necessary to preserve fully half of the fronds to insure a good growth the following year. The evergreen species, as the Christmas fern (*Polystichum* or *Aspidium acrostichoides*), *Dryopteris* (*Aspidium*) *marginalis* and others with hard coriaceous foliage, can with reasonable care be transplanted at any season of the year.

In general, the soil for ferns should be rich in humus and mineral matter and sufficiently friable to allow penetration by the fine roots. A heavy clay is not satisfactory but may be corrected by the addition of a sandy soil and thoroughly rotted manure or leaves. A pure leaf-mold is not a good fern soil because it is lacking in minerals and is too light and loose for any fern except the Adiantum. A good sandy loam with too little clay to bake and not enough vegetable matter to be spongy will suit the larger part of ferns. It will be noticed that most species of ferns with crowns grow in the wild where their roots reach through the surface mold to a more mineral soil underneath; in fact they often grow in apparently poor yellow loam.

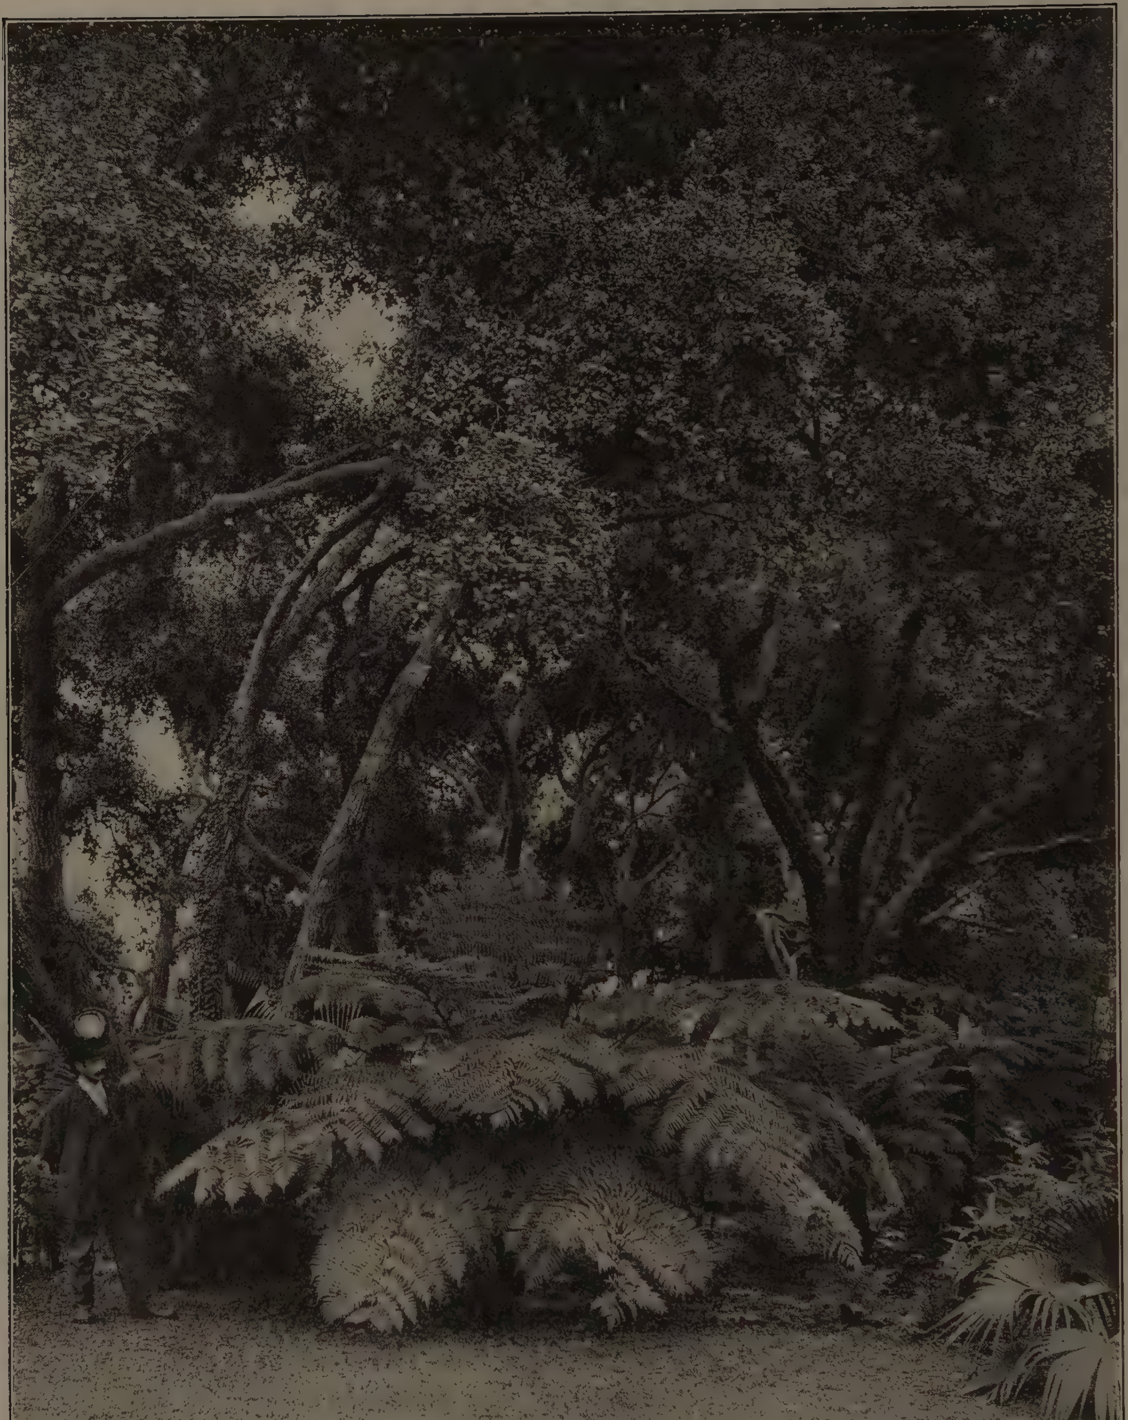
The following ferns grow luxuriantly in full sunlight with suitable conditions of soil and moisture: *Pteris aquilina*, *Onoclea sensibilis*, *Dennstædtia punctilobula* (*Dicksonia pilosiuscula*), *Dryopteris* (*Aspidium*) *novaboracensis*, and the osmundas.

Practically all the remaining species prefer more or less protection from the direct rays of the sun, but darkness or dense shadow is not required. Even the species which grow in deep, dense shade apparently need only the humid atmosphere found there, since near waterfalls and springs they grow in the open. In mountainous regions in which the atmosphere is cool and not drying, many species grow in full sunlight which require more or less shade in drier climates. Among such might be mentioned *Asplenium Filix-fœmina*, *A. acrostichoides*, *Phegopteris hexagonoptera*, *P. polypodioides*, *Dryopteris* (*Aspidium*) *Thelypteris*, *D. cristata*, *Onoclea Struthiopteris*, *Woodwardia virginica*, and *W. angustifolia*.

1491. Dryopteris simulata.

There are about seventy-five native American species which can be grown in northern gardens, and also a good number of quite distinct varieties. There are hardy species in foreign countries so that a complete collection of hardy ferns would probably reach 150 species.

The following species not natives of the United States are hardy at Philadelphia: *Dryopteris chrysoloba*, *D.*



XLI. A good fern in southern California.—Alsophila australis.

dilatata, D. Filix-mas, D. pseudo-mas Pinderi, Nephrodium hirtipes, Polystichum Braunii, P. lobatum and *P. setosum.*

The following notes are drawn from experience in cultivation of these native ferns in the neighborhood of Philadelphia.

Adiantum pedatum prefers light, loose, rich soil in cool, moist shade, with yearly mulch of leaves. Soil conditions are more important than shade. Where established in a wild state will endure the full sunshine coming with the removal of trees until soil conditions change or it is crowded out by stronger plants.

Adiantum Capillus-Veneris. Soil conditions about the same. See that leaf-covering is not of too large and heavy leaves.

Asplenium acrostichoides. Culture as A. Filix-fœmina.

Asplenium angustifolium thrives on rich rather moist soil in shade. Avoid complete removal of fronds when planting in early fall, as this fern quickly sends up new fronds to the weakening of the following season's growth.

Asplenium Bradleyi. A small rare fern. See Camptosorus and A. pinnatifidum for cultivation.

Asplenium ebenoides. Culture same as for A. pinnatifidum or Camptosorus.

Asplenium Filix-fœmina. Give good rich loam, moist, with drainage, with some shade. Endures full sunlight in cool climate. A beautiful and extremely variable fern. A number of forms are catalogued.

Asplenium montanum. Cultivated as Camptosorus or A. pinnatifidum.

Asplenium pinnatifidum. A small evergreen fern found in the wild in cool shaded places in which there is an uniform amount of moisture in the soil and when the air is not given to quick extremes of temperature and humidity. Ferns of this character need about the same careful placing as do real alpine plants. Planting between stones is advisable. No winter cover, no bare soil and no plant stronger-rooted than a moss near it.

Asplenium platyneuron prefers partial shade. Care must be taken to prevent smothering by leaves, and to plant where the least likely to be heaved by frost. It is found most plentifully as a native on banks growing with grass and other plants in partial shade. The fronds are evergreen, but become discolored in severe weather. Any good loam suits it. Easy to move at any season but difficult to maintain in masses.

Asplenium resiliens (A. parvulum). Culture of A. platyneuron,

Asplenium Ruta-muraria. Culture same as A. pinnatifidum.

Asplenium Trichomanes. A small fern growing well where A. platyneuron does. The shade of a small rock will suit it.

Asplenium viride. See A. pinnatifidum for culture.

Camptosorus rhizophyllus. WALKING-LEAF FERN. In wild state is found in cool, shaded positions not subject to excessive drought or moisture. It prefers a moist atmosphere but this is not necessary for good growth but where the best soil and atmospheric conditions prevail the leaves often attain a length of 18 inches before rooting. Avoid all winter covering.

Cheilanthes. Low-growing rock ferns generally doing well in fairly dry positions. *C. lanosa* prefers deep shade and more moist soil. *C. lanosa, C. tomentosa* and *C. Fendleri* at least of the species are perfectly hardy at Philadelphia.

Cryptogramma acrostichoides should have shade throughout year.

Cystopteris bulbifera. Will do well in usual deciduous shade in any loam, but grows best and produces far more numerous bulblets when planted on a moist bank of gravelly soil in the shade of kalmia.

Cystopteris fragilis should be planted in shade in positions where it will receive no covering of leaves. The fronds die in early August in the drier situations. It will grow in positions which become exceedingly dry in midsummer. It forces well in a coolhouse.

Dennstædtia punctilobula (Dicksonia pilosiuscula) prefers shady, moist situations where it does not receive any covering by falling leaves of large size. Grows well in sunshine. May be transplanted at any season, and takes kindly to heavy enrichment. The best fern to grow in quantity for cutting during the summer. Can be readily grown as a north border to a shrubbery in any medium to light loam.

Dryopteris Bootti is found in a wild state in moist, shaded positions, but will grow well in shade in quite dry positions. Does not need shade in winter. Use good loam.

Dryopteris cristata prefers moist to wet soil in shade. Will often burn with direct sunlight. Evergreen, quite variable. Var. *Clintoniana* is larger. The fern and variety appear to need swamp conditions to grow well.

Dryopteris Filix-mas. Practically the same conditions as for D. marginalis.

Dryopteris Goldieana prefers deep, moist, rich soil in cool shade. Grows finely in shaded places and soil suited to rhododendrons.

Dryopteris marginalis wants rich soil in rather deep shade during the entire year, but will grow well in partial shade—and endure even full sunlight, though not growing so luxuriantly. This is one of the native ferns commonly sold by collectors in city markets. It is evidently seldom established by purchasers of plants in full leaf. Once wilted the plants will not recover.

Dryopteris noveboracensis does best in rather moist, rich soil in partial shade, but will endure full sunlight with good soil conditions. Prefers light rich loam. One of the common field ferns growing in large masses either alone or with Dennstædtia punctilobula. When cut it wilts quickly so is of little value for bouquets. Easily transplanted at any season. Will not endure heavy mulch of leaves. Not evergreen.

Dryopteris spinulosa is less common in America than the var. *intermedia*, which occurs wherever conditions favor its growth. It has the finest cut or divided fronds of any of the large evergreen ferns, being almost the equal of the deciduous fern, Dennstædtia punctilobula, in this respect. The fronds are gathered extensively for florists' use. In culture, give the same conditions as for Polystichum acrostichoides, with heavier shade and more moisture. The best fern to grow under coniferous trees.

Dryopteris simulata (Fig. 1491) is much like the following and requires similar conditions. It occurs in boggy woods from Maine to Maryland and perhaps westward.

Dryopteris Thelypteris prefers quite moist situations with at least partial shade. With congenial soil and moisture does well in sunlight. A distinct and pleasing deciduous fern.

Lygodium palmatum is rather difficult to establish. Give a deep rather moist light loam in partial shade.

Onoclea sensibilis prefers a rich, moist soil in partial shade or full sunshine. It will also grow in shade. It likes a heavier soil than most ferns and uniform moisture. Does poorly in dry soils.

Onoclea Struthiopteris should be given a rich, moist soil with at least partial shade. The fronds will "burn" in fierce sunlight. A good fern to grow north of a wall or building where specimen plants are desired.

Osmunda cinnamomea prefers moist, partially shaded situations, but will grow well in full sunshine in rich soil not exceedingly dry. Perhaps the most beautiful of the osmundas. Best to move while dormant.

Osmunda Claytoniana, a native of low ground, both in shade and sunshine, but will grow equally well in rich soil only fairly moist. Best transplanted when dormant.

Osmunda regalis prefers a peaty soil in very wet, boggy position in partial shade, but will grow as well in full sunshine if soil is rich and not dry. A very distinct fern.

Pellæa atropurpurea prefers rather dry positions in partial shade, winter and summer. It will not endure heavy mulching. Will grow in full sunshine, but not to its full size. It may be transplanted at any season.

Phegopteris Dryopteris prefers good soil in shade not over moist or dry. Avoid coating of leaves. It is a beautiful species and useful for planting on rockwork in shade. The fronds die in August.

Phegopteris hexagonoptera needs good soil in shade. Fronds die down rather early. Will not grow well through a leaf mulch.

Phegopteris polypodioides prefers moist, shaded positions, but will grow in any good soil not too dry. The fronds die down in late summer, especially in the drier positions. Any winter covering of leaves must be removed.

Polypodium vulgare prefers good, light soil in well-drained but moist situations in shade, with no other plants growing with it. It will endure very dry places, but will be dwarfed. Will also do well in full sunlight if soil conditions are good. As a native it grows in positions in which it does not receive any yearly coating of fallen leaves, and, wherever planted, should not be covered with coarse material. Plant perfectly evergreen; height 6 to 10 inches.

Polypodium incanum of Virginia and the South is hardy but not vigorous at Philadelphia.

Polystichum Braunii. This fern needs good deep light loam, not spongy, with humus and shade winter and summer. A distinct and beautiful evergreen fern open to improvement by selection and culture, although belonging to the class of "crown" or "tree" ferns which do not have the chance to vary or "sport" which the species with vegetative roots do.

Polystichum (Aspidium) acrostichoides should be given shade both summer and winter for best results, and in no case can shade in summer be omitted. The plants will endure sunshine for a few years but will not be thrifty, and will eventually die. One of the more common florists' ferns—the Christmas fern—the sterile fronds of which are gathered and stored by the million for winter use by florists. They are found on the north side of the hills and the best grade grows not in low ground nor where the soil is shallow but where good loam with no winter leaf covering are the conditions. The planting of this fern for the sale of the fronds may become profitable as demands increase and its wild habitats become forbidden grounds to pickers. In culture give (1) northern exposure; (2) good corn land; (3) no loose or bare earth between plants; (4) no grass; (5) no real cover of leaves in the fall. Give with these a good supply of moisture such as the lower half of a hillside can easily be made to receive from the overflow from rainfall on the upper half. There must be good drainage.

Polystichum fragrans. Positions in the wild suggest dense cool moist shade with good drainage.

Polystichum Lonchitis. Grows well under conditions for P. acrostichoides as far south as Philadelphia.

Pteridium aquilinum, to be grown to perfection, should have considerable sunlight, with moist, rich soil, kept cool and loose with a coating of leaves or other material. In such a position it should grow to 4 to 5 feet high, with other dimensions corresponding. However, it will grow in almost any position. It has strong, creeping rootstocks, so that attention is necessary to keep a healthy group within bounds. The earliest fronds put forth die in late summer, but those of later growth remain green until frost, so that with attention to the removal of dead fronds a group will look well until fall. The rootstocks break or crack easily so that plants are injured by transplanting and grow poorly until again established. Early spring is the best time to move plants.

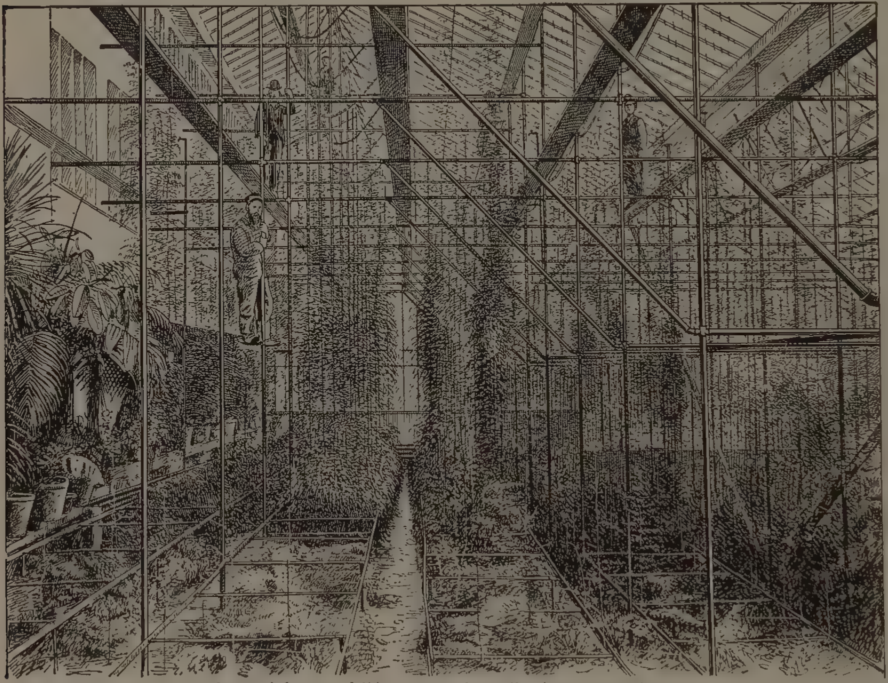
Woodsia. Small rock ferns mostly requiring winter shade and doing best on rock banks facing the north.

Woodwardia angustifolia wants a moist situation in deep shade. Does well in moist peat north of a bank or wall. Will endure full sunlight in positions where it has become established, but will not grow well when transplanted to sunny position. *W. virginica* needs more moisture.

F. W. Barclay.

Culture of asparagus fern (Fig. 1492).

The sprays of *Asparagus plumosus* look so much like certain ferns or selaginellas, that the plant is commonly known as asparagus fern; and the cultivation of it is therefore treated at this place. (For the botanical account, see p. 407, Vol. I.) The first and all-important factor in the cultivation of asparagus fern is the construction of the bed. To meet with any degree of success, the bed must have perfect drainage. The house should be 25 or 30 feet high, and wired at the top and bottom. The wires beneath are made fast to each side of an iron trellis about 8 inches apart and at the top an equal distance apart, in order that the strings may be as nearly straight as possible.



1492. A house of "Asparagus ferns."—Asparagus plumosus.

The early growth of *Asparagus plumosus* var. *nanus* is very slow; but as soon as it is transplanted and well rooted in a rich soil, the growth is more rapid, the tender shoots developing into a vine which will be ready to cut for the market in about a year. There is great difficulty in securing the seed of the nanus. In a whole house, there may be only a few seed-bearing strings. After being picked, the berries are allowed to dry for a month, and are then ready for planting. A good, rich soil, covered with a thin film of sand, serves very well to start them. The temperature should be about 65°, and as nearly constant as possible. When the plant is well rooted, it is removed to a deeper soil or potted in 3- or 4-inch pots and placed on a bench. Here it remains a year, and is then placed in the bed.

Up to this time a small amount of labor suffices to keep the plant growing in a healthy condition; but from now on great care must be taken and much labor expended to produce the best crop. The bed into which the young plant is set should be carefully laid with rocks at the bottom, so the water can escape freely. Over this place 2 or 3 feet of soil, manure, and dead leaves. It is but a short time now that the roots have room to expand before the shoots appear above the trellis, and the stringing begins. Strong linen thread is used for strings.

The first crop will not be ready to cut before the end of the second year,—that is, from the time the seed is planted. As soon as this crop is exhausted, new strings are put in place of the old, and another crop is started. This goes on year after year. Now that the plant has gotten its growth, it is more hardy, and is constantly sending up new shoots. If the bed is well made in the beginning, the asparagus need not be disturbed for eight or ten years. However, at the end of that time it is well to take the plants up and fill the beds with fresh soil and manure.

In the spring, when the sun gets high, the asparagus houses are shaded with a light coating of white lead, whiting and kerosene oil. This is absolutely necessary, as the summer sun would in a very short time burn the tops of the vines. The vine flowers in the fall, and only on strings that have been matured six months or more.

The vine alone is not the only source of profit. When the plant is a year old, a few of the most nearly perfect sprays may be taken without injuring its growth. These are very desirable in the market. There is, of course, some waste in working up the Asparagus to be shifted, but on the whole, it is very slight. The different forms in which it is sold utilize by far the greater part of it.

Insects destroy the shoots and sprays. This is prevented to a great extent by insect powder. The cut-worms do the most damage. About the only way to get rid of them is to pick them off the strings during the night, as they generally seek shelter under the thick clusters of the plant at daylight.

There are many drawbacks in growing asparagus, among which are expensive houses, the slow growth of the plants (which makes it necessary to wait at least two years before receiving any return from the expenditure), injury from insects, and the great amount of labor involved in looking after the houses.

William H. Elliott.

FERNS, POPULAR NAMES OF. **Adder's Tongue F.**, *Ophioglossum vulgatum.* **Asparagus F.**, *Asparagus plumosus.* **Beech F.**, *Phegopteris.* **Bird's-nest F.**, *Asplenium Nidus.* **Bladder F.**, *Cystopteris.* **Boston F.**, *Nephrolepis exaltata* var. *bostoniensis.* **Brake**, *Pteridium.* **Bristle F.**, *Trichomanes.* **Buckler F.**, *Dryopteris.* **Californian Gold F.**, *Ceropteris triangularis.* **Chain F.**, *Woodwardia.* **Christmas F.**, *Polystichum acrostichoides.* **Cinnamon F.**, *Osmunda cinnamomea.* **Climbing F.**, *Lygodium.* **Dagger F.**, *Polystichum acrostichoides.* **Deer F.**, *Lomaria.* **Elk's-horn F.**, *Platycerium alcicorne.* **Female F.**, *Asplenium Filix-fœmina.* **Filmy F.**, *Hymenophyllum.* **Floating F.**, *Ceratopteris.* **Flowering F.**, *Osmunda*; sometimes also *Anemia.* **Gold F.**, *Ceropteris.* **Grape F.**, *Botrychium.* **Hart's-tongue F.**, *Phyllitis Scolopendrium.* **Hartford F.,** *Lygodium palmatum.* **Hay-scented F.,** *Dennstædtia punctilobula.* **Holly F.,** *Polystichum Lonchitis.* **Lace F.,** *Cheilanthes gracillima;* also *Dryopteris intermedia.* **Lady F.,** *Asplenium Filix-fœmina.* **Lip F.,** *Cheilanthes.* **Maidenhair F.,** *Adiantum;* more particularly *A. FERÒNIA (from Feronia, Roman goddess of forests). *Rutàceæ,* tribe *Cìtreæ,* subtribe *Feronìnæ.* Spiny deciduous tree with hard-shelled fruit; related to Citrus, for which it can perhaps be used as a stock.

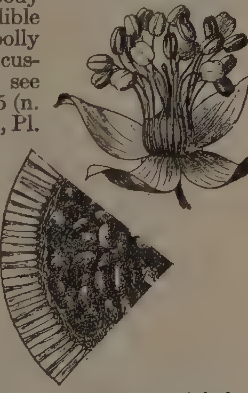
Leaves odd-pinnate, deciduous: fls. small, perfect or by abortion male in terminal or axillary panicles; petals 5 (rarely 4 or 6); stamens twice as numerous as the petals; filaments much longer than the anthers, dilated at base and densely pubescent on the sides and within; ovary at first 5-celled, later becoming by confluence 1-celled: fr. with a hard, compact woody shell; seeds oval, lenticular, with a thin hairy brown testa immersed in an acid edible pulp; cotyledons fleshy, aërial in germination.—Only 1 species is known.

Limònia, Swingle (*Schìnus Limònia,* Linn. *Limònia acidíssima,* Linn. *F. elephántum,* Corr.). Wood-Apple. Spiny deciduous tree, native to India, Ceylon and Indo-China: bark gray, rough: lvs. odd-pinnate, 3–7-foliate; lfts. opposite, obovate, blunt at the apex, sometimes emarginate, entire-margined with a short petiolule; rachis margined, articulate, spines long and straight, axillary: fls. (sometimes male by abortion of the ovary) dull red, small, in terminal or axillary long-pedicelled panicles; petals 5 (rarely 4 or 6); stamens 10 (rarely 8 or 12), filaments short, dilated at base and densely pubescent on the sides and within; anthers large; ovary 5-celled, with many ovules in each cell; stigma cylindrical, sessile: frs. globose or oblate, 2½–3 in. diam., having a hard, woody rind filled with a pinkish edible pulp in which the numerous woolly seeds are immersed. For discussion of name and synonomy, see Journ. Wash. Acad. Sci. 4:325 (n. 12, June 19, 1914). Ill. Roxbg., Pl. Coromandel., Pl. 141. Gt. 34:1206. Wight, Ic. Pl. Ind. Or., Pl. 45; Beddome, Fl. sylvat. South Ind., 1:121; Talbot, For. Flor. Bombay, fig. 124; Engl. & Prantl, Nat. Pfl.-fam. III. 4, 193, fig. 112.—The pulp of the fr. which is acid, is used for making jellies somewhat similar to black currant jelly. It is also made into a kind of chutney with oil, spices and salt by the natives of India. The fls. and lvs. of this tree have an odor of anis and are used as a stomachic. The commonly cult. species of Citrus can be grafted on this plant and wood-apple seedlings are now being tested as stocks by the U. S. Dept. of Agric. in Calif. and Fla. and also in the greenhouses in Washington, D. C.

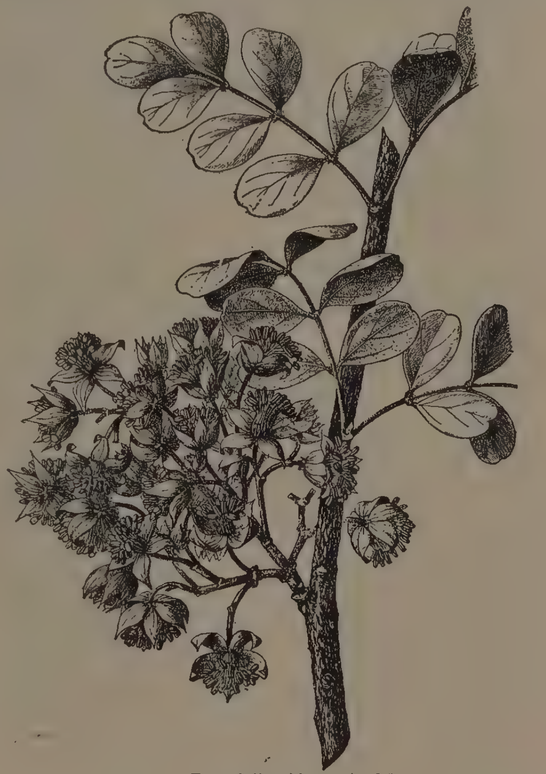
Walter T. Swingle.



1493. Flower and fruit of Feroniella oblata. (fl. nat. size, fr. ×⅔.)

FERONIÉLLA (diminutive of Feronia, Roman goddess of forests). *Rutàceæ,* tribe *Cìtreæ,* subtribe *Feronìnæ.* Small much-branched spiny tree, related to Feronia and suggested as a possible stock for citrous fruits.

Leaves odd-pinnate, persistent, 3–6-paired; rachis cylindrical, sometimes narrowly winged; spines solitary, in the axils of the lvs.: fls. in much-branched axillary infl., perfect or by abortion male, usually 5-parted, having 4 times as many stamens as petals; filaments much longer than the anthers, dilated at base and having a hairy appendix on the inner side; style long, stigma cylindric, caducous; ovary at first 5–6-celled, later becoming by confluence 1-celled: fr. spherical or depressed globose, with a hard shell composed of radially arranged prismatic elements; pulp edible; seeds numerous, oblong or elliptical, with a smooth crustaceous testa; cotyledons aërial in germination.—Two species are known.



1494. Feroniella oblata. (×⅔)

oblàta, Swingle. Krassang. Figs. 1493, 1494. Spiny tree, 25–65 ft. high, native to Cambodge and Cochin-China: lvs. odd-pinnate, 3–4-paired; lfts. covered with small whitish hairs, especially when young, pellucid-punctate, oval or obovate, crenulate when young, often emarginate, with a very short petiole; rachis pubescent; fls. in many-fld. panicles, white, very fragrant, usually 5-parted, with lanceolate pointed petals; stamens 4 times the number of petals, anthers large, oval, filaments joined together at the base by the woolly pubescence of the appendices occurring on their inner side: fr. borne in clusters of 3 or 4, flattened spheroid, 2 to 2½ in. diam.; pulp subacid, pinkish, edible. Ill. Swingle in Bul. Soc. Bot. de France, 59, pl. 18 and fig. *a,* p. 778. Lecomte, Fl. gén. Indo-Chine, 1:685, fig. 72, 1–5.—This species occurs commonly in the forests of Cambodia and is sometimes cult. by the natives for its frs. which, when young, have a pronounced orange odor and are used as a condiment in sauces. Young plants of this species are growing in the greenhouses of the Dept. of Agric. at Washington, D. C.

lùcida, Swingle (*Ferònia lùcida*, Scheff.). Kavista Batu. Small spiny tree, native to Java: lvs. odd-pinnate, 3–6-paired; lfts. oval or obovate, coriaceous, shiny above, margins entire or slightly crenulate, obtuse or emarginate at the apex; petioles pubescent, the terminal lft. sessile; rachis pubescent, articulated: fls. perfect or by abortion male, fragrant, white, rather large; sepals small, linear, pubescent; petals pointed-oval; stamens 4 times as many as the petals: fr. globose 2½–2¾ in. diam.; seeds small, with a thin hard testa, immersed in the glutinous pulp. Ill. Icones Bogor. 2:149.—The pulp is sometimes eaten in Java, like that of the wood-apple (*Feronia Limonia*). It grows wild in the drier parts of Java and has been intro. into the U. S. where it is being tested by the Dept. of Agric. as a stock for citrous fruits.

Walter T. Swingle.

FERRÀRIA (Giovanni Battista Ferrari, 1584–1653, Italian Jesuit, botanical writer and collaborator with the celebrated artist Guido Reni). *Iridàceæ.* Half-hardy bulbous plants from the Cape of Good Hope (and recent species from other parts of Africa), rarely growing more than 6 inches high.

Corm large and irregular: foliage glaucous; lowest lvs. long and linear, the others ovate, clasping, successively smaller, and topped by inflated sheaths from which emerge the fugitive fls.; these have 6 triangular, spreading, crisped, petal-like lobes, marked with many dull colors, as yellow, green, purple and brown; each spathe contains several fls., and the fls. are united at the very base, connivent and cup-shaped below the spreading lobes; the fls. last only from morning to afternoon of a single day, but there is a fair succession; some are visited by carrion flies: fr. an ellipsoid membranous caps.—Only one species, *F. undulata*, is much known in cult., but the other 5 or 6 species of the Cape are doubtless of equal interest. This was known to pre-Linnæan authors as *Flos indicus* and *Gladiolus indicus*. The bulbs should be stored like gladiolus in a dry, warm place, away from mice.

A. *Fls. dull brownish purple.*

undulàta, Linn. St. stout, erect, sometimes exceeding 1 ft: basal lvs. sword-shaped, 1 ft. and more long, flat, clasping and dilated at base; upper lvs. and spathes 1½–2 in. long: fls. 2 in. across, largely dull purple; anthers oblong, with parallel cells. B.M. 144.

AA. *Fls. greenish.*

uncinàta, Sweet. St. short, little branched: lvs. 2–3, linear: fls. 2, the perianth greenish and with narrow very acuminate segms. 1 in. long; anthers small, the cells nearly parallel.

AAA. *Fls. dark purple.*

atràta, Lodd. St. about 6 in.: lvs. about 4, sword-shaped, firm, strongly ribbed, twice longer than st.: fls. 3–4, bright dark purple, 1½–2 in. diam. when expanded; anthers oblong, with cells parallel.

Other names are advertised by Dutch bulb-growers, as *F. canariensis, F. cælestis, F. conchiflora, F. grandiflora, F. immaculata, F. liliacea, F. rosea, F. Pavonia:* these are to be sought under Tigridia.

Wilhelm Miller.

FERTILITY of soils: that condition of soils which makes them productive. The elements of productivity are, a full supply of available plant-food, a suitable and continuous supply of moisture, good physical conditions of the soil, coupled with suitable seed and climate.

Land may contain vast quantities of potential nitrogen, potash, phosphoric acid and other plant-food, and yet be unfruitful,—infertile. Most of the potential plant-food in the soil is lazy, or not available in sufficient quantities in a single season to produce maximum crops. Average arable land which contains from 3,000 to 4,000 pounds of nitrogen, an equal amount of phosphoric acid and four times as much potash in the first 8 inches of an acre, may produce only fifteen bushels of wheat to the acre, which requires, with the straw, but twenty-four, thirteen and twenty pounds of these three elements respectively. Therefore, land may contain a great abundance of potential plant-food, and yet not contain enough of that which is available for a full crop. To make land more fertile, one or more of the following means may be employed. Usually deeper and more thorough tillage should first be resorted to, since most lands, by reason of careless farming, contain much inert plant-food. Superior tillage is almost certain to produce fruitfulness, and therefore should be resorted to before more expensive methods are tried. Tillage not only makes plant-food more available, but it improves the physical conditions of the soil, thereby making it more adaptable to the plant; it may also assist in relieving the land of surplus water, and give to the soil the power of retaining stores of moisture by capillary action.

Moisture plays such an important part in productiveness that it may be said to constitute its prime factor. Clay soils are usually composed of such fine particles that water percolates through them slowly, hence the larger part of the rainfall must either run off over the surface, or remain to be evaporated. The aim should be so to prepare the land by subdrainage, plowing and surface tillage, and by introducing at least one crop of tap-rooted plants in the rotation, that the surplus water will filter through the soil in a reasonable time. Percolation of rainwater through soils makes them more friable and warmer in spring, aërates the land, promotes beneficial biological and chemical changes, and brings to the soil the nitrogenous compounds contained in the rainwater. Soils that are reasonably porous have the power of retaining more moisture, and of giving it up to plants, when needed, to a greater extent, than either open sandy or close clay soils. Fertility, which results in fruitfulness, is governed very largely by the water and moisture conditions of the soil, and these, in turn, are to a considerable extent governed by the texture of the land and the amount of humus that it contains.

Legumes, used either as a harvest or cover-crop, promote fertility. A cover-crop of clovers planted August 1, and analyzed sixty-four days after planting, contained nitrogen, in roots and tops, to the acre as follows:

	Tops Pounds	Roots Pounds	Total Pounds
Crimson clover	125	30	155
Red clover	63	40	103
Mammoth clover	67	78	145

Clovers and other legumes may be used to fix and store up the uncombined nitrogen of the air and to digest and make available the mineral constituents of the land, thereby greatly increasing the fertility of the soil.

In most of the semi-arid districts of the United States, except where irrigation can be successfully undertaken in the rich valleys, the problem of permanently maintaining and increasing the productivity of the soil is as yet unsolved. Better tillage may serve in many cases to prolong the time of profitable cultivation, but unless something is done toward restoration it only postpones for a short period the day when the land must be left to the tooth of time and to the growth of such hardy plants as can maintain themselves on a depleted soil. All such pasture lands may be greatly benefited by sowing, even in small quantities, in early spring with red and alsike clover in humid districts, and bur clover in the rainless-summer regions. Lands adapted to orcharding that have become depleted and that have a tenacious subsoil may be benefited by exploding a charge of dynamite in a hole about 1 inch in diameter and 2 feet deep at each place where a tree is to be set. Such treatment tends to promote filtration, to set free plant-food by aëration and to improve the physical condition of the adjacent soil, while at the same time it lessens the labor necessary to prepare the ground for tree-setting.

Barn manures, when properly cared for and intelligently applied, not only furnish acceptable plant-food but humus as well. Fertility and high productivity usually may be maintained many years by means of superior tillage, leguminous harvest and cover-crops, and the manures of the farm. In some cases a high state of fertility can be maintained only by occasional applications of commercial mineral fertilizers, such as phosphates and potash, but too often expensive fertilizers have been substituted for tillage, leguminous plants and barn manures.

Fertility may frequently be promoted by light applications (ten to twenty bushels to the acre) of quicklime. Lime serves to make plant-food more available, to improve soil texture and to correct acidity. It may also be applied beneficially to a green-manure fallow. Lime tends to sink into the soil, therefore it should be applied after the last plowing preceding the seeding, and should be covered and mixed with the soil by tillage. Hydrated, or biting lime, not only tends to set free plant-food but to flocculate the soil, thereby improving its physical condition. Its use is especially recommended on clay and moist lands and in orchards where the ground is much shaded. Applications of gypsum and salt are sometimes beneficial in maintaining fertility, but they, as well as lime, usually act indirectly, as the soil is seldom deficient in these constitutents so far as they are required as plant-food. On high-priced lands, especially those devoted to horticulture, the soil should be made and kept fertile—well up to its highest productive power.

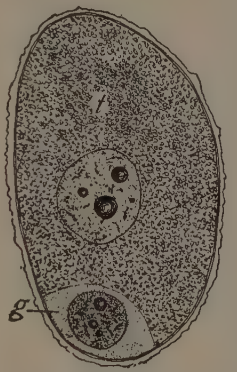
A bare summer fallow of one to three plowings and suitable surface tillage will not only destroy weeds, but liberate plant-food as well, while storing moisture in the soil for the immediate use of young plants. But a bare fallow, if not accompanied by the addition of some plant-food, may hasten the depletion of the soil. It is a matter of judgment, then, as to whether the particular soil contains such abundant supplies of plant-food that some of them may be removed; or whether it is very deficient. In the latter case a green fallow would be far preferable to a bare one. In many cases a bare fallow is merely a method of mining-farming which hastens the time when the land must be turned out to pasture for economic reasons. Often productivity is increased more satisfactorily by means of green-manuring than by bringing plant-food to the land from outside sources. In most of the humid districts early sowed peas (which withstand late frosts) followed by buckwheat, and both plowed under some time before they mature, can be grown in time to fit the land for seeding in September to wheat, rye or timothy, the nurse crop being omitted. When the land might be made too porous by this method, rye sowed in the fall, plowed under before coming to head and followed by peas, would greatly improve the light and sandy soils by bringing stores of nitrogen and humus.

Nature, in producing and storing fertility, provides a great variety of plants and an infinite number of ways of multiplying them so that the land is fully covered with vegetation—except in desert regions. Upon the best of these lands a vast animal life is maintained while the remainder produces other plants to feed other animals. In the densely settled agricultural districts of China, for the last two thousand years the farmers have been returning as much to the land as they have taken from it; and the soil is now more productive than it was when first brought into cultivation. The problem of conservation and restoration of soils is now in America the most serious one the agriculturist has to solve.

Sometimes soils are rendered unfruitful by the presence of deleterious substances, as organic acids or alkaline salts, or a superabundance of some one or more of its usually useful ingredients, as water or nitrogenous compounds. An excess of nitrogen stimulates the growth of stalk and straw at the expense of grain, or in the orchard it tends to the formation of wood rather than to fruitfulness. The acidity should be corrected by lime, as noted above, the surplus water removed by drainage, the nitrogenous matter reduced by the production of such crops as are not harmfully affected by its superabundance, such as forage crops which are prized for their foliage rather than for their seeds, while the alkalinity may sometimes be overcome by deep tillage, irrigation or application of gypsum in suitable amounts.

I. P. Roberts.

FERTILIZATION is the fusion of sexually differentiated cells, and with special reference to the seed plants it means that a cell (a fertilized egg, or zygote) is thus formed which is capable of developing into the embryonic plant later recognized in the plantlet of the seed. The fusing cells, or gametes, are (1) the egg (female cell), which is organized in the ovule, as described below, and (2) a sperm-cell, or nucleus (male cell), developed in the germinating pollen-tube. Fertilization is a process which may not be readily observed in the seed-plants except through the use of careful histological methods, both in the fixation of material and in the subsequent processes of imbedding and staining. The phenomena are illustrated in Figs. 1495–1497.

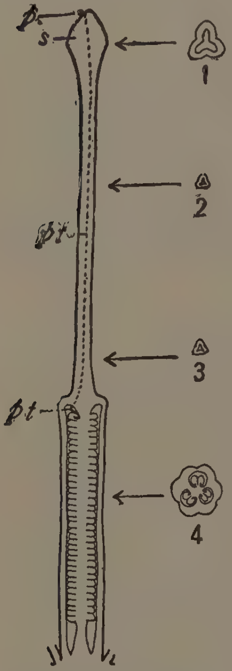


1495. A pollen-grain of Lilium philadelphicum.

Section of a single grain before the anther opens; *t*, the tube-cell; *g*, the generative cell. The large spherical body in each cell is the nucleus. (Magnified 500 diameters.)

The term "fertilization" has always implied the union of male and female cells; but formerly, when less was known regarding the details of the phenomenon, "fertilization" included the mere mechanical process whereby pollen from the anther was transferred by any agent to the stigma of the flower. For this reason "fertilization by insects" or "fertilization by wind"—meaning the transfer of pollen by these agencies—are frequent expressions in the work of Darwin and Wallace. In this last-mentioned sense, the word pollination is appropriate, and now commonly employed. If the silks of corn are pollinated with corn pollen, fertilization normally ensues and seeds are produced; but if the corn-silks are pollinated by the pollen of the lily, no seeds will be formed. It is obvious that cross-pollination has no limits; but cross-fertilization is limited to those cases in which the sexual cells unite and a new organism develops.

The development of some structures essential in fertilization are of interest in this connection. The mature pollen-grain consists of a large tube-cell and nucleus and a small generative cell and nucleus. When lodged upon a suitable stigma the pollen-grain germinates by the development of a tube which enters the loose tissue of the stigma and grows further into the conducting parts of the style. In some cases, definite stylar canals are present, but usually the tube wedges itself between the yielding cells, absorbs nutrient in its course, and forces or dissolves its way to the ovule or seed-case, where, as a rule, it enters the micropyle and approaches the embryo-sac and egg-cell. In its course the pollen-tube is doubtless "directed" by the distribution of food. Meanwhile, the generative nucleus of the pollen-tube divides into two sperm (male) nuclei, and these migrate to the growing end of the tube.



1496. Outline of a pistil of Lilium philadelphicum.

A lengthwise view of pistil almost through the center; *s*, stigma on which pollen-grain, *p*, has been lodged. The course of the pollen-tube, *pt*, is indicated by broken line. At the right, *1*, *2*, *3*, *4*, are cross-sections of the pistil at the levels indicated by the arrows: *1*, the stigma; *2*, *3*, the style, show the triangular canal which leads into the three chambers of *4*, the ovary, in each chamber of which are two rows of ovules. (Natural size.)

With the formation and opening of the flower, the embryo-sac attains its development. This structure is too complex to require full treatment here, but it is sufficient to say that, when approaching maturity, it consists of one large cell containing eight nuclei, four of which collect at each end of the cell. One nucleus from each end marches to the center, and the fusion which then commonly results gives a nucleus the divisions of which ultimately organize a so-called food, or endosperm, tissue, which may surround the embryo when formed.

At the micropylar end of the embryo-sac, another nucleus organizes the egg-cell—a prominent cell with considerable protoplasm—and the other two degenerate or form the subsidiary cells of an "egg apparatus." The cells at the antipodal end of the embryo-sac are also of little present significance. At about the time of the maturity of the egg-cell the tip of the pollen-tube reaches and penetrates the wall of the embryo-sac, then dissolves and liberates the two male nuclei. One of these fuses with the egg-cell, and this is the important act under consideration. The other sperm nucleus often fuses with the endosperm nucleus, but that does not affect the characters of the embryo. The fusion of egg and male nucleus unites, on the other hand, the characters of the ovule-bearing and pollen-bearing plants in the fertilized egg, which may proceed immediately to develop the embryo.

B. M. Duggar.

FERTILIZERS. It is now well recognized that shade trees, ornamental shrubs, small fruits, and flowering perennials, as well as annual flowering and foliage plants, are often as greatly benefited by the use of proper fertilizers and manures as vegetables and ordinary farm crops. There are, nevertheless, occasional soils on which fruit trees, and shade trees in particular, require little or no artificial fertilization or manuring. For example, it was not found profitable to fertilize apple trees at the Agricultural Experiment Station in Geneva, New York, whereas at the Pennsylvania Agricultural College the use of fertilizers was not only strikingly helpful, but practically vital to successful orcharding. Instances of such contrasts in connection with trees and shrubs are always to be expected. On this account the giving of rule-of-thumb directions for fertilizing, in a work of reference which is designed to be generally applicable to the entire United States, is not only well nigh impossible, but may, if followed, lead to the most unreasonable procedure on the part of those not sufficiently conversant with their own particular soil conditions. For this reason this discussion will be confined largely to the general principles involved, since they not only fail to mislead the novice, but may serve as a safe and rational basis for general procedure for all.

Shade trees, ornamental trees and shrubs.

Because of the fact that trees have an extensive root-system, and hence possess a wide feeding range, they often stand less in need of artificial manuring and fertilizing than certain shrubs, especially if the latter have already been set for a long time.

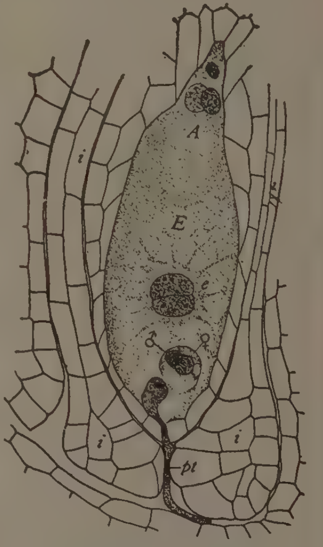
It is to be presumed that most soils contain enough iron and magnesia to meet the needs of trees and shrubs, yet since these substances are just as essential to their growth as any of the three so-called "essential elements," it is well to bear in mind that very rare cases may be met with in which even iron or magnesia may be helpful. In this connection it may be mentioned that the soil in a section of northern Michigan is said to contain so little iron that certain farm animals, if fed exclusively on the plants which grow there, cannot be reared successfully. It has even been found that manganese compounds are sometimes helpful to plants, and if the supply of iron is insufficient, they aid in promoting chlorophyl formation in the leaves, without which the higher plants cannot exist.

Some soils are relatively deficient in magnesia as compared with lime, and when such is the case, growth is likely to be restricted until enough magnesia is added to create a proper balance between the two. A much more frequent lack, in soils of the humid regions, is lime.

Unfortunately, an extended and systematic study of the lime requirements of trees and shrubs has not yet been made, although many valuable isolated observations are on record. It would be of great value if such experiments were conducted on an extensive scale. Such experiments as were made in this direction in Rhode Island showed, for example, that the American elm (*Ulmus americana*) and the basswood (*Tilia americana*) were both greatly helped by liming when grown on the very acid granitic soil of that state. From this it may be inferred that benefit from liming would also follow on many of the soils of the humid regions which are derived chiefly from granite and from certain of the sandstones, shales, slates, gneisses, schists and conglomerates.

The sugar or rock maple was found to be but little helped by lime, even where the elm and basswood showed striking benefit. The common white birch seemed to be even less responsive to liming than the sugar maple.

The use of much



1497. Section of an ovule of Lilium philadelphicum.

Cut lengthwise; *i*, *i*, inner integument, inclosing except at a narrow orifice (micropyle) where the pollen tube, *pt*, enters the body of the ovule which is chiefly occupied by the large embryo-sac with three nuclei, one much disorganized. *e*, the endosperm nucleus, just being formed by fusion of two nuclei from the respective ends of the embryo-sac. ♂, male nucleus, which has just migrated from pollen-tube and is about to fuse with ♀, the egg nucleus. The synergidæ, or "egg apparatus," have disappeared. (Magnified 670 diameters.)

lime may sometimes interfere with the growth of the Norway spruce. It is also unfavorable to at least some of the pines. The effect of liming on certain of these conifers is observable not only by way of its lessening the growth of the tree, but also by its causing a shortening of the needles.

The chestnut tree is reputed not to need liming, but even to be seriously injured, if lime is used.

Among the flowering shrubs, general experience points to the fact that lime should be avoided in connection with the growth of the laurels, rhododendrons, azaleas and the Ericaceæ generally. There is, however, no doubt as to the benefit to be derived from the use of lime in connection with many of the other ornamental and flowering shrubs. Experiments by Hogenson appear to show that sulfate of magnesia may sometimes be very helpful to certain shrubs which are ordinarily injured by lime, although this work needs to be extensively supplemented before being accepted as a sure basis of procedure.

In general, the need of nitrogen for trees and shrubs is indicated by insufficient limb and leaf growth, although any other lacking essential ingredient may ultimately have the same limiting effect.

Whenever trees or shrubs are being set in poor land, it is well to work into the soil generous amounts of ground, steamed bone or superphosphate. The latter phosphate possesses, however, a very distinct advantage for subsequent application, due to its high content of soluble phosphoric acid. Basic slag meal should be avoided for those trees and shrubs likely to be injured by lime, whereas for others it may be employed at the time of planting. These materials may be used when the trees or shrubs are set, if well mixed with the soil, and from one to four pounds may be used for a tree or shrub, according to their size.

High-grade sulfate of potash or muriate of potash may be similarly worked into the soil at the rate of half a pound to a pound a tree when potash is known to be deficient, but even in such cases it is sometimes advisable to withhold it until a year after setting, and then make the application alone, in conjunction with superphosphate, or in a complete fertilizer. Twice as much double manure salt or four times as much kainit is required to replace either the sulfate or the muriate of potash.

If the growth is not satisfactory, after the trees or shrubs have been set for some time, a complete fertilizer containing from 2 to 4 per cent of ammonia, from suitable sources, may be worked into the soil about the trees or shrubs, or it may even be scattered on the surface of the ground, in case the land is kept in grass.

Care should be taken to keep the fertilizer away from the base of the trees or shrubs, and it should be applied for at least a considerable distance beyond the reach of the branches. For this purpose, quantities of fertilizers, ranging from two to thirty-five pounds, may be used for each tree, according to its kind, size and age, although even for large shrubs, from two to six pounds will usually be sufficient.

Just as the keen observation of the feeder is necessary in the fattening of the animal, so also the judgment of the experienced gardener is essential to the proper gaging of the amounts of fertilizer for trees and shrubs of all kinds.

Much is claimed, by those who have had experience in renovating old trees, for the plan of making a large number of holes under the tree, to a depth of 1 foot to 2½ or 3 feet, and placing the fertilizer in these holes. This procedure has much justification, owing to the great "fixing" power of the soil, especially for phosphoric acid and potash salts which are otherwise prevented from being quickly and readily carried down in large quantities to points where the deeper roots can immediately reach them. Even if fertilizer is employed in this manner it is also well to apply some of it to the surface, in order to insure an even lateral distribution of at least a part of it.

Another drastic method of procedure in renovating old trees is to trench around a part or the whole of the tree, at a suitable distance from the trunk, to a depth of several feet, and then fill the trenches with new soil mixed with manure and a complete fertilizer containing slowly-acting phosphatic and nitrogenous materials, and suitable amounts of potash salts. In such a case it is a part of the plan to cut off many of the ends of the old roots in order to make them branch and thus increase their feeding capacity.

Apples and pears.

Apple trees, as a rule, respond to liming rather better than pear trees; nevertheless, on very acid soils there are several good reasons for liming even pear trees. An occasional application of magnesian lime may be desirable, but if used it should be alternated with applications of purer lime.

On land known to be very rich naturally, or which has been highly manured for a series of years, neither fertilizer nor manure will be required for newly set apple or pear trees, and in only exceptional cases will they be needed, even for those just coming into bearing. When such exceptional conditions do not exist, it is usually a safer plan to fertilize the land with liberal amounts of potash, phosphoric acid, and rather slowly available sources of nitrogen, or else to employ such small amounts of quickly available nitrogen as will surely be used up before or by midsummer. If, on the other hand, excessive amounts of farmyard manure or nitrogenous fertilizers are applied, or if the application is too long delayed, late growth is promoted, with the result that the wood remains too soft. In such cases cracking and other serious injury is likely to follow during the winter season.

As a rule, the orchard may be used to advantage for some years after the trees are set, for the growing of quick-maturing crops, such as peas, early cabbages, radishes, and potatoes, or even for tomatoes, melons, or squashes. These crops may be well fertilized, and many of the earlier ones can be followed in the late summer by a cover-crop of crimson (scarlet) clover, or hairy vetch. If the soil is already rich enough, or is too rich, in nitrogen, barley or rye may be substituted for the legumes. These cover-crops can then be plowed under the next spring. Some growers even prefer weeds to any of these cover-crops because of saving the outlay for seed.

When the stage is passed in which extended cropping between the trees is possible, and the burden of fruit becomes great, especial care should be taken to apply an abundance of potash and phosphoric acid annually, and only enough nitrogen from legumes or fertilizers to insure adequate foliage, satisfactory wood-growth, and abundant fruit-spurs. For this purpose a suitably compounded complete fertilizer may be employed. If legumes are found to supply enough nitrogen one may employ annually from 200 to 600 pounds an acre of acid phosphate or basic slag meal, and from 50 to 400 pounds an acre of the muriate or high-grade sulfate of potash. If the double manure salt is used as the source of potash instead of the muriate or the high-grade sulfate of potash, the total application should amount to approximately twice as much an acre, because of its lower potash content.

The nitrogen for the orchard may be supplied in one, or, on light open soils, in two applications of nitrate of soda at such a rate that the total application for a season will not exceed from 100 to 300 pounds an acre, dependent upon the slowness of the growth of the trees. It is usually much simpler to make a single application of a complete fertilizer, in which the nitrogen is present in nitrates, ammonium salts, soluble organic compounds and in less quickly available organic forms, than to apply nitrates at two or more different times. When such complete combinations are used the danger of loss by leaching is greatly lessened and a satisfactorily continuous but properly decreasing supply of nitrogen for the trees is assured. The fertilizer application should not be made later than just after the time the fruit has set. Many good authorities even advise waiting until this time in order to gage the application according to the probable yield and requirement of the trees.

At the Massachusetts Agricultural Experiment Station, far better results were secured with double manure salt (sulfate of potash and sulfate of magnesia) than with muriate of potash, but in experiments elsewhere the muriate of potash has given as good results as the high-grade sulfate of potash. It is probable, in view of the known lack of carbonate of lime in the Massachusetts soil, that this rather serious deficiency was responsible for the poorer results with muriate of potash, for in soils elsewhere where the lime supply was sufficient, muriate of potash has acted well. It is, of course, possible that the magnesia of the double manure salt was helpful in the Massachusetts experiments. The results furnish, however, no positive evidence to that effect, but indicate strongly that the chlorin of the muriate of potash was probably injurious because of a lack of carbonate of lime.

The idea that the proportion of the various fertilizer ingredients affects the color of apples in a direct way has little to support it. It is rather tenaciously claimed, nevertheless, that basic slag meal has special value in adding color to apples, but this may be due solely to its adding a proper balance of mineral ingredients which could perhaps be equally well supplied by other phosphates. There is abundant evidence, however, that over-fertilization with nitrogen leads to the development of exceptionally heavy and abundant foliage; and the excessive shading lessens the color of the fruit. Direct exposure of the apple to the sunlight also lessens its tendency to shrivel. This is due, probably to its effect either on the proportion of the various chemical constituents of the skin, or to its thickness, by which evaporation of water is hindered. In order to insure even distribution of the color on the individual apples, severe thinning is essential, for otherwise one apple will partially shade another.

In some European countries the fertilizer for orchards is placed from 4 to 5 inches deep in holes 20 inches apart, at the rate of about an ounce and a quarter a hole. This method is, however, probably too expensive to employ in this country, though it may be especially effective for orchards which are in sod. If the work were capable of being done by machinery or by some suitable implement the method might possibly prove of economic value.

Peaches.

Peach trees are less in need of lime than apple trees, yet liming is nevertheless often desirable, even for its indirect benefits. The fertilizer required for peaches is much more than for apples, for the reason that the trees grow far more rapidly and bear early and abundant crops. On poor soils generous fertilizing must be provided from the outset, but if the land is very rich or heavily manured, fertilizer may be omitted for the first year or two. If a soil is very poor it should receive at the outset from 300 to 500 pounds an acre of a fertilizer containing a moderate amount of nitrogen derived from appropriate materials, a fair quantity of available phosphoric acid, and a generous amount of potash in muriate of potash. On soils in which potash is naturally very abundant, the supply can be greatly lessened.

When the peach trees come into bearing, more nitrogen will be required than at the outset, and the total quantity of fertilizer may then be increased one-half, or even more than doubled. In the case of peach trees, constant watchfulness is required to make sure that neither too little nor too much nitrogen is used. An excess of nitrogen will prevent proper ripening of the fruit, and of the wood in the autumn, whereas too little will mean abbreviated crops, loss of vigor, and at the same time the lack will create conditions favorable to disease. In any case, ample supplies of phosphoric acid and of potash, as muriate, should be provided to meet any possible need. If a little extra nitrogen is required in the spring, it may be applied in nitrate of soda, or, if the soil is properly limed, sulfate of ammonia may be substituted for the nitrate of soda if desired.

In case one wishes to stock the land with phosphoric acid in advance, large applications of bone or basic slag meal may be made, ranging from 400 to 1,000 pounds an acre of the former and from 500 to 1,200 pounds an acre of the latter. The old plan of heavily stocking the soil and waiting a long time for the returns is, however, giving way to the frequently more economical plan of more nearly meeting the fertilizer needs from year to year, instead of tying up a large amount of money in a long-time investment.

Plums, cherries and apricots.

The plum and cherry, regardless of whether the latter is a sour or sweet variety, are certainly far more in need of liming than the peach, but data are not at hand as to the relative requirements of the peach and apricot. The fertilization of these fruits should not vary widely from the treatment required for peaches, excepting that the quantity may be rather less, and the same care should also be exercised not to use excessive amounts of nitrogen.

Blackberries, raspberries, gooseberries and currants.

The blackberry is especially at home on very acid soils and a very light application of lime will meet all possible requirements of the plants, if indeed it is needed at all. The blackcap raspberry is more likely to be helped by liming than the blackberry, although it is well adapted to moderately acid soils. The Cuthbert raspberry is appreciably helped by liming on quite acid soils, and the same is probably true of most or all of the red and yellow varieties. The gooseberry and currant, including the white and various red varieties are greatly benefited by liming. As much as two to four tons of ground limestone an acre, or its equivalent of slacked lime, are often very helpful to these plants. Raspberries, in particular, thrive well on a heavy, freshly rotted sod, as for example, on old grass land plowed the autumn before the plants are set. In many cases all that is required on such land is to supply an adequate mixture of an available phosphate and a potash salt, but whenever the cane growth is weak and unsatisfactory, or, when gooseberries and currant bushes do not show satisfactory growth, a moderate amount of complete fertilizer containing a fair amount of nitrogen in gradually available forms is likely to be beneficial. The use of heavy applications of nitrogen for raspberries, currants and gooseberries is not advised, for it will induce too great a growth of canes and foliage and interfere with the maturing and ripening of the fruit. The plants will also be rendered more readily subject to mildew.

Strawberries.

The strawberry grows well on moderately acid to very acid soils, and if lime is used the application should be light, rarely exceeding 1,000 to 2,000 pounds of ground limestone an acre.

An important point to be recognized by strawberry-growers is, that weak plants are not likely to be heavy bearers the next year. In consequence, the plants when set should be supplied with a fertilizer reasonably rich in available nitrogen. This fertilizer should usually be applied at the rate of 1,000 to 1,500 pounds an acre at the time of setting, and in the later years just after picking the crop of fruit, fertilizer may be scattered in a furrow turned away from each side of the bed, after which the furrow may be turned back again. Early each spring fertilizer should be applied broadcast over the beds. This should contain liberal quantities of soluble phosphoric acid and potash but only enough nitrogen to promote reasonable growth. This nitrogen should, however, be largely in readily soluble and available form. If too much nitrogen is used in the spring the fruit will lack color, and it may be soft and unsatisfactory, especially for distant shipment. It may even be necessary to omit all nitrogen in the spring, if the soil is exceptionally rich in humus or has been well manured previously. This can only be decided by the observant grower.

On many soils superphosphate is preferable to basic slag meal as a source of phosphoric acid for strawberries, for the reason that too much lime is to be avoided, and furthermore, the phosphoric acid is largely soluble and better adapted to top-dressing. On an exceedingly acid soil the use of basic slag meal may be permissible for application at the time of setting, for the action of the soil aids in rendering it available to the plants.

Grapes.

Grapes may show some gain from the use of lime under certain circumstances, but they do not require it in even approximately the same degree as the cherry, plum, currant, and gooseberry. The chief need of this crop is available phosphoric acid and potash. If nitrogen is used, the quantity must be carefully regulated, and in Europe slow-acting forms of organic nitrogen are in special favor. Basic slag meal or bone-meal may be used as sources of phosphoric acid when the grapes are set, but later, superphosphate is to be preferred, especially if it is not most thoroughly worked into the soil. Sulfate of potash is often considered preferable to the muriate of potash for grapes, for it is alleged to give a better quality of fruit.

Quinces.

The quince responds to liming in about the same degree as the cherry and plum. It should receive enough nitrogen to insure reasonable growth, but no more; and on exhausted soils a moderate amount of available phosphate and muriate or sulfate of potash will be helpful.

Cranberries.

The cranberry thrives better at the outset, even on certain very acid soils, than after its acidity has been lessened by liming. If more nitrogen is needed than that naturally available from the humus of the bog, it is usually recommended that it be applied in small quantities, as nitrate of soda or preferably as nitrate of potash, provided the bog is already fairly dry and is likely to remain so; but if wet, sulfate of ammonia may be better The chief need of the cranberry vine is usually phosphoric acid and potash. The phosphoric acid for top-dressing may be in superphosphate, but if applied just before the plants are set one may employ bone-meal, or, if on very acid peat or muck soil, even raw rock phosphate.

In case spring applications of fertilizer are made, it must not be expected that they will always affect the cranberry yield of that particular season as much as the yield of the crop which follows. Such applications should ordinarily be made after the water is drawn off and the land has dried out to a reasonable extent. It is often helpful to apply fertilizer just after the cranberry crop is harvested, but late spring applications develop stronger vines for the next season.

Pineapples.

The requirements of the pineapple crop vary widely, dependent upon the rainfall and soil conditions. Where the winter season is likely to be fairly cold, nitrogenous fertilizers should not be applied in the autumn, for otherwise injury from frost may follow. Nevertheless, potash salts have sometimes been used at that time with good effect. On certain acid soils, liming is necessary at fairly frequent intervals in order to bring out the best effect of superphosphates. If lime is not used, bone-meal or basic slag meal may sometimes be preferable to superphosphate as sources of phosphoric acid. From one and three-fourths to two tons of fertilizer an acre, annually, have been recommended for pineapples by the Agricultural Experiment Station of Florida. It is said that the fertilizer should contain 5 per cent of nitrogen, 4 per cent of available phosphoric acid and 10 per cent of potash, in order to meet the conditions in that state. During the first year and a half the applications of fertilizer are made four times a year, but after this period of time is passed, the first application of the year is made either in February or March, and the second after cutting the summer crop. It is obvious that this rule might require modifications on other soil and also as influenced by different climatic or other local conditions.

Table beets, mangels, sugar beets and Swiss chard.

These plants are among the vegetables most in need of liming. Certain of them also have much greater ability than the cabbage and turnip to appropriate from the soil the required supply of phosphoric acid, for beets have been found to yield fair crops where cabbage plants, on account of a lack of available phosphates, failed to develop salable heads.

These plants are able to profit to a considerable extent, as concerns physiological functions, by the soda of nitrate of soda, provided the supply of potash is insufficient, yet it is unwise to limit the supply of potash intentionally, in order to bring out this action, for if this is done the net loss in crop due to insufficient potash may more than offset the advantage of attempting to make the soda fully effective.

All of these plants and many others take up, in varying degrees, considerable more mineral matter than is represented by the sum of the minimum requirements, as determined for each essential ingredient in the presence of an abundance of all of the others. If, therefore, the fertilizer contains soda, it will be taken up in considerable amounts by the plant to satisfy this "luxury" or "excess" consumption in conjunction with the potash physiologically necessary to the plant. Thus the extra potash which would otherwise be taken up to satisfy this excess in the mineral requirement is conserved in the soil for future crops. The use of nitrate of soda, therefore, as one of the ingredients of a fertilizer for these crops, results in insuring the crop against a shortage of potash and prevents the plants from taking up an unnecessary excess of potash, provided an abundance is already present in the soil or is supplied in the fertilizer.

In Europe, beets of all kinds, and especially mangels, have been found to respond very favorably to nitrate of soda in comparison with the results with sulfate of ammonia, yet with certain cereals the yields, under similar conditions, have been larger with the latter. Notwithstanding this favorable action of nitrate of soda on these crops, it is so subject to loss by leaching that it is often better on very open soils to use it in conjunction with several other forms of nitrogen, rather than alone. This is especially true in consequence of the frequent occurrence, in certain sections of the country, of very sandy and gravelly soils and especially in view of the long period of growth of the chard, sugar-beets and mangels.

These crops all require generous supplies of nitrogen, a fair amount of available phosphate, and high percentages of potash. In the case of sugar-beets, if grown for their sugar-content, the proper relationship of these fertilizer ingredients to one another is of great importance.

Cabbage, kale, cauliflower, brussels sprouts, turnips and kohlrabi.

These crops are all remarkably helped by liming on soils which are fairly acid. Liming, especially with caustic or slaked lime, has a tendency to lessen the development on these plants and on turnips, of the disease known as "club-foot" and "finger-and-toe."

What has been said of the action of the soda of the nitrate of soda, in connection with beets, is true also to a considerable degree of these crops; nevertheless, when the period of growth is long and the soil is either a heavy silt or clay, or exceptionally open and subject to leaching, a combination of several sources of nitrogen in the fertilizer, is usually preferable. The reference to heavy silt and clay soils is made in consideration of the fact that sodium carbonate is left as a residual product after the plant has taken up the nitric acid of the nitrate of soda; and this sodium carbonate tends to deflocculate such soils and make them stiffer and more difficult to work than before.

Heavy applications of nitrogen are required for all these crops and some of them, as shown at Rothamsted and elsewhere, are more dependent than beets upon generous supplies of soluble and available phosphoric acid. These plants require also large quantities of potash.

The Swedish turnip, or rutabaga, usually responds to liming rather more than the flat turnip, although lime is often very helpful to the latter.

Several of these plants are especially dependent for their quality on rapid growth; hence, the nitrogen and phosphoric acid must be derived, to a large extent, from readily available materials.

One or two experimenters in this country who have grown turnips in pots and boxes claim to have found that the turnip can utilize rather unavailable forms of phosphoric acid, yet these results need further substantiation in the field before their final acceptance, and in the light of the past field evidence, generous fertilizing with soluble phosphates appears to be desirable. These plants, like the group described previously, respond to liberal amounts of potash salts, yet these salts seldom give very satisfactory results unless they are used in conjunction with liberal amounts of superphosphate and nitrogenous fertilizers.

Carrots and chicory.

The carrot is less likely to show benefit from liming than most root crops, and chicory is even subject to injury by lime when carrots are slightly benefited. Owing to their long period of growth the nitrogen supply for these plants should not only include small amounts of nitrates and ammonium salts, but also soluble and insoluble organic nitrogen, in order that some of the nitrogen may be continually at the disposal of the plant throughout the growing season. These plants are dependent upon reasonable supplies of phosphatic manures, and generous amounts of potash are likewise highly essential. The carrot responds in a less degree than mangels, to applications of soda.

Spinach, lettuce, endive and cress.

These plants are all likely to be greatly benefited by liming, even on soils of moderate acidity. Because of the fact that the quality and market value of these plants depends upon their making a rapid growth, large amounts of immediately available plant-food are essential. Some of the nitrogen should be present in the fertilizer in nitrates, some in ammonium salts and some in quickly available organic forms. No attempt should be made to economize unduly in the use of readily available phosphates and potash salts, for the reason that these crops must have ample supplies of both. The growth of early lettuce, and of spring spinach in particular, may often be pushed forward with remarkable rapidity in the early spring by the use of fertilizers containing generous amounts of nitrates. In fact, these crops may be brought to maturity by such means much faster than by the sole employment of farmyard manure, especially if the manure is poor in nitrogen and not thoroughly rotted.

Onions.

The onion will not thrive and mature properly on highly acid soils which are extremely deficient in carbonate of lime. It is often possible, where fairly good crops can still be grown without the use of lime, nevertheless to hasten the maturity of the onion crop from ten days to three weeks, by its employment. A lack of lime is often one of the causes of thick necks and of failure to ripen properly.

Since the onion crop is planted very early in the season, and because of the consequent opportunities for the loss of nitrogen if too large a part of it is applied in nitrates, appropriate proportions of nitrogen in ammonium salts and in suitable organic forms should also be employed in order to insure an adequate supply as needed.

Generous amounts of potash are required by these crops and it is of vital importance to use for the onion a large amount of superphosphate, because of the fact that it, like lime, hastens the maturity and the proper ripening of the crop. It is also equally important not to use such a large amount of nitrogen as to make it out of balance with the potash, and in particular with the phosphoric acid, for if this is done growth will be unduly prolonged, the onions will have thick necks, and they will not ripen satisfactorily nor quickly.

Potatoes.

Fertilizers for potatoes must be very different according to the section of the country in which they are grown. For example, in the North, where the season is short, the nights cold, and where the crop must be hurried along to the utmost, unusually large proportions of nitrates and of ammonium salts are indispensable, whereas in warmer regions, organic sources of nitrogen may be employed more largely, or perhaps in some favorable cases, they may be used exclusively. The potato crop is in need of quite large quantities of nitrogen, ranging usually from forty to ninety pounds an acre.

The percentages of potash required in potato fertilizers should be adjusted more particularly with reference to the locality, and whereas in many of the potato regions of New England 200 pounds of potash (equivalent to 400 pounds of muriate of potash) are considered necessary for each acre, the quantity could be reduced to one-half or even less in certain portions of the Middle West, or it might perhaps in some exceptional cases be omitted altogether.

For several reasons it is important to insure high percentages of soluble and available phosphoric acid in potato fertilizers, since it often becomes the limiting factor in potato-production over large areas of the United States.

The effect of the fertilizers may be somewhat nullified or intensified, according to the choice of seed. In all cases, seed which has heated or which has been exposed to frost, should be avoided. It has also been shown at the Agricultural Experiment Station in Rhode Island that, if other things are equal, seed tubers which are rich in nitrogen will usually give larger crops than those in which the nitrogen-content is low. The advantage of the high nitrogen-content of the tuber becomes magnified in case they are sprouted once or twice before planting. No amount of nitrogen applied in the field appears to be able to offset finally and fully the disadvantage of the tubers with the low nitrogen-content. This doubtless explains the advantage of early dug potatoes, for seed purposes, as compared with those which are allowed to mature, for the former are usually richer in nitrogen.

Asparagus.

Sandy soil is ideally adapted to the growing of asparagus. Nevertheless, whenever it is intended to establish a plantation on land of this character, it is wise to turn under considerable stable manure or else a heavy leguminous crop such as hairy vetch. If this is done, the general soil conditions are rendered much more favorable and the asparagus has a better chance to gain a good foothold. Wherever the land needs liming, some lime should be plowed under and a further application should be made on the surface after plowing. The land should then be thoroughly harrowed or otherwise tilled.

Fine ground bone and basic slag meal have been used for asparagus very successfully when worked into the soil at the outset, although the latter is rather better adapted to it on account of the greater availability of the phosphoric acid and the fact that it contains considerable lime.

Some of the best growers of asparagus, on sandy soils, have found that muriate of potash is a better source of potassium than the sulfate.

In humid regions fertilizers for asparagus should contain a considerable amount of nitrogen in nitrates, though other forms of nitrogen are also particularly to be desired on light soils, such as those usually employed for this crop, because of the danger of the loss of nitrates by leaching. It is obvious that, for top-dressing, superphosphate is preferable to any other form of phosphoric acid, because of its greater solubility. An ideal fertilizer for asparagus should contain superphosphate, potash salts, and high percentages of nitrogen, a part being derived from nitrates, some from ammonium salts, and also some of it from organic sources.

Sandy soils are likely to be very deficient in phosphoric acid; hence, the quantity of this ingredient should be high. The fertilizer should likewise carry a high percentage of potash on sandy soils, excepting in regions in which it is known not to be needed. Although potash is usually the least deficient element in the sandy soils of humid regions, the demand of the asparagus plant on this ingredient of fertilizers is so great as to make its use profitable, whereas on other sandy soils in semi-arid regions, potash might not be required.

Melons.

On soils that are very acid, it is imperative to use considerable quantities of lime for canteloupes and muskmelons. Such soils will, nevertheless, produce good crops of watermelons, even if liming is omitted, and heavy liming with slaked or burned lime may, in some cases, even decrease the yield.

Owing to the fact that these crops are generally grown on light, gravelly or sandy soil, a fertilizer is demanded for humid regions containing a fairly high percentage of nitrogen. This should be represented by nitrates, to a still greater extent by ammonium salts, and a part should be from suitable organic sources. It should also contain a high percentage of soluble and immediately available phosphoric acid and generous amounts of potash in order to bring the crop to maturity as rapidly as possible. Plants of this character which have an extensive amount of foliage, usually require high percentages of potash. Special care should be taken to keep the fertilizer from coming in contact with the seed.

Squashes and pumpkins.

The common summer squash, as well as the Hubbard and crookneck varieties, are less in need of liming than canteloupes or muskmelons. Nevertheless, on very acid soils liming is decidedly helpful. These crops are all heavy feeders on nitrogen, a considerable part of which should be in immediately available nitrates and ammonium salts. Moderately high percentages of soluble and available phosphoric acid are necessary, although the summer squash, at least, responds much less to phosphoric acid and more to potash than the cereals and most other cultivated crops. On this account, the percentage of potash in fertilizers for squashes should be high, excepting, of course, where the soils are already rich in available forms of this ingredient.

Celery.

Celery is a crop that will thrive well on slightly acid soils. Nevertheless, where the acidity is great, liming is very beneficial. The quality of this crop depends very largely upon its making a rapid and steady growth. On this account a constant water-supply is one of the most important features connected with its culture. It is of the highest consequence that celery should have a large supply of nitrogen embracing suitable proportions of nitrate nitrogen, ammonium salts and organic materials. Fair amounts of soluble and available phosphates are desirable, and on the muck or peat soils where this crop is frequently grown, especially large quantities of potash should be employed, since this is the fertilizer ingredient which they lack to the greatest extent. The form of potash usually preferred on such soils is the muriate, although frequently kainit is said to have given excellent results. Either is perhaps preferable to the high-grade sulfate of potash or to the double manure salt.

Cucumbers.

Cucumbers are considerably more in need of liming than squashes. In other respects they should have essentially the same fertilizer treatment. Great care should be taken in connection with squashes and pumpkins, as well as with cucumbers, not to allow the seed to come in close contact with the fertilizer, or, indeed, with soil into which large quantities of fertilizer have been introduced. If fertilizer is used in the hill it is well to have it thoroughly incorporated with the soil. Subsequently, this soil should be covered with fresh earth before the seeds are planted.

Tomatoes.

The tomato will grow quite well even on soils that are distinctly acid. Nevertheless, moderate liming is often helpful. When tomatoes are grown in greenhouses it has been found that very large quantities of lime are helpful, by virtue of lessening the tendency to certain diseases, but the necessity for it is less in the field because of the lower temperatures and less humid conditions.

In order to hasten the ripening of this crop, it is very important to have large quantities of soluble and available phosphoric acid, and abundant potash in the fertilizer. One of the most important features is to have the nitrogen supply so regulated as to bring about at once a rapid and vigorous growth of the plants, but the quantity must not be so great as to prolong the growing period unduly, since this will prevent early ripening; and it is a well-known fact that the early fruit generally sells for a much higher price than that which matures later. Furthermore, a large proportion of the nitrogen should be present as nitrates and ammonium salts which can be readily utilized. It is also desirable to apply the entire amount at the time when the plants are set, or, at least, very shortly afterward, for if successive applications are made at a later date they will result in prolonging the growing period and delay the ripening of the fruit.

Peas and beans.

Peas are usually much more helped by liming than beans. The latter vary widely in their lime requirement as shown by the fact that on a soil so greatly in need of lime that the Golden Wax and Low's Champion (a green-podded variety) will scarcely produce half a crop, the pole Horticultural bean is only slightly benefited, and the lima bean is practically indifferent to it.

Notwithstanding that these plants are capable of assimilating atmospheric nitrogen, it is nevertheless usually desirable, especially when they are grown to be marketed in the green state, to employ a fertilizer containing a small or moderate amount of readily available nitrogen. This will aid in developing a root-system until such a time as the plants can draw their nitrogen supply to a considerable extent from the air.

Peas and beans also require moderate amounts of potash and phosphoric acid, in fact much more than would be the case if they did not grow so rapidly, and hence reach the crop-producing stage in a short interval of time. The common white field bean has been found to require potash more than phosphoric acid, under conditions in which the cereals and the common farm crops showed a greater response to the latter.

H. J. Wheeler.

FÉRULA (old Latin name, perhaps from the verb *to strike;* possibly the stems were anciently used as ferules). *Umbelliferæ.* Giant Fennel. Hardy striking herbs, prized for their spring and early summer foliage.

Stout perennial glabrous usually glaucous thick-rooted herbs, of perhaps 50 species in S. Eu., N. Afr., and W. Asia: lvs. pinnately decompound, the ultimate segms. filiform or small (rarely broadish and dentate): fls. small, in elevated compound many-radiate umbels; petals broad, mostly ovate-acute, the point often inflexed: fr. orbicular or ovate, plano-compressed, membranous-bordered.—The giant fennels are valued for the excessive fineness with which their foliage is cut, and their clusters of perhaps 40–50 umbels of minute yellow fls. borne on stout sts., which rise far above the foliage. In spring the masses of foliage are very refreshing. The bold fl.-sts. make the plants useful for bordering plantations and for stream sides. The ferulas yield gum-ammoniac, galbanum and asafetida. The genus is now held to include Narthex, Scorodosma and Euryangium. These plants are not to be confounded with the true fennels, which belong in Fœniculum. Ferula is closely allied to Peucedanum. The species are difficult to represent in herbaria, and they are confused.

commùnis, Linn. Common Giant Fennel. Robust, 8–12 ft.: lvs. light green, very numerous, forming a fine mound or clump, the segms. linear-setaceous; lf.-sheaths very large: fls. yellow; central umbel on a branch nearly sessile, and the surrounding ones stalked and mostly male. S. Eu. to Syria.—Presumably the *F. gigantèa* of trade lists belongs here, although *F. gigantea,* Fedtsch., of Cent. Asia, is recognized botanically.

Var. **brevifòlia,** Mariz. (*F. brevifòlia,* Link. *F. Línkii,* Webb & Berth. *F. nodiflòra,* Guss.). Ultimate lf.-segms. shorter than in the type. The gum-ammoniac of Morocco comes from this plant. B.M. 8157. See history in Kew Bulletin, 1907, pp. 375–388.

tingitàna, Linn. (*F. sáncta,* Boiss.). Robust, the st. leafy below, paniculate-corymbose above: lvs. triangular-ovate, quarternate pinnatisect, the segms. narrow-oblong and cut: fls. orange, in globose umbels. N. Afr. B.M. 7267.—Long supposed to be the source of gum-ammoniac. Probably not in the trade.

glaùca, Linn. (*F. neapolitàna,* Tenore). Very tall (to 14 ft.), branching: lvs. large, pinnately decompound; segms. flaccid and broad-linear, obtusish and 1-nerved, green above and glaucous beneath: bracts at base of peduncles membranaceous, oblong, deciduous: fls. yellow, in many umbels. S. France to Dalmatia. G.C. III. 32:441, 442.

F. Assafœ́tida, Linn. (Assafœtida disgunensis, Kaempf. Scorodosma fœtidum, Bunge). St. 6–12 ft., very stout and much-branched: lvs. puberulous and minutely glandular or somewhat tomentose, the radical ones large and ternatisect with segms. oblong-lanceolate and obtuse: umbels on fleshy peduncles, 20–30-rayed, the fls. yellow. S. W. Asia. G.C. III. 32:443. An evil-smelling plant, one source of the drug asafetida.—*F. Nárthex,* Boiss. (Narthex Asafœtida, Falconer). St. 6–8 ft., with large sheaths: lvs. pubescent when young, 1–2 ft. long, ovate, the segms. either entire or irregularly serrate. S. W. Asia. B.M. 5168. A source of asafetida. A specimen described in G. F. 3, p. 523, required 16 years to attain sufficient strength to bloom.

L. H. B.

FESTÙCA (ancient Latin name for a kind of grass). *Gramíneæ.* Fescue-Grass. Annual or perennial grasses grown for ornament or as pasture grasses.

Blades narrow: infl. few-fld., paniculate; spikelets 2- to several-fld.; lemmas firm, rounded on the back, usually acute or awned from the tip.—Species about 100, in the temperate and cooler parts of the world.

A. *Spikelets awnless: blades flat, 2–4 lines wide.*

elàtior, Linn. Tall or Meadow Fescue. One to 3 ft.: spikelets 5–8-fld., about ½in. long. G. 8:179. Gn. 25, p. 428.—Frequently cult. as a meadow or pasture grass. The form called *F. praténsis* is rather smaller and has narrower panicles (Dept. Agric., Div. Agrost. 20:155), sometimes sold under the name *Bromus pratensis,* meadow brome-grass. Eu.

AA. *Spikelets awned: blades narrow involute.*

B. *Sts. loose and decumbent at base.*

rùbra, Linn. Red Fescue. One-half to 2 ft.: base of sts. usually red. Eu.—Occasionally used in mixtures for pastures.

BB. *Sts. in close erect tufts.*

C. *St.-blades flat, the basal blades long and slender.*

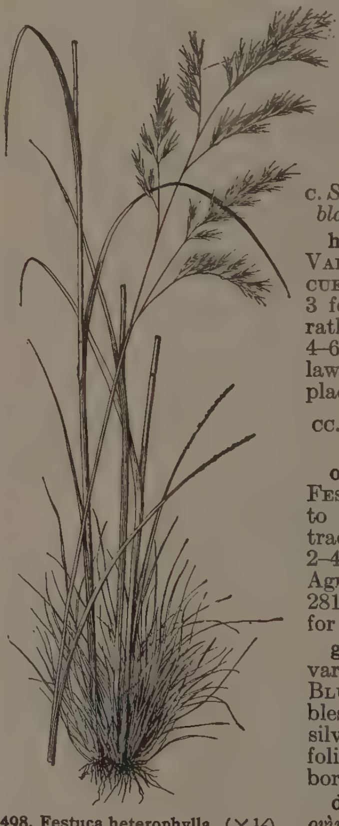
heterophýlla, Lam. Various-leaved Fescue. Fig. 1498. One to 3 feet., slender: panicle rather loose; spikelets 4–6-fld. Eu.—Cult. as a lawn grass in shady places.

CC. *St.- and basal blades involute.*

ovìna, Linn. Sheep's Fescue. Fig. 1499. Six to 20 in.: panicle contracted after flowering, 2–4 in. long. Eu. Dept. Agric., Div. Agrost. 20: 281.—Sown in mixtures for pastures.

glaùca, Lam. (*F. ovìna* var. *glaùca,* Hack.). Blue Fescue. Resembles *F. ovina* but has silvery blue, or glaucous foliage. Eu.—Used for borders.

duriúscula, Linn. (*F. ovìna* var. *duriúscula,*



1498. Festuca heterophylla. (× ½)

Koch). HARD FESCUE. Blades firm and comparatively thick, ½line diam., often rough. Eu.—Pasture mixtures.

vaginàta, Waldst. & Kit. (*F. amethýstina,* Hort., not Linn.). Sheaths and panicles purplish: foliage bluish: panicle 8 in. long. Eu.—Used for ornament.

A. S. HITCHCOCK.

FETTICUS. Another name for *Corn-Salad.*

FEVER-BUSH: *Benzoin.*

FEVERFEW: *Chrysanthemum Parthenium.*

FEVER-TREE: *Pinckneya pubens.*

FEVERWORT: *Triosteum.*

FIBER PLANTS are treated only incidentally in this work, and with particular reference to the horticultural values of the groups to which they belong. See Cyclo. Amer. Agric., Vol. II, p. 281.

FÌCUS (ancient Latin name). *Moràceæ.* The fig, the India rubber plant, the banyan tree and the creeping fig of conservatory walls belong to this vast and natural genus, which has over 600 species scattered through the warmer regions of the world.

Ficus has no near ally of garden value. It is a genus of trees or shrubs, often climbers, with milky juice. In the common fig the lvs. are deeply lobed, but in most of the other species they are entire or else the margin is wavy or has a few teeth or an occasional small lobe. The lvs. are nearly always alternate, *F. hispida* being the only species of those described below which has opposite lvs. The foliage in Ficus varies from leathery to membranous, and is variable in venation, so the veins are very helpful in telling the species apart. Ficus is monœcious or rarely diœcious, the apetalous or sometimes naked minute fls. being borne inside a hollow more or less closed receptacle; stamens 1–3, with short and united filaments; pistillate fls. with 1-celled sessile ovary, ripening into an achene that is buried in the receptacle. What the horticulturist calls the fig, or fruit, is the fleshy receptacle, while the fruit of the botanist is the seed inside (Fig. 1500). In the following account, fruit is used instead of receptacle.

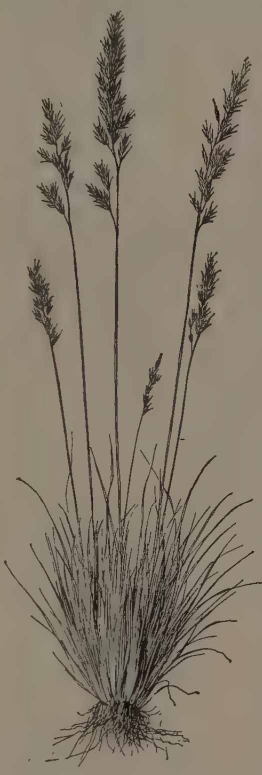
The fertilization or caprification of the fig is one of the most interesting and complicated chapters in natural history, and is of great practical importance. See *Fig,* where the culture of *F. Carica* is discussed.

The most important ornamental plant in the genus is the India rubber plant (*F. elastica*), which ranks amongst the most popular foliage plants for home use indoors. This is not the most important rubber-producing plant, both *Hevea brasiliensis* and *Castilla elastica* being producers of more and finer rubber.

The creeping fig (*F. pumila,* better known as *F. repens* or *F. stipulata*) is one of the commonest and best climbers for covering conservatory walls. It clings close and makes a dense mat of foliage, which is about as dark in color as the English ivy. The plant has been cultivated since 1771, but within the last half-century has come to be recognized as the best plant for its special purpose. Once in a long while it fruits in conservatories, and the fruiting branches are very unlike the barren ones. They stand out from the conservatory wall instead of lying flat and close. The leaves of the barren branches are less than an inch long and heart-shaped, with one side longer than the other at the base and a very short petiole; the leaves of fruiting branches are 2 to 3 inches long, elliptic-oblong, narrowed at the base, and with a petiole sometimes ½ inch long (Fig. 1501).

Among the many wonders of the genus Ficus are the epiphytal habit of some, the huge spread of the banyan tree (*F. benghalensis*), and the fact that some species ripen their fruits under ground. Some of the tallest tropical trees are members of this genus, and often they begin life by climbing upon other trees. The ficus often overtops and outlives the other tree, which may be seen in every stage of decay, or may have entirely disappeared, leaving the giant climber twined spirally around a great hollow cylinder. The banyan tree sends down some of its branches (or aërial roots) into the soil, these take root, make new trunks, and eventually produce a great forest, in which it is impossible to tell the original trunk. The banyan in the botanic gardens at Calcutta sprang from a seed probably dropped by a passing bird into the crown of a date palm a little more than a century ago. The main trunk not many years ago, was 42 feet in circumference, with 232 additional trunks, many of them 8 to 10 feet in circumference, and the branches extend over an area 850 feet in circumference, forming a dense evergreen canopy through which sunlight never penetrates. The banyan under which Alexander camped, and which is said to have sheltered 7,000 men, now measures 2,000 ft. in circumference and has 3,000 trunks. Other species have the same method of propagation, but *F. benghalensis* is the most famous.

The various species are cultivated both indoors northward and as shade and fruit trees in Florida and California. In this country the most important commercially is the fig, *Ficus Carica,* now widely grown in California. For the botanical treatment of this difficult genus recourse has been had to King's "The species of the Indo-Malayan and Chinese countries" in Ann. Bot. Gard. Calcutta 1:185 pp. + 232 plates, 1888, and wherever possible below reference is made to the splendid illustrations of that work, thus, K. 130.= King, plate 130. For the African species the recent treatment of Mildbraed and Burret on Die afrikanischen Arten der Gattung Ficus. Engler's Bot. Jahrb. 46:163–269 (1911), has been consulted.



1499. Festuca ovina. (×⅓)

The cultivation of Ficus elastica. (H. A. Siebrecht.)

The rubber plant (*Ficus elastica*) which is known all over this country, is perhaps the most popular and satisfactory house plant that has ever been cultivated. It is a plant for the million. Some florists have several houses especially devoted to the propagation and cultivation of this tough and thrifty plant. There are also thousands upon thousands of young plants or rooted cuttings from thumb-pots imported into this country, especially from Belgium and Holland, for marketing every spring. It is estimated that from 80,000 to 100,000 rubber plants are sold in America in a single year. There are several varieties of the rubber plant, but the true *Ficus elastica* is the best, both for growing and for selling. It can be easily told from the smaller-leaved variety, which is smaller and lighter colored in all its parts, the stem being smoother, and the sheath that covers the young leaves lacking the brown tint, which often runs into a bright Indian red.

The method of propagating now popular in America employs old bushy stock-plants, either in pots or tubs, or planted out into a bed where the night temperature can be kept from 60° to 75° F. As soon as the young shoots are 5 to 6 inches long they are operated upon. An incision is made at the place where it is intended to root the young plant, cutting upward on a slant midway between two eyes, making the cut anywhere from 1 to 2 inches long, according to the thickness and length of the young shoot or branch. A small wedge, as a piece of match, is then inserted to keep the cut open. A large handful of clean, damp, well-prepared moss is then placed around the branch to cover the cut and is tied moderately firm with twine or raffia. Some use a small piece of charcoal for a wedge in the cut; others coat the two cuts with a mixture of charcoal dust and lime. The latter practice is beneficial in that it expedites the callusing of the cuts and the rooting of the young plant after being cut and mossed. The moss should be kept constantly moist, and the higher the temperature, within reasonable limits, the quicker the rooting process goes on. The roots of the young plant usually appear on the outside of the oval-shaped bunch of moss. A complete cut can then be made below the moss and the young plant potted. The smaller the pot at first the better. The leaves of the young plants should be tied up in order that they may not be injured by coming in contact with one another or by lying flat on the pots. The young plants now require a gentle bottom heat and frequent syringing,—a dozen times on clear days. As soon as the young plants are taken from the stock-plant, a little wax should be put on the end of the cut to prevent the milky sap from escaping. The best time of the year to propagate and root ficus is from the first of January to May. The European growers never start much before the Christmas holidays; and from then until spring they make all their cuttings.

The older method of propagating rubber plants is still the favorite one abroad; it employs single-eye cuttings. Sometimes, if the branches are very thick, only one-half the stem is taken with the eye and a single leaf, the leaf being curled up and tied with raffia, and the small piece with the eye set into the propagating-bed. This is a bed of sharp sand, or sometimes of sand and chopped sphagnum moss or fine cocoa-fiber. Frequently the single-eye cuttings are put at once into the smallest-sized thumb-pot, with a mixture of very finely ground potsherd and charcoal filling about one-half the pot, and either soil or sand for the remainder. A small stick is used to hold the leaf upright. These pots are plunged into the propagating-benches in either sand, moss or fiber, and a steady bottom heat of 75° to 80° is applied and kept up until the plants are rooted. As a rule, such beds are inclosed in a glasshouse, in order to keep about them a close, warm and moist atmosphere. Only ventilation enough to permit the moisture caused by the evaporation to escape is allowed on these beds. In this country, propagation by the first described method can be continued nearly all the year round. From experience of both methods, the writer can say that the top-cutting and mossing process is better by far, especially where plenty of stock plants can be maintained.

1500. Young figs. Showing how they arise from the axis of the leaves.

After being shifted from the smaller-sized pots into 3- or 4-inch pots, the young plants will stand a great deal of liquid manure as soon as they are rooted through or become somewhat pot-bound. Many propagators plant out the young plants from 3- and 4-inch pots into coldframes after the middle of May, or when all danger of night frost is past. They do very well in the bright, hot, open sun, but must receive plenty of water. After being planted out in frames, they should be potted not later than September, and for early marketing as early as August. The plan of planting out and potting in the later part of summer or early autumn is a very practicable one, as the plants do not suffer so much from the severe heat during the summer.

KEY TO THE SPECIES.

A. *Fr. large, edible: lvs. deeply lobed, deciduous for at least 5 months: plants almost hardy from N. Y. southward.*
  B. *Lvs. wavy-margined or lobed* .... 1. **Carica**
  BB. *Lvs. deeply lobed: fr. roughish* .... 2. **Pseudo-Carica**
AA. *Fr. not usually edible, at least not as the fig is edible: lvs. entire or toothed, but not deeply lobed and not deciduous for such a long time: plants, with exception of F. macrophylla, not hardy, and cult. in greenhouses or outdoors in frostless areas of Fla. and Calif.*
  B. *Habit climbing or trailing, often clinging to walls.*
    C. *Plant a climbing shrub or tree: lvs. about 5 in. long* .... 3. **macrocarpa**
    CC. *Plant a creeping vine: lvs. less than 4 in. long.*
      D. *Lvs. unequally heart-shaped at base*... 4. **pumila**
      DD. *Lvs. only slightly notched at base*..... 5. **radicans**
  BB. *Habit erect or straggling, shrubs or trees; not climbing or trailing.*
    C. *Lvs. usually opposite* .... 6. **hispida**
    CC. *Lvs. always alternate.*
      D. *Foliage variegated* .... 7. **Parcellii**
      DD. *Foliage not variegated, except in a variety of F. elastica.*
        E. *The lvs. cup-shaped* .... 8. **Krishnæ**
        EE. *The lvs. not cup-shaped.*
          F. *Length of lvs. more than 4 times the breadth* .... 9. **Barteri**
          FF. *Length of lvs. less than 3 times the breadth.*
            G. *Form of lvs. fiddle-shaped or banjo-shaped, very large* ....10. **pandurata**
            GG. *Form of lvs. not as above.*
              H. *Lvs. lobed, much as in the native oaks: a shrub* ....11. **quercifolia**
              HH. *Lvs. not so lobed.*
                I. *Primary lateral nerves more than 8 pairs, usually much more.*
                  J. *The primary lateral nerves 50 pairs or more* ....12. **elastica**
                    K. *Sheath rosy, showy: lvs. 4–12 in. long* ....13. **Benjamina**
                    KK. *Sheath inconspicuous: lvs. 2–4½ in. long.*
                  JJ. *The primary lateral nerves less than 50 pairs.*
                    K. *Color of fr. purplish.*
                      L. *Tree 100 ft. or less: lvs. very long-acuminate*....14. **religiosa**
                      LL. *Tree small: lvs. short-acuminate* ....15. **glabella**
                    KK. *Color of fr. not purplish.*

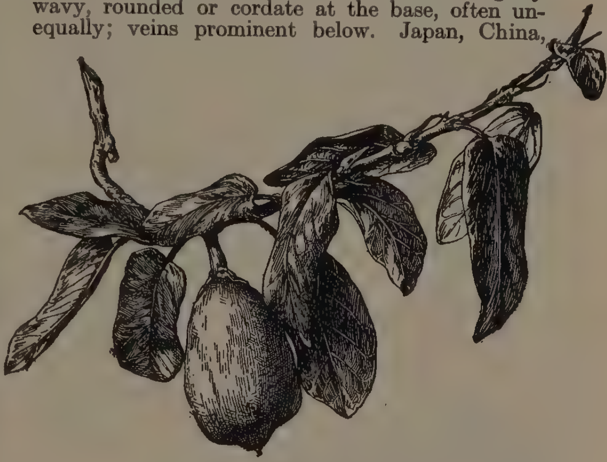
L. *Fr. globose and stalked*..16. **brevifolia**
LL. *Fr. if stalked, pear-shaped, often nearly sessile*.....17. **erecta**
II. *Primary lateral nerves less than 8 pairs.*
J. *The primary veins distinctly bifurcating*........18. **diversifolia**
JJ. *The primary veins not bifurcating*
K. *Stipular sheaths large and showy, rosy*.............19. **macrophylla**
KK. *Stipular sheaths not large and showy.*
L. *Whole plant brown-hairy*.20. **villosa**
LL. *Whole plant not brown-hairy: lvs. often hairy or villous.*
M. *Frs. white or whitish.*
N. *Young lvs. densely woolly beneath; mature lvs. not abruptly acuminate*.........21. **Palmeri**
NN. *Young lvs. not densely woolly; mature lvs. abruptly acuminate*.22. **infectoria**
23. **Cunninghamii**
MM. *Frs. red or yellowish.*
N. *The frs. on scaly leafless branches.*
O. *Lvs. almost orbicular* ....24. **Roxburghii**
OO. *Lvs. ovate to ovate-lanceolate*........25. **glomerata**
NN. *The frs. sessile or short-stalked.*
O. *Young lvs. woolly or rusty.*
P. *Lvs. cordate at base.*
Q. *Diam. of fr. about ½in.*.........26. **rubiginosa**
QQ. *Diam. of fr. 1¼–1½ in.*.......27. **Bellingeri**
PP. *Lvs. not cordate at base*............28. **altissima**
OO. *Young lvs. not woolly or rusty.*
P. *Base of lvs. narrowed.*
Q. *Stipules glabrous.*
R. *Lvs. 2–4 in. long: fr. yellow or reddish*....29. **retusa**
RR. *Lvs. 3–4½ in. long: fr. orange-yellow*.30. **aurea**
QQ. *Stipules not glabrous*........31. **indica**
PP. *Base of lvs. rounded*........32. **benghalensis**

1. **Càrica,** Linn. Figs. 1500, 1505, 1506. Height 15–30 ft.: lvs. 3–5-lobed, the lobes more or less wavy-margined or lobed, and with palmate veins, whereas nearly all species mentioned below are pinnately veined: fr. single, axillary, pear-shaped. Supposed to be a native of Caria, in Asia Minor.—Makes a fine pot-plant, and fruits freely in northern conservatories. For cult. see *Fig.*

2. **Pseùdo-Càrica,** Miq. Resembling the fig of commerce, but the lvs. more deeply cut than in *F. Carica*, 3- or sometimes 5-nerved: fr. axillary, round, roughish. Abyssinia.—Franceschi says of the Calif. cult. specimens "fr. said to contain very much sugar, but so far (1914) it has never come to perfection in Calif., where, however, it is now attracting considerable attention, it having proved to be the very best home for. . . . small wasps (Blastophaga) which are indispensable for the fertilization of the so-called 'Smyrna figs'."

3. **macrocárpa,** Wight. Becomes a large, climbing shrub, very rarely a small tree: lvs. 5 in. long, membranous, broadly ovate; petiole 2–2½ in. long; primary lateral nerves about 3 pairs: fr. 1–2½ in. thick, spotted, globose, in cauline clusters. India. K. 208.—This name was once advertised as a shrub with leathery lvs. The true species is a climbing shrub.

4. **pùmila,** Linn. (*F. stipulàta*, Thunb. *F. rèpens*, Hort., not Rottl.). CREEPING FIG. Fig. 1501. Prostrate or climbing shrub, clinging close to conservatory walls and then flattened: lvs. more or less 2-ranked, on very short petioles, ovate, obtuse, entire or slightly wavy, rounded or cordate at the base, often unequally; veins prominent below. Japan, China, Austral. B.M. 6657. R.H. 1891:448. K. 158. G.C. II. 14:560, 561, 717. H.U. 4, p. 359 (the last two as *F. stipulata*). Var. **mínima** (*F. mínima*, Hort.) has smaller lvs. The species is sometimes used for hanging-baskets.



1501. Ficus pumila, fruiting branch.

5. **radìcans,** Desf. Garden plant, with green, oblong-acuminate lvs. and trailing habit. Imperfectly known. Habitat unknown. Var. **variegàta,** Hort. W. Bull., has lvs. irregularly marked with creamy white, the variegation beginning at the margin. G.C. III. 22:185. A.G. 19:527. R.B. 28:37.—Useful for hanging-baskets. Intro. 1897.

6. **híspida,** Linn. f. (*F. oppositifòlia*, Willd.). Shrub or small tree, all the parts mostly hispid-pubescent: lvs. entire or toothed, opposite, rough-hairy: fr. clustered on old wood or leafy branches, hispid, yellowish. Asia, Trop. Austral. K. 154, 155.—Scarcely cult. in Amer. outside of botanic gardens.

7. **Parcéllii,** Veitch. Lvs. thin, membranous, light green, mottled with cream-white, more or less in the manner of mosaic, oblong-oval, acuminate, dentate. Islands of Pacific. F.S. 22:2273. F.M. 1874:124. A.F. 29:1290. G.C. III. 35:13.—Intro. by Veitch about 1874. A warmhouse shrubby plant; probably the most popular of the variegated forms of Ficus. Readily prop. by cuttings of half-ripened wood placed in sand in brisk bottom heat. Also cult. in S. Calif., where it bears tricolored fr.

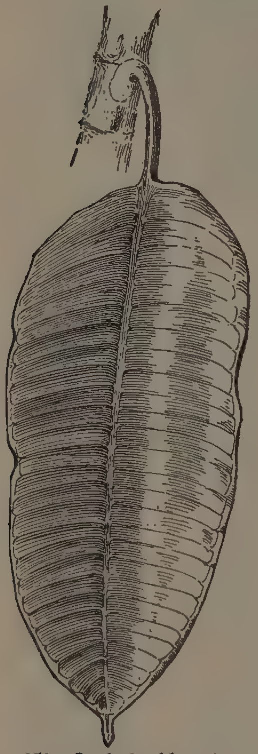
8. **Kríshnæ,** DC. KRISHNA BOR. Small tree with gray bark, the branches puberulent: lvs. cup-shaped, the limb of the cup containing the mid-rib, with 4–5 pairs of lateral nerves: fr. axillary, sessile, solitary or sometimes in pairs, yellow, about ½in. diam. India. B.M. 8092, where there is also an account of the superstitions in regard to the tree among the Indians.—The large showy and extraordinarily cupped lvs. of this most distinct fig will undoubtedly make it popular. Little known as yet in U. S.

9. **Bárteri,** Sprague. A shrub or small tree 6–25 ft. tall in nature, lower in cult., smooth, with thick ridged branches: lvs. petiolate, the blade the narrowest of almost all the figs, 6–14 in. long, and less than 1½ in. wide, bright green above, paler beneath; primary lateral

nerves 16–18 pairs: frs. in axillary clusters of 2–3, almost round, orange-colored when mature, and edible. S. Nigeria.—Little known in U. S. as yet, but worthy of cult.

10. **panduràta**, Hort., not Hance, which is an acuminate-lvd. Chinese fig, apparently not in cult. A showy shrub or tree with distinctive fiddle-shaped or banjo-shaped lvs. frequently a foot long, decidedly emarginate at the apex, cordate at the narrowed base, dark glossy green, the prominent nerves whitish: fr. unknown. G. 28:682. G.C. III. 33:284. Gng. 16:34. Gn. M. 8:268. A.F. 23:239; 26:203.—A showy stove fig now widely grown. Intro. in 1903.

11. **quercifòlia**, Roxbg. The oak-lvd. form is the typical one, but King includes *F. humilis*, Roxbg., in which the lvs. are serrate or nearly entire and not lobed. Lvs. 2–5 in. long, "thickly membranous;" nerves 5–7 pairs; petiole ½–1 in. long: fr. in axillary pairs, egg- or pea-shaped. Burma, Malaya, where it is a shrub. L.B.C. 16:1540. K. 95. (The plant fruiting soon after importation, when 2 ft. high.)—Advertised in 1895, and grown for years at the Montarioso Nurseries. Voss refers this, with many other synonyms, to *F. heterophylla*.



1502. Leaf of rubber plant, Ficus elastica, showing venation. (×¼)

12. **elástica**, Roxbg. (*F. Duvivièri*, Hort., a form with thinner lvs.; otherwise the same). India Rubber Plant. Figs. 1502, 1503. Lvs. 4–12 in. long, shining, leathery, oblong to elliptic, with an abrupt, dull point; nerves parallel, running at nearly right angles from midrib to margin: fr. in pairs, sessile, in axils of fallen lvs., covered at first by a hodded involucre, when ripe greenish yellow, ½in. long. Damp forests of Trop. Asia. G.F. 2:547. H.U. 6, p. 108. K. 54.—Becomes 100 ft. high in tropics, but becomes unsightly under glass at 8 or 10 ft. Cult. plants mostly have a single st., but there is a growing demand for compact and branching plants. Var. **variegàta** (var. *aùrea*, Hort.) is much less popular. Lvs. creamy white or yellow near the edges. Liable to fungous diseases. This species is also grown S. as a shade tree. The nervation is very characteristic. So, also, is the handsome rosy sheath which incloses the young lvs., and which soon drops off. This is regarded as a stipule of exceptionally great size.

13. **Benjamìna**, Linn. A rather unimportant tree horticulturally, with small lvs., and smooth throughout: lvs. thin, not much coriaceous, shining, ovate-elliptic, entire, the apex sharply acuminate, 2–4½ in. long; lateral primary nerves very numerous, freely intermingling near the margins of the lvs.: frs. in pairs, axillary and sessile, smooth and blood-red when ripe. Malayan Penins. K. 52, 83*h*. Var. **comòsa**, Kurz. Fig. 1504. Sepals lanceolate-acuminate rather than spatulate: fr. ¾ in. diam., narrowed at base rather than globose or ovoid.

14. **religiòsa**, Linn. Peepul Tree of the Hindoos. Lvs. ovate-rotund, at the apex produced into a long, linear-lanceolate tail-like appendage; petiole 3–4 in. long; stipules minute: fr. in axillary pairs, sessile, dark purple, ½in. thick. India. Gn. 1, p. 435. K. 67*a*.—Grows 100 ft. high, and the lvs., suspended on their long, flexible petioles, rustle in the slightest breeze. "Quite hardy in S. Calif. but not attaining very large size."—Franceschi.

15. **glabélla**, Blume. A small tree, ultimately glabrous throughout: lvs. petioled, thin, not very leathery, obovate-oblong, acuminate, entire, 2–4 in. long, 3-nerved, and with 8–10 pairs of primary lateral nerves: fr. all lateral, sometimes axillary, usually not so, sessile, or very rarely stalked in cult. specimens, dark purplish, sometimes with yellow dots, less than ½in. diam. Malaya Penins. K. 60.

16. **brevifòlia**, Nutt. (*F. popúlnea*, Willd.). An evergreen tree, sometimes epiphytic in nature, 10–30 ft.: lvs. thin and only slightly leathery, ovate or rarely obovate, 1½–4 in. long, acute at the apex, broad at the base; primary lateral nerves 14–16 pairs: fr. distinctly stalked, yellow when young, ultimately bright red, about ½in. diam., and nearly globose. Fla.—Of little value horticulturally, except for the frs.

1503. Ficus elastica, the rubber plant of florists.

17. **erécta**, Thunb. Extraordinarily variable: shrub to small tree, glabrous, pubescent, or almost strigose: lvs. broadly ovate, obovate or elliptic (lanceolate in var. *Sieboldii*), entire or with here and there a lobe, or rather coarsely dentate above the middle: fr. single or in pairs, peduncled or subsessile, and either globose and not stalked or pear-shaped and long-stalked. Himalayas, China, Japan. B. M. 7550 (where the lvs. look rather leathery). K. 178.—Procurable through dealers in Japanese plants.

18. **diversifòlia**, Blume (*F. lutéscens*, Hort.). Mistletoe Fig. A smooth shrub or small tree with short-stalked or sessile lvs.: lvs. broadly obovate, the much-narrowed base glandular, 1–3 in. long, midrib branched once or twice, glandular at the joints: fr. axillary, solitary, or rarely in pairs, always stalked, dull yellow or reddish when ripe. India and Malay Penins. R.B. 30:156. K. 174.—The small lvs. and usually solitary fr. suggest the mistletoe, and in nature the plant is often an epiphyte.

19. **macrophýlla**, Desf. Moreton Bay Fig. Lvs. 6–10 in. long, 3–4 in. wide; stipules 2–4 in. long: fr. nearly globular, 9–12 lines thick, axillary, in 3's or 4's, on short, thick peduncles. Austral.—Much planted in S. and Cent. Calif., where, however, it does not perfect seed. F. von Mueller says it is perhaps the grandest of Australian avenue trees. Ernest Braunton claims for this species partial or perhaps complete immunity from frost. He cites a specimen in Calif. which leaved out after a heavy frost and is still (1914) healthy after more than a year has elapsed since the frost.

20. **villòsa,** Blume. A straggling shrub, the whole plant brown-hairy: lvs. thick and leathery, petioled, oblong-ovate, sharply acuminate, the base cordate, 3–5-nerved at the base, the primary lateral nerves 5–6 pairs, 5–6 in. long: fr. short-stalked, in axillary clusters. Malaya. K. 172.—A good stove climber, but little known in Amer.

21. **Pálmeri,** Wats. Tree, 8–12 ft. high, branching near the ground: lvs. 3 in. long, 2–2½ in. wide; petiole 1 in. long: fr. in pairs, axillary, globose, ½in. thick, white, according to Franceschi needing much heat to develop. Discovered on San Pedro Martin Isl., N. W. Mex., 1887.—Perhaps the best adapted to severely hot and dry places. Franceschi says it attains 30 ft.

22. **infectòria,** Roxbg. A low tree, all the parts smooth; often deciduous for some weeks at a time: lvs. 3½–5 in. long; nerves 5–7 pairs, not prominent: fr. in axillary pairs, sessile, globose, ¼in. thick, whitish, flushed and dotted. Trop. Asia, Malaya. K. 76–79. —Grows 60 ft. high, and is one of the best shade trees.

1504. Ficus Benjamina var. comosa.

23. **Cúnninghamii,** Miq. A large tree, resembling *F. infectoria* and differing only in the form and acumination of the lf. from that species: in *F. infectoria* the primary lateral nerves are easily detected; in *F. Cunninghamii* they are fine and so much intermingled as to be almost indistinguishable. Austral.—Recommended as a shade tree for extreme S. Fla. by Reasoner Bros. Cult. in temperate house northward. Deciduous for several months each year.

24. **Róxburghii,** Wall. A low tree, 10–20 ft.: lvs. broadly-ovate or rounded, 5–15 in. long, 4½–12 in. broad, sometimes cordate at the base; primary lateral nerves 5–7 pairs, prominent on both sides: fr. 2 in. diam. on short leafless cauline branchlets, reddish. India. K. 211.—The lvs. are frequently almost orbicular; very ornamental.

25. **glomeràta,** Roxbg. Cluster Fig. Lvs. 4–7 in. long; nerves 4–6 pairs: fr. clustered on leafless, scaly branches, pear- or top-shaped, 1¼ in. thick, reddish. India, Burma. K. 218, 219.—"A quick-growing, evergreen shade tree."—Reasoner. "A dense shade tree: lvs. have a peculiar metallic luster and are deciduous for a short time at the end of winter: small frs., much relished by cattle and children but dry and woody." —Franceschi.

26. **rubiginòsa,** Desf. (*F. austràlis,* Willd.). Lvs. leathery, rounded or cordate at base, notched at tip: fr. mostly in pairs, globular, 5–6 lines thick, usually warty. Austral., where it throws out aërial roots like the banyan tree. B.M. 2939.—The rusty color is a beautiful feature. Voss considers this a form of *F. elastica.*

27. **Béllingeri,** C. Moore. Tall glabrous tree: lvs. ovate, sharp-pointed, leathery, 5–6 in. long, dark green and shining above, light green and paler underneath; petioles 2–3 in. long: fr. 1¼–1¾ in. diam., marked with small scattered warts. New S. Wales.—According to Franceschi it grows faster than *F. rubiginosa,* its nearest relative. Rare in cult., but advertised in 1914.

28. **altíssima,** Blume. A tall tree with only a few aërial roots, when mature wholly glabrous: lvs. petiolate, thick and leathery, broadly ovate, sometimes inequilateral, but not cordate, shining, 3–5-nerved and with 5–6 pairs of lateral primary nerves, 4–7 in. long: fr. axillary, sessile, in pairs, yellowish when ripe. India. K. 30, 30*a*.—Said by an American dealer to resemble *F. pandurata,* but this must be an error. Franceschi says it is taller-growing and finer than *F. elastica.*

29. **retùsa,** Linn. (*F. nítida,* Thunb., and Hort., not Blume). Lvs. 2–4 in. long; nerves 5 or 6 pairs; petiole 3–6 lines long: fr. sessile, in pairs, axillary, 4 lines thick, yellow or reddish. Trop. Asia, Malaya. K. 61, 62.—A large evergreen tree with a few aërial roots.

30. **aùrea,** Nutt. Branches pale, smooth, furrowed: lvs. 3–4 in. long, smooth, oblong, entire, narrowed but obtuse at each end, stout-petioled: fr. orange-yellow, globose, 4 lines thick. S. Fla.—Reasoner says it is a handsome decorative plant for the florist, and that it grows 60 ft. high. Chapman describes it as a small tree; he says nothing about stipules. Too tender for outdoor cult. in S. Calif.

31. **índica,** Linn. Not the banyan tree. Glabrous throughout, except stipules: lvs. 4–7 in. long; nerves about 4–6 pairs, not very prominent; petiole 4–12 lines long; stipules 6–9 lines long: fr. in crowded pairs, sessile, globose, smooth, yellowish red, 4 lines thick. Trop. Asia, Malaya. K. 45.—This species is greatly confused in botanical literature with *F. benghalensis,* but *F. indica* does not take root from its branches, as does the banyan tree. In recent writings, *F. indica* is often given as a synonym of *F. benghalensis,* but the distinctions here given are those made by King, in Flora Brit. India 5:499 (1890). Tree grows 50 ft. high.

32. **benghalénsis,** Linn. Banyan Tree. Also written *bengalensis.* Young parts softly pubescent: nerves prominent; petiole 6–18 lines long; stipules 9–12 lines long: fr. in pairs, sessile, globose, puberulous, red, about the size of a small cherry. Trop. Afr., India.—A tree, 70–100 ft. high, rooting from the branches, thus forming accessory trunks and extending the growth of the tree indefinitely. For an explanation of the confusion between *F. benghalensis* and *F. indica,* see Hooker's Flora Brit. India 5:499, 500. K. 13.—There are vigorous specimens growing outdoors at Miami, Fla.

F. Afzélii, Don, is a plant from S. Afr., never described by Don. The plant in the trade is said to be F. eriobotroides. Once advertised for indoor ornament.—*F. carnòsa,* Hort. Advertised 1895 for indoors.—*F. Chauvièrii,* Hort. In Eu. this is said to be second only to F. elastica. Franceschi says it has broader and more oval lvs., large red figs, not edible, and comes from New Caledonia, where it attains 60 ft. J. D. Eisele says that it has oval lvs. with creamy white veins, is strong-growing, and should be valuable for subtropical gardening. The name is unknown in botanical literature. A plant cult. at N. Y. Bot. Gard. as this species has orange fr.—*F. Coòperi,* Hort., is cult. indoors from Trop. Amer. Advertised 1895. The name is unknown in botanical literature. G. 1:757.—*F. Dryepóndtia,* Hort., is a striking shrub with long-stalked lvs. that are silvery green above and dark purple beneath. Probably not a Ficus. R. B. 32, p. 85. Said to be a native of Afr.—*F. eetveldiàna,* Hort., is a species "with large broadly oval lvs. and with the veins and nerves colored," something as in Caladium. The name is unknown in botanical literature. G.C. III. 28:303.—*F. criobotroides,* Kunth & Bouché. Habitat unknown. See F. Afzelii.—*F. falcàta,* Miq., is cult. but not advertised. A creeper, with lvs. often of 2 forms, leathery, tesselately dotted and colored beneath. It is a form of F. punctata, with lvs. oblong or subrhomboid, obtuse, not tapering below. India.—*F. Luciànii,* Hort., "has large lvs." Intro. 1900. Otherwise unknown.—*F. lùcida,* Dry. From India, but not described in Flora of British India. Advertised 1893 for indoors.—*F. maculàta,* Linn., described by Franceschi (1914) as with lvs. "large, oval, light green, not glossy. Cochin-China." must be some other plant than the true F. maculata, which is a serrate-lvd. fig from Santo Domingo.—*F. nemoràlis,* Wall., is a "small tree or bush" with smooth, petioled lvs. which are 3-nerved and dark-colored beneath: fr. smooth axillary, about ½in. diam. India. K. 206, 207.—There are many forms.—*F. prínceps,* Kunth & Bouché. Brazil. Cult. by Franceschi, who says it grows 60 ft. high and has magnificent foliage, which is bronze and copper-colored when young.—*F. pyrifòlia* may be F. Benjamina, F. erecta, F. Fontanesii, or F. rubra. The name is advertised by Yokohama Nursery Co., who also advertise F. erecta.—*F. rugòsa* is a trade name for some fig as yet undeterminable. The true F. rugosa, Don, is perhaps a Trop. African species, but was not characterized by Don, and the status of the name is uncertain.—*F. Syco-*

mòrus, Linn. (Sycomorus antiquorum, Gasp.), is a tree with petioled, ovate, entire 8–10-ribbed lvs. which are deciduous for some months each year: fls. greenish or yellowish in pedunculate racemes: fr. small but abundant, extensively used for food: it is a branching tree 30–40 ft. high, the lvs. smaller than those of the fig, more or less angular or even lobed. Egypt and Syria; the sycamore of the Bible; Pharaoh's fig. Intro. in U. S., but not in the trade.—*F. vásta*, Hort.=F. populifolia, an Abyssinian species not in cult. —*F. Wéndlandii* has lvs. "10–12 in. long by 8–10 in. wide, of a dark green color, and light green ribs and veins." Its habitat and fr. are unknown.—*F. Wrìghtii*, Benth., a creeping or climbing fig not cult. in Amer. outside of fanciers' collections: lvs. 3–4 in. long, wedge-shaped, 3-nerved. Probably=F. foveolata, Wall. China.

N. Taylor.†

FIG (Plate XLII) is *Ficus Carica*, a native of Asia. It is a warm-temperate fruit, although it will stand 10° to 20° of frost under favorable conditions. It was early introduced into North America, but until recent years it has been little grown commercially. It has been known to fruit in the open in Michigan without other protection than a high board fence inclosure, but usually, if grown north of Philadelphia, the plants are lifted in early November, with good balls of earth, kept in a dryish cellar over winter, and planted out the next spring. From Philadelphia to the Carolinas it may be bent to the ground and covered with earth or pine boughs. The fruit is borne on the young wood, and often on young trees. This fruit is really a hollow pear-shaped receptacle with many minute seeds (botanically fruits) on the inside; it grows like a branch from the side of the shoot. Inferior, run-wild forms are frequent in the southern states, where they are sometimes called "old man and woman" by the negroes. Figs may be grown under glass, being planted permanently in a border after the manner of hothouse grapes. They usually bear better if the branches are trained more or less horizontally. Two or more crops may be expected in one year under glass. Eastern nurserymen sell fig trees. As early as 1833 Kenrick ("New American Orchardist") described 23 varieties. Popular varieties for amateur cultivation in the East are Turkey, White Genoa, Black Ischia and Celeste. In order to facilitate the ripening of the fruit in cool climates or under glass, it is a custom to dress the surface of the nearly full-grown figs with sweet oil. As a dessert fruit figs are usually eaten in the fresh state, in which condition they are scarcely known to people in cool climates. They are also cooked, and preserved. The commerical fig is the dried fruit.

The fig is propagated very easily from hardwood cuttings, as grapes are. Take cuttings in the fall, removing just below a bud. If wood is scarce, single-eye cuttings may be used, being started preferably in a frame. From cuttings, bearing plants may be expected in two to four years. New varieties are obtained from seeds.

Various fruit books give directions for the growing of figs. Publications in California and of the United States Department of Agriculture discuss them. But the only independent American writing seems to be James T. Worthington's "Manual of Fig-Culture in the Northern and Middle States," Chillicothe, Ohio, 1869. Although regularly copyrighted, it is a pamphlet of only ten pages. It recommends the laying down of the trees in late fall and covering them with earth. This practice gave better results than covering with other material, or carrying the trees over winter in cellars, either in tubs or transplanted from the open (p. 1552). L. H. B.

Figs in the southeastern and Gulf states.

In the southeastern Atlantic and Gulf states the fig has been cultivated since the days of the earliest settlements. The exact time of introduction and indeed the exact origin of many of the more important varieties are unknown. For many years the trees, or more properly bushes, found a place as dooryard or garden plants, and to this day some of the finest specimens are to be found near the shelter of buildings in country, town or village. The fruit was used by the owners of the bushes and the surplus found its way into the local market.

Within the last ten to twenty years, attention has been given to the fig as a commercial fruit and it has found a place as an orchard fruit in many localities. Its culture may be said to extend from Norfolk, Virginia, southward along the Atlantic coast, and around the Gulf of Mexico into Texas. In proximity to the water it is grown without protection, but inland, particularly in the northern limits of its range, the bushes are protected during the winter months, by bending them down and covering with boards, straw, heavy paper, in fact anything that will cover them. With some care in protecting the plants by laying them down and covering in winter, the fig is grown beyond the region in which it has a place as an orchard fruit. Most of the orchard plantings have been made in close proximity to the ocean or gulf.

The propagation of the fig in this region is almost entirely by cuttings made from well-ripened wood and planted during winter or in early spring. The hardened wood from old bearing trees gives the most satisfactory results. The cuttings should be 4 to 5 inches long, and cut through the nodes. In planting, the cuttings are set with the upper ends level with the surface of the earth.

Soils best adapted to the growing of the fig are clay soils, or heavy soils, which are or may be kept uniformly moist. No greater mistake can be made than to attempt the culture of the fig in light sandy soils, more or less deficient in moisture in the lower South. Under these conditions, the nematode (root-knot) works serious damage to the roots of the trees and the planting soon dies out. But on heavy soils, the nematodes are not able to work such havoc and the fig thrives in spite of their limited attacks. On light soils, the fig may be grown in the well-packed earth of yards or planted against buildings where the roots may find their way into the soil beneath the buildings, where the nematode has been starved out for lack of food plants. The shaded condition of the soil is also beneficial. It is doubtful whether a successful planting can be made on any large scale on light soils in the lower South for the reasons just indicated

Varieties.

The varieties which may be grown successfully in the area indicated belong to the group which will carry good crops of fruit without pollination. On account of climatic conditions, it is doubtful whether figs of the class requiring caprification can ever be successfully grown.

The more important varieties are the following:

Black Ischia.—Size medium to large; color of skin bluish black, almost entirely covered with delicate bluish bloom; flesh creamy white; quality good. Strong grower, not a heavy bearer but quite hardy. Season late.

Brunswick.—Fruit very large, broadly pear-shaped with short, rather slender stalk; ribs well marked, eye large, open with rosy scales; skin tough, dark brown in color; pulp thick, pink, soft, quality fair. Midseason and late.

Celeste.—Small to medium, pear-shaped, ribbed; violet-colored, sometimes shading purplish brown, covered with bloom about half way up from the neck; stem short, stout; flesh whitish, shading to rose-color at center, firm, juicy, sweet, excellent quality. One of the hardiest varieties of figs, and can be grown far outside of the usual limits of culture; very desirable for canning and preserving. Season early.

White Ischia.—Fruit of medium size, turbinate; skin greenish yellow; pulp rosy, red, soft, melting; quality rich, sweet; a variety of high quality. Very productive. Season late.

Lemon.—Fruit medium to large, flattened, faintly

XLII. A young Celeste fig tree, as grown in Georgia.

ribbed, light yellowish green; stem short, stout; flesh white, sweet, rather soft; quality fair to good. Vigorous and prolific. Early.

Magnolia.—Fruit of large size; amber-colored; flesh pinkish amber, handsome. Vigorous grower; prolific; excellent for canning. Midseason and late.

Turkey (*Brown Turkey*).—Size medium to large; broadly pear-shaped, with short, thick stalk; ribs few in number; color coppery brown; flesh white, or slightly amber-colored, shading to pink about the seeds; flesh solid, excellent quality. It is very hardy and prolific. Midseason and late.

Of the varieties just described, the more important commercial sorts are Celeste, Turkey, Brunswick and Magnolia.

Magnolia is the favorite variety along the coast in Texas from Beaumont southward. In the eastern Atlantic states it is not so favorably regarded, as the fruit splits and sours on the trees during the rainy weather which so often comes when the crop is maturing. It is entirely distinct from the Turkey fig. Turkey or Brown Turkey is very hardy, of dwarf growth and therefore a favorite in the colder sections in which the trees must be protected during winter. Celeste equals Turkey in hardiness, but it is a more robust grower. It is the most commonly planted variety from Beaumont, Texas, eastward, and in the southeastern states should generally be given preference for orchard planting. Brunswick, on account of its large handsome appearance is a desirable variety for the production of fresh fruit for market.

General cultivation.

In setting the fig in orchard, the trees are commonly placed 10 by 15 feet or 12 by 20 feet in thoroughly plowed and pulverized soil. January and February in the lower South are favorite months for planting, but in the colder sections it is usually better to delay planting until after spring opens. While setting the trees, great care should be taken to prevent the roots from becoming dried out. This point must be strongly emphasized, as the character of fig roots is such that they will not stand drying.

It is not best to attempt to train the figs to tree form, but to allow them to develop with three or four trunks. To start them in bush form it is necessary to cut the plants back hard at time of planting. In case of severe weather during winter there is much less danger of losing whole trees if grown with several stems or trunks than if grown with single trunks. Subsequent pruning should be done to remove any sprouts or suckers that come up from the ground, to remove dead or injured branches, and to shape the form of the trees during the first few seasons. Branches that have to be removed for any cause should be cut back entirely rather than to stubs. The fig will not stand severe pruning year after year, such as has sometimes been attempted, and it is best to prune as little as possible to keep the trees in good shape.

As the fig is a shallow-rooted tree, deep tillage is impossible. The orchard should not be plowed and implements for shallow cultivation only should be used. There is no better tillage tool than an ordinary hoe, but its use is too expensive on large plantings. It may, however, be used in the garden plot. Cultivation should begin in spring just in advance of the starting of growth and should continue at weekly or ten-day intervals until about July 1. Cover-crops of cowpeas or beggarweed should then cover the ground until autumn. In the handling of plantings of the later-ripening sorts, cultivation should be continued later in the season, and a winter cover-crop used instead of a summer one. Stable manure and commercial fertilizer should be used liberally to supply the necessary plant-food.

A considerable amount of fruit can be and is handled in the markets as fresh fruit. It should be carefully cut from the trees early in the morning, selecting only well-colored but firm fruit, packed in strawberry carriers and shipped by express. When the work is properly handled in this way, its marketing presents no serious difficulties within a radius of 100 miles or so in the lower South and even greater distances in the northern area of its possible culture. By far the greater quantity of fruit is used by the canneries in the manufacture of preserved figs. A very delicious product is manufactured in the lower South, and meets with a ready sale.

H. Harold Hume.

The fig in California.

The fig, as grown in California at the present time, illustrates, perhaps more than any other fruit, the difficulties that arise in the course of the introduction of any new and highly specialized industry. Years of time and the united labors of many persons have at last resulted in the permanent establishment of fig-culture on a large scale in some parts of California. The successive steps by which this has been accomplished form one of the most remarkable chapters in our horticultural history.

The edible cultivated fig is a native of southwestern Asia and undoubtedly ranks as one of the most ancient, beautiful and valuable of all fruit trees, forming a large part of the daily food of the people in those countries in which it thrives. The common name fig comes from *Ficus*, and that from the Hebrew "feg." The importation of figs, dried, canned or preserved, into regions unsuited to their growth, forms an immense and increasing group of industries. The literature of the fig, always very large, is receiving continual additions, as new varieties are introduced, as new values are found for the varied products and as its culture is being extended far beyond what were thought, twenty years ago, to be its inflexible climatic limitations.

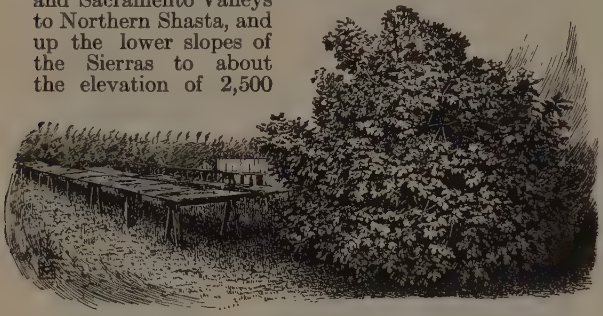
1505. White Adriatic fig.

The botanical varieties of the edible fig (*Ficus Carica*) as generally recognized include the following: (1) *Ficus Carica* var. *sylvestris*, the all-important wild fig of Asia Minor; (2) *Ficus Carica* var. *smyrniaca;* (3) *Ficus Carica* var. *hortensis;* (4) *Ficus Carica* var. *intermedia.*

The first of these, commonly known as the Capri fig, is not edible, but it was discovered ages ago that the famous little fig-wasp, formerly called *Blastophaga psenes* but now determined as *Blastophaga grossorum,* breeds within it and is able to cross-pollinate the flowers of the invaluable Smyrna fig which otherwise will not perfect fruit. This process is termed "caprification" and is absolutely necessary for the maintenance of the highest grades of commercial orchards. The third of these groups includes all the self-fertilizing table and preserving varieties of the common fig. The fourth variety (*intermedia*) has the ability to mature one crop without cross-pollination, but not a second. The best figs for drying are all of the second class (var. *smyrniaca*) and three crops are the usual thing in average seasons. In fact, nearly all the cultivated figs bear three more or less distinct crops; in many orchards and gardens of California one may gather ripe figs every day from late July until frost and rains destroy the very perishable fruits.

Figs have been cultivated on the Pacific coast for more than two centuries, as it is thought that they were in the Mission gardens at Loreto, Lower California, before 1710. Father Zephyrin's monumental "History of the Franciscan Missions in Calfornia," three volumes of which have now been issued (1913), contains many facts about the first Mission gardens from San Diego to Dolores and Sonoma. The fig was in them all, and was spoken of by the early visitors to California, such as Malaspina, Menzies, Mocino and Vancouver. Santa Clara Mission had rows of very large fig trees before 1792.

At the present time (1913), the fig has become established over almost the entire horticultural area of California, wherever the temperature does not fall below 18° F. It does not thrive where there is much fog or where the summers are cold and windy, but even in such places if somewhat protected by walls or buildings, it matures fruit. When planted close to its climatic limits, a young tree needs special protection the first few years until the wood is mature and the growth less rapid. The fig is most at home in southern California, over the Coast Range Valleys, the San Joaquin and Sacramento Valleys to Northern Shasta, and up the lower slopes of the Sierras to about the elevation of 2,500 feet in central California—to 3,000 feet and upward farther south. Magnificent single trees and stately avenues abound in various places. Many trees now standing have trunks 3 feet in diameter. One in Stanislaus County is 80 feet in height; another in Butte County has rooted from drooping branches until it seems a whole grove. This is the notable General Bidwell tree at Chico (Mission Black variety) which covers a circle of 200 feet in diameter and has long been the pride of the region. Superb fig trees are found in all the old foothill and valley towns of California. A magnificent grove is on the old Thurber farm near Vacaville. Large commercial fig orchards have been planted, especially in Nesuo, Los Angeles, Butte, Santa Barbara, San Bernardino, Tulare, Merced, Sonoma, Placer, San Joaquin and Shasta Counties. The Maslin orchard near Loomis and the Roeding orchard east of Fresno are two of the most famous and successful ones in California. Fresno County now has 220,000 bearing fig trees, and Los Angeles nearly 100,000.



1506. Young fig tree, and fig-drying in open air, California.

Varieties.

There are many horticultural varieties known to the markets and catalogues under innumerable synonyms. Their classification is by shape, color of skin and color of flesh. The shape is round or turbinate in some sorts, pyriform or obovate in others. The skin varies in color in different varieties from green through pale yellow, buff, light brown, reddish brown and purple, to black. The flesh is almost white, opaline, or various shades of red; it can be described as melting, spicy, juicy, coarse or even dry in a few old sorts. The size varies from those hardly as large as a green gage plum to others that sometimes weigh four or five ounces apiece. Eisen, in his useful and thorough monograph on the fig published by the Department of Agriculture (Division of Pomology, Bulletin No. 9, 1901) lists and describes nearly 400 varieties from different parts of the world. Eleven of these are Smyrnas, and twenty are varieties of the Capri or wild fig, differing in season so as to afford a succession and thus increase their value in caprification. Baja California, and Sonora, fine regions for the fig, have produced some varieties of promise, and others have been reported from South Africa, New Zealand, Australia, Tasmania, northern India, Algiers and many other places.

When the earlier California nurserymen began to grow figs, they first secured the Black Mission variety which the padres had brought from Mexico, and the little White Marseilles, which was at Santa Clara and Santa Barbara before the discovery of gold. They also obtained from Ellwanger and Barry, of Rochester, and from Berckmans, of Georgia, between 1860 and 1870, all the varieties then grown in America, principally for pot and greenhouse culture, not more than twenty-five sorts in all, chief among which were the Brown Turkey, Celeste, the Green and Black Ischias and the large Brunswick. Georgia and the Gulf coast were cultivating in gardens these sorts for home use, especially Celeste, which is fine for canning and preserving. There was therefore, much early correspondence between California nurserymen like William B. West, John Rock, Felix Gillet, James Shinn and others, and the fig-growers in the South, whose main drawback was in the frequent summer rains. Almost immediately, however, the Californians began to import trees from France, Italy, Spain, and later began to study the Smyrna fig industries. The catalogues of California nurserymen, by 1880, contained about 150 named varieties—with plenty of duplications, as was natural. The University of California experiment stations, by 1890, had about seventy-five varieties under trial and distributed them with great energy. The late John Rock, one of the most ardent horticulturists of his time in America, made many trips abroad and seldom failed to send back new kinds of figs. The inevitable and essential sifting down continued for over thirty years from 1880 until the nurseries of today list not to exceed thirty varieties. The principal sorts now in general cultivation, besides the very important Smyrna and Capri varieties sent out chiefly by George Roeding of Fresno, are the following:

Adriatic (Grosse Verte).
Agen.
Angelique.
Black Ischia (Black Marseilles; Black Provence; the Reculver of England).
Bourjasotte Blanche.
Brown Turkey.
Brunswick.
Celeste (Celestine)
Col di Signora Nigra.
Dauphine.
Doree.
Drap d'Or.
Du Roi.
Lardaro.
Madeline.
Mission (California Black).
Negro Largo.
Pastiliere.
Pingo de Mel.
Ronde Noire.
Ronde Violette Hative.
Royal Vineyard.
San Pedro (white).
Smyrna (common type).
White Genoa.
White Ischia.
White Marseilles.

A large amount of new experimenting has been done in California with fig varieties by the Bureau of Plant Industry which took up the work so well begun by Hilgard and others at the California Station. Lack of means and a general change of the University policy toward the sub-stations (where the fig orchards were located) led to the abandonment of those useful trials about 1902. Fortunately, the United States Department of Agriculture had become deeply interested in the Smyrna fig problem, and soon established plant gardens in California. Beagles, who has charge of the one near Chico, furnishes the following list of the varieties being tested there in 1912, in addition to a great many seedlings and crosses under numbers and not yet in bearing. The list, as furnished by Beagles, is arranged in the order of securing the varieties, not alphabetically, and the first forty-four sorts are from the well-authenticated collection at Chiswick, England:

De l'Archipel.
Bontard.
Grosse Marseilles.
Peau dure.
Negronne.
Bourjassotte noire.
Poulette.
Ceil de Perdrix.
Du Roi.
Grosse Violette de Bordeaux.
Datte.
Monstrueuse.
Bourjassote grise.
A' Bois Jaspee.
Royal Vineyard.
De Grasse.
Euscaire Preto.
Trois recoltes.
Monaco bianco.
Bondance Precoce.
Trifer.
Green Ischia.
Hirta du Japon.
St. Johns.
Vebra.
Datte Quotidienne.
Arbal.
De Jerusalem.
Nebian.
Vigasotte Bianco.
Grise Savantine bifere.
Quarteria.
Douro Vebra.
Reculver.
Gourand Rouge.
D'Agen.
Lampa.
Large Black Douro.
Adam.
De Constantine.
Biberaeo.
Grosse Verte.
Violette Sepor.

The California Experiment Station, under Hilgard, found that several varieties which are no longer in ordinary cultivation were important. Chief among these was a French fig of compact growth, Hirta du Japon, a medium-sized, turbinate, dark purple fig of high quality. It is excellent for house culture and for small gardens.

Smyrna figs.

The story of the introduction of the fig-wasp, the indispensable Blastophaga, to California fig orchards is one of the amusing, pathetic and fascinating romances of outdoor life. Smyrna figs were planted early, and they did not bear; the trouble was indistinctly charged to "the climate;" growers laughed at the absurd "book notion" that the Asia Minor Greeks depended on "some sort of an insect" to secure abundant crops of fruit. The late John Bleasdale, who had been in Portugal, told many persons about fig-caprification early in the 1870's. Some of the nurserymen took it up with energy and managed to secure cuttings of Smyrna figs and of Capri figs, but no insects. The San Francisco "Bulletin," between 1880 and 1882, secured and distributed over California about 14,000 cuttings. The fig-growers in Asia Minor became anxious to prevent importation of the insects to California or of the Capri fig cuttings, and the difficulties grew worse. Eisen and Rixford cross-fertilized figs by hand as soon as the wild fig trees blossomed. This was done on the James Shinn farm at Niles and at the California Nursery (managed by John Rock) in the same neighborhood. Then the Roedings of Fresno became interested, through Eisen, and planted a Smyrna fig orchard, but had no Blastophaga. Meanwhile the Department of Agriculture took hold. Walter Swingle was detailed and in 1899 secured the Algerian Blastophaga for the Californians. James Shinn, of Niles, had also obtained the Blastophaga in 1891, but his location was not suitable so that it perished and the work was done over again by both Swingle in 1899 and George Roeding, of Fresno, in 1896, working separately at different points of the problem. But all this time, the fig-wasp had accidentally become established near Modesto, about 1869, on the Gates farm. The wild fig tree there was, possibly, imported by West, of Stockton, in the form of cuttings carrying some of the "mamme" or winter generation of fruits containing the Blastophagas.

The literature of this whole subject is fascinating. It may be studied in the reports of the Department of Agriculture and in the following papers: "Some Points in the History of Caprification and in the Life History of the Fig," Walter T. Swingle, before the Thirty-fourth Fruit-Growers' Convention of California (1908); also his paper on the Maslin seedling fig orchard in the report of the thirty-fifth convention; also papers of his in the thirty-sixth and thirty-eighth reports; an essay by G. P. Rixford, read before the Forty-first Convention of California Fruit-Growers, in Santa Barbara, in 1912. His botanical and entomological paper, read in 1911 before the Pacific Association of Scientific Societies, on the "Fructification of the Fig by Blastophaga" traces the whole subject down from the days of Linnæus. A practical paper on the subject is to be found in George C. Roeding's "California Horticulture," a pamphlet issued in 1909.

Caprification.

The work of study and experimentation has gone forward steadily since the first importation of the Blastophaga; it is likely that more has been done in this line in California in the past twenty years than in all the rest of the world put together. The practical methods of keeping the fig insect prosperously established so that every fruit can be fertilized are now well founded, and as the profits of the industry are generally recognized, large plantings can be expected. There are some obscure problems still undetermined relating to the different crops of figs and the fructification of some of the non-Smyrna types. But in California the industry as a whole finds possibly the most favorable soil and climate known to exist anywhere. It seems probable, therefore, that fig-growing will soon rank in importance with the growing of citrous fruits. The cultivated varieties of Smyrnas are doubtless capable of much improvement as regards size, crop and season.

Only thirty Capri figs are needed to caprify a large fig tree, so abundant are the insects and the pollen in good seasons, and one tree of the wild fig is sufficient for one hundred Smyrna trees. The male of the fig-wasp is without wings, but the female has wings and saw-like mandibles; she cuts her way through scales which interlock over the apex of the half-grown Smyrna fig. She loses her wings in entering, dies in the fig and is absorbed by the vegetable cells. If she lays her eggs they also perish and the continuance of the species depends upon those individuals that remain upon the wild fig trees.

Propagation.

The fig grows readily from cuttings. Use well-ripened wood of the previous season's growth, cut at the joint, and give them the same treatment required for grape cuttings. They will even grow from single-eye cuttings. Bottom heat is not necessary in California where the cuttings are set in nursery in December or January and are ready for the orchard in a year. In the eastern states, winter-made cuttings can be started with bottom heat, or, in April, in the open air.

Budding is best done by the annular or ring method, so useful for the chestnut and walnut. The fig can be cleft-grafted in February in California, but extreme care must be taken to exclude the air. Seedlings are easily grown from the fertile seeds of the imported Smyrna figs, and from the few fertile seeds occasionally appearing in common varieties. Maslin, of Placer County, began to raise seedlings from imported dried figs in 1885 and these are now bearing.

Forcing.

The fig requires more heat under glass than does the grape. The temperatures preferred are, at first, 50° F. at night and, 65° for the day; later increase to 60° or 65° at night and 75° or more in the day. Figs must have much air and moisture till the crop is set. The best varieties for forcing are Early Violet, the White and Brown Ischias, White Marseilles, Hirta du Japon and Negro Largo. A soil of turfy loam with plenty of top-dressing is suitable for pots and tubs. Brown Turkey, Marseilles and Brunswick are the standard varieties for walls.

Cultural methods in California.

The fig tree in California requires much space, hence it is used as an avenue tree or if in orchard form other trees are set between, to be afterward removed. In good soil, fig trees, like walnuts, should finally stand not less than 40 feet apart, and 50 feet is considered to be better.

Little pruning is required for the fig. Trees grown for table figs are headed low, about 18 inches from the ground, to facilitate picking. Trees grown for drying figs are headed higher so that they can better be kept smooth and clean, as the figs are usually allowed to ripen and fall. Cultivation is necessary until the trees completely shade the ground.

Figs begin to bear early in California, often the second or third year. Some trees prove barren or very poor bearers and must be replaced by others. The tree appears to be as long-lived as the olive, has very few insect enemies, and is not subject to disease. It is a good ornamental tree.

The fruit in some districts, in some seasons, ferments on the trees ("fig-sour"). This sometimes seems to come from over-irrigation, sometimes from lack of vitality, and most often occurs in very tender and juicy varieties.

The very dangerous fig moth (*Ephestra cautella*) is now widely distributed in America, although not yet in California. During the last few years, many cargoes of imported figs have been seized in New York and destroyed on account of this insect, which fills the fruit with eggs and ultimately with its larvæ (Bulletin No. 104, 1911, Bureau of Entomology). Asiatic dried figs are not only subject to this pest but contain less sugar (1½ per cent less) and less proteids (1⅓ per cent) than do the California dried figs.

Fig-drying.—The fig crop is handled with much care and cleanliness in California, and labor-saving methods are used in all cases. The figs must remain on the trees till fully ripe; then they shrivel and drop off, are picked up, dipped in boiling brine (three ounces salt to one gallon water), placed on trays exposed to the sun and turned once. The later drying is done in the shade. The figs are next placed in the "sweat boxes" and "mixed" so as to equalize the moisture. They are then washed clean in a weak brine, drained off and taken to the packing-room. Exceeding care, cleanliness and much experience are required to produce high-grade results.

Fig avenues.—There is a growing interest felt in the fig as an avenue tree in California, since it is deciduous and so does not shade the road in winter, and since it thrives without culture or pruning where the moisture is sufficient and the soil deep.

Culture in other places.

While California probably offers the best climate on the continent for commercial fig-growing, the industry has a future over much of Arizona, New Mexico, Texas, the extreme South, Hawaii, Australia, large portions of South Africa, Mexico and the west coast of South America.

Fig-culture in the northern and middle parts of the United States is essentially different, of course, from the outdoor and orchard methods. The tree can be grown as a bush and protected each winter by covering the branches with several inches of soil. In the southern middle states, fig bushes are grown by covering in winter with matting and straw. One crop, or at most two, is all that can be expected. See the discussions on pages 1234 and 1235.

The crop.

Statistics are not well kept at present in the fig industry, but the annual California crop exceeds 4,000 tons (dried figs) while the local consumption of fresh figs is large and increasing. The fig pastes, conserves, and the like, and the use of figs in wafers and other forms is also general. As Smyrna exports about 30,000 tons in good years, there is evidently room for the California industry. The dried Smyrnas of California are equal to the best of Asia Minor and contain 64 per cent of sugar (Roeding's Calimyrna variety, the Erbeyli variety of its native country). Besides this variety, persons at Fresno are planting on a large scale the Kassaba, the Checker Injir of Scios, the Bardajic and what is called in California the purple Bulletin Smyrna.

Related species of Ficus.

The famous and useful "Sycamore fig" of the Orient (*Ficus Sycomorus*) produces fruit in racemes on the older branches. It is too tender for outdoor culture in America. (See page 1234.) The beautiful peepul tree of India is the sacred fig (*Ficus religiosa*) of the Brahmans and Buddhists, and it is now found in many private collections in southern California. *Ficus elastica*, the India rubber tree, is often seen in the warmer parts of California. In 1914 a tree of *F. elastica* fruited heavily at Niles and the children seemed to like the figs. The true banyan fig has not yet been successfully grown in the state, but ought to be tested. In the American tropics many interesting kinds of Ficus may be expected.

FILBERT. One of the group of nuts produced by species of Corylus. The nuts of Corylus are variously grouped or classified; those are usually known as filberts that are provided with a tubular husk much longer than the nut itself; as cobs, if the husk is little or not at all longer than the nut; and as hazels if the husk is much shorter than the nut. The filbert nuts are usually oblong in shape; the cobs roundish and angular; and the hazels rather small, roundish and thick-shelled. These are derived from different species and hybrids of Corylus (which see) of the Old World; and these vernacular names do not seem to be very definitely or accurately used. The name filbert is of disputed origin; the idea that it comes from "full-beard," in allusion to the long husk, is undoubtedly erroneous.

Filberts are grown in many parts of Europe, and they are exported to America in large quantities. Many attempts have been made to grow them in this country but without success owing, apparently, to lack of hardiness, to fungous disease, and to the want of varieties bred for American conditions. Probably some of the failure is due to lack of discrimination in soils and to unskilled methods of growing. See *Hazel-nut.*

L. H. B.

FILIPÉNDULA (Latin *filum*, thread, *pendulus*, hanging; alluding to the numerous small tubers hanging together by thread-like roots). Syn., *Ulmària. Rosàceæ* MEADOW-SWEET. Hardy herbs grown for their showy panicles of white, pink or purple flowers.

Perennials with fibrous or tuberous rootstock: lvs. stipulate, interruptedly odd-pinnate, the terminal lft. often much larger and palmately lobed: fls. in cymose corymbs; calyx-lobes and petals usually 5; stamens 20–40, with the filaments narrowed toward the base; carpels distinct, 5–15, 1-seeded, indehiscent.—Nine species in N. Asia and Himalayas, N. Amer. and Eu. Filipendula has usually been united with Spiræa, but is very distinct in its herbaceous habit, pinnate stipulate lvs. and indehiscent 1-seeded achenes.

The meadow-sweets are hardy plants with rather large pinnate or palmately lobed leaves and white, pink or purple flowers in showy terminal corymbs, borne on erect leafy stems rising 1 to 10 feet from a rosette of radical leaves. They bloom in early summer or midsummer and are very handsome border plants. Most of them delight in a rather moist and rich soil and are especially decorative if planted on the borders of ponds and brooklets, but *F. hexapetala* prefers drier situations and likes full sun, while most of the others also thrive well in partly shaded positions. *F. purpurea* should be mulched during the winter in the North. Propagated by seeds sown in fall in pans or boxes and kept in the cool greenhouse, or sown in spring; also by division of older plants.

A. *Lfts. numerous, almost alike, small, pinnately lobed.*

hexapétala, Gilib. (*F. Filipéndula,* Voss. *Ulmària Filipéndula,* Hill. *Spiræa Filipéndula,* Linn.). MEADOW-SWEET. DROPWORT. Fig. 1507. One to 3 ft. high, with tuberous rootstock, glabrous: radical lvs. 6–20 in. long; lfts. sessile, oblong, pinnately lobed and serrate, 1 in. long: fls. in a loose corymb, white, about ¾in. across, with usually 6 petals: achenes about 12, pubescent, semi-cordate. June, July. Eu., W. Asia and Siberia. Var. **flòre-plèno** has double fls., and is common.

1507. Filipendula hexapetala (plant about 2 feet high). Commonly known as Spiræa Filipendula. One of the plants called meadow-sweet.

AA. *Lfts. few, the terminal one much larger and palmately 3–9-lobed.*

B. *Lateral lfts. 3–5-lobed.*

rùbra, Rob. (*Spiræa lobàta,* Gronov. *Spiræa palmàta,* Linn. *F. lobàta,* Maxim. *Ulmària rùbra,* Hill). QUEEN OF THE PRAIRIE. Height 2–8 ft., glabrous: terminal lft. large, 7–9-parted, with oblong, acuminate incisely serrate lobes; lateral lfts. smaller, 3–5-lobed, on the upper lvs. missing, green on both sides, only pubescent on the veins beneath: fls. pink, in a rather large paniculate cyme: achenes 6–10, glabrous. June, July. Pa. to Ga., west to Mich. and Ky. Mn. 2:145. B.B. (ed. 2) 2:249.—Beautiful. Var. **venústa,** Voss. Fls. deep pink or carmine. Var. **álbicans,** Hort. Fls. light pink, or almost white. R.B. 3:169.

palmàta, Maxim. (*Spiræa palmàta,* Pall. *Ulmària palmàta,* Focke. *Spiræa digitàta,* Willd.). Height 2–3 ft.: lvs. whitish tomentose beneath or glabrous; terminal lfts. 7–9-parted; stipules large, semi-cordate: fls. pale pink at first, changing to white: achenes 5–8. July. Siberia, Kamchatka and Saghalin.—This species is but rarely cult.; the plant common under the name *Spiræa palmata* belongs to *F. purpurea.*

BB. *Lateral lfts. none or few and ovate.*

C. *Achenes usually 5, ciliate: lateral lfts. none or few.*

camtschática, Maxim. (*Spiræa camtschática,* Pall. *Spiræa gigantèa,* Hort. *Ulmària camtschática,* Rehd.). Height 5–10 ft.: lvs. glabrous or villous beneath, often with rufous veins; terminal lft. very large, cordate, 3–5-lobed, with broadly ovate, doubly serrate lobes; lateral lfts. usually none; stipules large, semi-cordate: fls. white. July. Manchuria, Kamchatka.

purpùrea, Maxim. (*Spiræa palmàta,* Thunb. *Ulmària purpùrea,* Rehd.). Height 2–4 ft., glabrous: terminal lft. very large, cordate, 5–7-lobed, with oblong, acuminate, doubly serrate lobes; lateral lfts. none or few, oblong-ovate; stipules narrow: fls. carmine or deep pink, in large paniculate cymes with crimson peduncles and sts. June–Aug. Japan. B.M. 5726. I.H. 15:577. F.S. 18:1851. J.H. III. 51:201. F.W. 1869:33. Gn. W. 23: suppl. June 16. Gn. 17:36.—This is undoubtedly the finest species of this genus. It is also sometimes grown in pots and forced. Var. **álba,** Hort., has white fls. and var. **élegans,** Voss, white fls., with red stamens and usually several lateral lfts.; the latter is said to be a hybrid. R.B. 4:7. G.Z. 22:25.

CC. *Achenes about 10: lateral lfts. present, ovate.*

Ulmària, Maxim. (*Spiræa Ulmària,* Linn. *Ulmària pentapétala,* Gilib. *U. palústris,* Moench). QUEEN OF THE MEADOWS. Height 2–6 ft.: lvs. glabrous or puberulous above, whitish tomentose beneath; terminal lfts. 3–5-lobed, 2–4 in. long, lateral lfts. smaller, ovate, coarsely doubly serrate: fls. white, in rather dense paniculate cymes: achenes about 10, semi-cordate, almost glabrous, twisted. June–Aug. Eu., W. Asia to Mongolia; naturalized in some places in the eastern states. B.B. (ed. 2) 2:249. Var. **denudàta,** Maxim. (*F. denudàta,* Rydb.). Lvs. green beneath and nearly glabrous. Var. **aùreo-variegàta,** Voss, has the lvs. variegated with yellow. Var. **plèna,** Voss (var. *flòre-plèno,* Hort.). Fls. double.

F. angustifòlia, Maxim. (Spiræa angustifolia, Turcz. Ulmaria angustifolia, Rehd.). Similar to F. lobata: fls. white: lvs. glabrous or whitish tomentose beneath. Dahuria, Manchuria.—*F. vestìta,* Maxim. (Ulmaria vestita, Rehd. Spiræa vestita, Wall.). Similar to F. camtschatica, but only 1 ft. high and lvs. grayish tomentose beneath: fls. white. Himalayas. B.R. 27:4 (as S. kamschatica var. himalensis).

ALFRED REHDER.

FINGER-GRASS. Species of *Chloris* and *Panicum.*

FIORIN: *Agrostis stolonifera* and *A. alba.*

FIR. Strictly, species of the genus Abies, but popularly it includes many trees known to nurserymen and others as Picea, and by some it is applied to Pinus, Larix, and others.

FIRE-CRACKER, FLORAL: *Brevoortia.*

FIRE-ON-THE-MOUNTAIN: *Euphorbia heterophylla.*

FIRE-PINK: *Silene virginica.*

FIRE-PLANT: *Euphorbia heterophylla.*

FIRE-WEED: *Epilobium angustifolium* and *Erechtites hieracifolia.*

FISH-GRASS: *Cabomba.*

FITTÒNIA (Elizabeth and Sarah Mary Fitton, authors of "Conversations on Botany," and friends of Robert Brown). *Acanthàceæ.* Low-growing herbaceous perennials, valued for the brilliant variegation made by red or white venation of their large heart-shaped leaves.

Leaves prominent or rather large, cordate, beautifully veined: fls. borne singly in the axils of the overlapping bracts, which form a peduncled, terminal spike; calyx-segms. linear-bristly; corolla-tube slender; lip long, narrow, shortly lobed at the apex; stamens 2, affixed near the throat; style filiform, truncate at apex: fr. an ovate-acute 4-seeded caps., some of the seeds likely to be aborted.—Species 3, in Peru. Fittonias may be grown with philodendron, *Cissus discolor*, *Episcia cupreata,* nephthytis and selaginellas. There is often a bare, unsightly space under the benches that can be transformed into a tangle of tropical creepers by the use of such plants. A board may be placed slanting toward the walks and covered with rotten stumps, chunks of peat, and moss for the plants to run in. The open borders near the walks have hardly sufficient drainage. They may also be pegged down in mossy coverings for tubs of palms, as they can stand much watering.

Fittonias are most useful and ornamental plants for growing in a deeply shaded place in the tropical greenhouse. The beautiful markings of their foliage always attract attention; and being of easy culture, they can be used effectively for places in the foliage house in which no other plant would thrive. The best time to root fittonias is early spring, as after a year's growth they are likely to have a rather straggling appearance, and need a general overhauling. Remove the points of the shoots, with two leaves attached, and one joint to insert in the sand. These make the best cuttings, but any part of the stem will root and grow provided there is a joint on it. After cuttings are rooted, which will be in two or three weeks in a temperature of 65°, pot them singly in 2-inch pots, in equal parts of loam leaf-mold, and sand.—When they are well rooted in these small pots, choose the size of pan they are intended to grow in, and fill it with the same proportion of loam, leaf-mold and sand, as advised for the first potting. This time, however, the loam is better to be more of fibrous and in a rather lumpy state, and the leaf-mold should not be too well rotted, but rather flaky in texture. In filling the pan with the compost, raise it in the center above the rim. This gives the plant a mound appearance, which adds to its beauty. The small plants should be planted in the large pan about 2 inches apart; water them gently with a fine rose, so as not to disturb the earth in the receptacle. As stated above, these plants require, at all times, to be grown in a shady position, and except in the dead of winter should never be in a temperature of less than 60° by night. In severe zero weather, it will not harm them to drop as low as 55°.—Pyramid-shaped plants of some of the fittonias can be grown. Pot them along singly and tie them to a stake. When about four or five pairs of leaves are formed, pinch out the heart of the plant. This will encourage side breaks to start, which should be pinched after they have made three pairs of leaves. After the leading shoot has been pinched, two breaks will start away, and after two leaves have been well formed, one of the shoots should again have the heart taken out of it. The other must now be taken for the leader and allowed to make three or four more joints before it is stopped again by removing the heart. In this way the desired height will be attained, and at the same time plenty of side breaks will be encouraged to start. The side shoots must be carefully watched; pinch back all the strong shoots, so that a plant of symmetry may be formed. When these plants are well rooted in the pans, or have attained the desired size in pyramid form, water them occasionally with soft-coal soot, a handful to an ordinary watering-pot, which generally contains about two and a half gallons. Water twice in between with clean water. The soot tends to bring out the brilliancy of the markings, making the whole plant have a glossy appearance. Scale, and other insect pests are sometimes found on these plants, but if fumigated with hydrocyanic gas, as advised for other plants, will give very little trouble. (George F. Stewart.)

1508. Fittonia argyroneura. (×¼)

A. *Habit erect: height 1½ ft.*

gigantèa, Lind. (*Gymnostàchyum gigantèa,* Hort.). Sub-shrubby, branching, 1½ ft.: sts. reddish violet only between the joints, with 4 ranks of silky, white, erect hairs: lvs. opposite, elliptical, not notched at the base, with 2 ranks of hairs, tapering more than in the other species, dark, shining green; veins carmine-red: fls. pale, with a reddish brown band in the middle of the side and upper lobes, and a dark yellow spot in the middle of the lower lip. R.H. 1869, p. 186. I.H. 16:611.

AA. *Habit trailing or dwarf: height about 6 in.*

B. *Veins of lf. red.*

Verschafféltii, E. Coëm. (*Fittònia* and *Eránthemum rubronérvum* and *rubrovenòsum,* Hort. *Eránthemum rùbro-vènium,* Veitch. *Gymnostàchyum Verschaffèltii,* Lem.). Lvs. ovate, notched at the base, dull green, often yellowish, veined carmine. F.S. 15:1581. I.H. 10:372. Var. **Pèarcei,** Hort. (*F.* and *G. Pèarcei,* Hort.). Lvs. light, bright green; veins light, bright carmine; under surface somewhat glaucous. Var. **Dàveana,** Hort. (*F. Dàveana,* Hort.). "Foliage with light center, bordered very dark green." More robust than the type and with veins of stronger red.

BB. *Veins of lf. white.*

argyroneùra, E. Coëm. Fig. 1508. Dwarf: lvs. dark, shining green. F.S. 16:1664. Gn. 36, p. 527; 2, p. 319. G. 11:7.—The velvetiness of the upper surface of *F. Verschaffeltii* is due to large projecting epidermal cells with an apical nucleus. Instead of these characteristic cells, *F. argyroneura* has small cells and conical hairs, which are partitioned off and have tubercles at the base.

WILHELM MILLER.

FITZRÒYA (Capt. R. Fitzroy, of the British Navy; died 1855). *Pinàceæ.* Two evergreen trees or shrubs, one of the mountains of S. Chile (*F. patagònica,* Hook. f. B.M. 4616), and one of Tasmania (*F. Árcheri,* Benth.). Lvs. small, 3-verticillate or decussate-opposite, imbricated: catkins very small, globose. They are little known in this country, and may be expected to thrive only in the milder parts. The former species is a tree, has lvs. mostly verticillate, ovate-oblong, in 2–4 rows, anthers commonly 4-celled, 3 ovules, and seeds 2-winged; the latter is bushy, has opposite decussate keeled lvs., anthers 2-celled, ovules 2, seeds 3-winged. The Biltmore Nursery, N. C., lists *F. patagonica,* "a tree of variable dimensions, native of the Andes, from Chile to the Straits of Magellan. Lvs. dark green above, with 2 white lines beneath. . . . Its value in cult. in the U. S. has not yet been fully proved;" but it is said to possess sufficient hardiness to withstand the winters in the S. It is reported as being hardy in S. England. It is monœcious, the small cones consisting of about 9 scales; the lvs. on small trees are reported as varying much in the way in which they stand on the st., but they are 4-rowed and decurrent; pollen-sacs mostly 4.

L. H. B.

FIVE-FINGER: *Potentilla.*

FLACOÚRTIA (Etienne de Flacourt, 1607–1660, General Director of the French East India Company, Governor of Madagascar and author of a history of Madagascar). *Flacourtiàceæ.* One of the species, a shrub with edible fruits, is cultivated in the tropics and has been introduced in southern California and perhaps elsewhere.

Shrubs and small trees, often spine-bearing: lvs. short-stalked, toothed or crenate, simple, alternate: fls. small, diœcious, in small racemes or glomes or panicles (the fertile ones sometimes solitary); sepals

4–5, scale-like, ciliated, overlapping; petals none; stamens many; styles 2 to many; ovary 2–5-celled: fr. a berry, often edible, usually with 1 seed in each cell.—Fifteen to 20 species in Trop. Afr., Asia, and islands.

Ramóntchi, L'Her. GOVERNOR PLUM. BATOKO PLUM in the Zambesi region. Fig. 1509. An excessively variable shrub or small tree, as customarily defined, native in Trop. Afr. and Asia, and planted in the American tropics: glabrous or nearly so, spiny or spineless (spines axillary): lvs. oblong to elliptical and obovate, obtuse or pointed, variously crenate-dentate, short-petioled: sterile fls. in short racemes, the fertile few or solitary or in pairs, all small; styles 5–7, very short, radiate: fr. cherry-like, to 1 in. diam., roundish and pulpy, with 8–10 seeds, purple, red, or blackish, bearing on top the remains of the stigmas; edible, ripening in the farther West Indies early in the year but some specimens sometimes remaining till Sept. There are various forms, as var. *inermis* and var. *macrocarpa*. Hooker & Thomson in "Flora of British India" recognize 5 marked varieties, and include within the species *F. sapida* of Roxburgh. The species is reported as "common throughout India, wild or cult." and as having a distribution from Madagascar to the E. Archipelago. Duthie, in "Flora of the Upper Gangetic Plain," says that the var. *sapida* (with pubescent branchlets, elliptic or suborbicular lvs. which are glabrous or puberulous only on the veins beneath) produces fr. that is eaten raw or cooked, and twigs and lvs. that are used as fodder. "Ramontchi" is said to be the native name in Madagascar. L. H. B.

FLEABANE: *Erigeron.*

FLEMÍNGIA (John Fleming, Pres. Medical Board of Bengal; author of "A Catalogue of Indian Medicinal Plants and Drugs," 1810). *Leguminòsæ.* Of this genus, two shrubs are cultivated in southern California and southern Florida.

Herbs, sub-shrubs or shrubs of the Old World tropics, erect, prostrate or twining: lvs. mostly with 3 digitate lfts., rarely 1; stipules striate, often caducous: fls. papilionaceous, red or purple and mixed with yellow, in crowded racemes or panicles, or sometimes solitary; standard obovate or orbicular, auricled at base; wings obliquely obovate or oblong, often adhering to the incurved or nearly straight keel; stamens 9 and 1: pod short, oblique, swollen, 2-valved.—Species above 20, mostly of Trop. Asia, but occurring also in Trop. Afr. and to the Philippines. Allied to Dalbergia and Rhynchosia.

congésta, Roxbg. Shrub, 4–6 ft., erect: lfts. oblong or broadly lanceolate, the side ones 2-nerved, middle one 3-nerved: racemes axillary, dense, shorter than the lf.-stalks; fls. purple, with a silky-hairy calyx and a scarcely exserted corolla: pod ⅝in. long, 2-seeded.—A variable species of India.

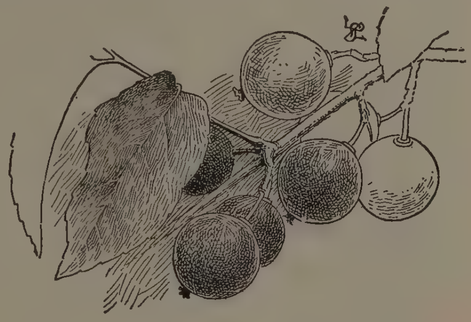
strobilífera, R. Br., has been intro. in S. Fla. It is an erect shrub, 8–10 ft., with slender velvety branches: lvs. simple, oblong, subacute, rounded at base, somewhat silky beneath: racemes zigzag, 3–6 in. long, with very large bracts that hide the fls.; calyx ¼in. long, hairy and with lanceolate teeth; corolla purple: pod less than ½in. long. India. L. H. B.

FLOATING HEART: *Limnanthemum.*

FLOÉRKEA DOÙGLASII: *Limnanthes.*

FLORA'S PAINT-BRUSH: A common name for *Emilia flammea.*

FLORICULTURE, or the growing of plants for ornamental purposes, particularly for flowers, is yearly assuming larger proportions in the United States. The industry consists in growing annual, biennial and perennial plants either under glass or outdoors, and in the disposal of the same in wholesale or retail markets. These products are sold as cut-flowers or potted plants to be used for indoor or outdoor home ornamentation, or for planting in public parks, about schools and other public buildings, or in cemeteries for ornamental purposes. (For home flower-gardens, see p. 1747.)



1509. Flacourtia Ramontchi. (×½)

Importance of the industry.

The floricultural statistics taken from the census of 1910 show a marked increase in the importance of this branch of agriculture within the previous decade. The acreage, as given for this census, was 18,248 as compared with 9,307 as given for the census of 1900. The total valuation, as given in this census, was $34,872,000, an increase of 85.9 per cent as compared with the report of the census for 1900. The figures were compiled in nine large geographical divisions of the United States. These were New England, Middle Atlantic, South Atlantic, East North Central, West North Central, East South Central, West South Central, Mountain, and Pacific.

From its beginning the industry has centered around such large cities as Boston, New York, Philadelphia, Baltimore and Washington. The business is now assuming considerable importance in Chicago, St. Louis and other large cities in the Middle States, the South and West. Statistics show that the largest floricultural output comes from the Middle Atlantic section. The states which compose this section are New York, New Jersey and Pennsylvania. The total valuation of products from this section is $11,810,076. The second section of importance is the East North Central, composed of Ohio, Indiana, Illinois, Michigan and Wisconsin, in which the figures given were $9,029,125. The third important section was New England, where the total valuation was $4,677,316. The smallest output comes from the Mountain section, composed of Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah and Nevada. Here the output was $753,914. The most rapid increase in the industry during the decade seems to have been in the Pacific section, composed of Washington, Oregon and California, where the valuation of flower products sprang from $726,968 in 1899 to $2,175,572 in 1909. New York leads other states in floricultural products, having an output of $5,110,221. The rank of other important states is Pennsylvania, Illinois, New Jersey, Massachusetts and Ohio.

Floriculture is intensive agriculture; consequently the acreage devoted to the industry is not so large as in other branches of agriculture. The amount of capital invested in glasshouses and their equipment is considerable. The return from the products, however, is immediate. Commercial growers and men making a business of greenhouse construction, estimate that it costs from 60 to 90 cents a square foot of ground covered to build and equip a modern range. The growers estimate that the products from such an area the first year should cover the cost of construction.

The flower-growing industry in the United States has not yet assumed the large proportions that it has in many European cities. The early colonists were an extremely practical people and paid little attention to the distinctly ornamental features about the home. As wealth increased, however, there came to be a more liberal use of flowers and plants; hence a larger demand for them in the industrial world.

Floricultural statistics for the Dominion of Canada are less complete than for the United States. The following are figures furnished through the courtesy of W. T. Macoun, Dominion Horticulturist:

Capital invested, approximately	$1,500,000
Square feet of glass	6,000,000
Annual output	$1,000,000
Area covered	120 acres

History of the industry.

The early history of the floricultural industry is obscure. It was merged to such an extent with other branches of horticulture and other industries that it could hardly be called a distinct industry. Previous to 1825 there is record of but few commercial flower-growing establishments. From 1830 to 1840, rapid progress was made in all branches of the work. The demand for glasshouse products increased to a considerable degree. Better houses were built, better systems of heating were devised, and consequently better products were put on the market.

Even the glasshouses of this period were extremely crude affairs. The framework was of large dimensions, the glass small in size, heavy and thick. The roofs were largely portable, being made of sash. About 1855 the first house having permanent sash-bars was built by Frederic A. Lord in Buffalo. The wooden superstructure of this house was heavy and the interior light conditions correspondingly poor, but it was a vast improvement over sash-houses. This type of construction was met with favor by glasshouse men, and many houses of a similar type soon were built. Glass of larger size was used, and this was embedded in putty instead of being placed on the outside as in sash-houses.

Previous to 1870 the principal business of the florist was the growing of potted plants. The flowers from these were often sold as cut-flowers, but the business centered about growing potted plants for outdoor bedding and other ornamental purposes. The cut-flowers of that early period were comparatively of a small-flowered, short-stemmed sort—heliotrope, camellia, tuberose, bouvardia and those of a like nature. Although the carnation was introduced as a florist crop about 1852, it was of little commercial importance previous to this date. About 1865, Dailledouze & Zeller of Flatbush, Long Island, began to breed the carnation, and between 1866 and 1872 several new varieties were introduced by this firm. Garden roses had been popular for many years, but few attempts were made to grow them under glass previous to 1870. They then came rapidly into public favor.

From 1870 to 1880 the demand for both potted plants and cut-flowers increased rapidly. More attention was paid to city and home ornamentation, and consequently more park and private conservatories were built. Each year witnessed improvements in construction, and consequently better grades of florists' products. In the last twenty years the advances which have been made in cultural conditions and the improvements in florists' crops have completely revolutionized the industry.

Improvements in glasshouse structures, and their heating.

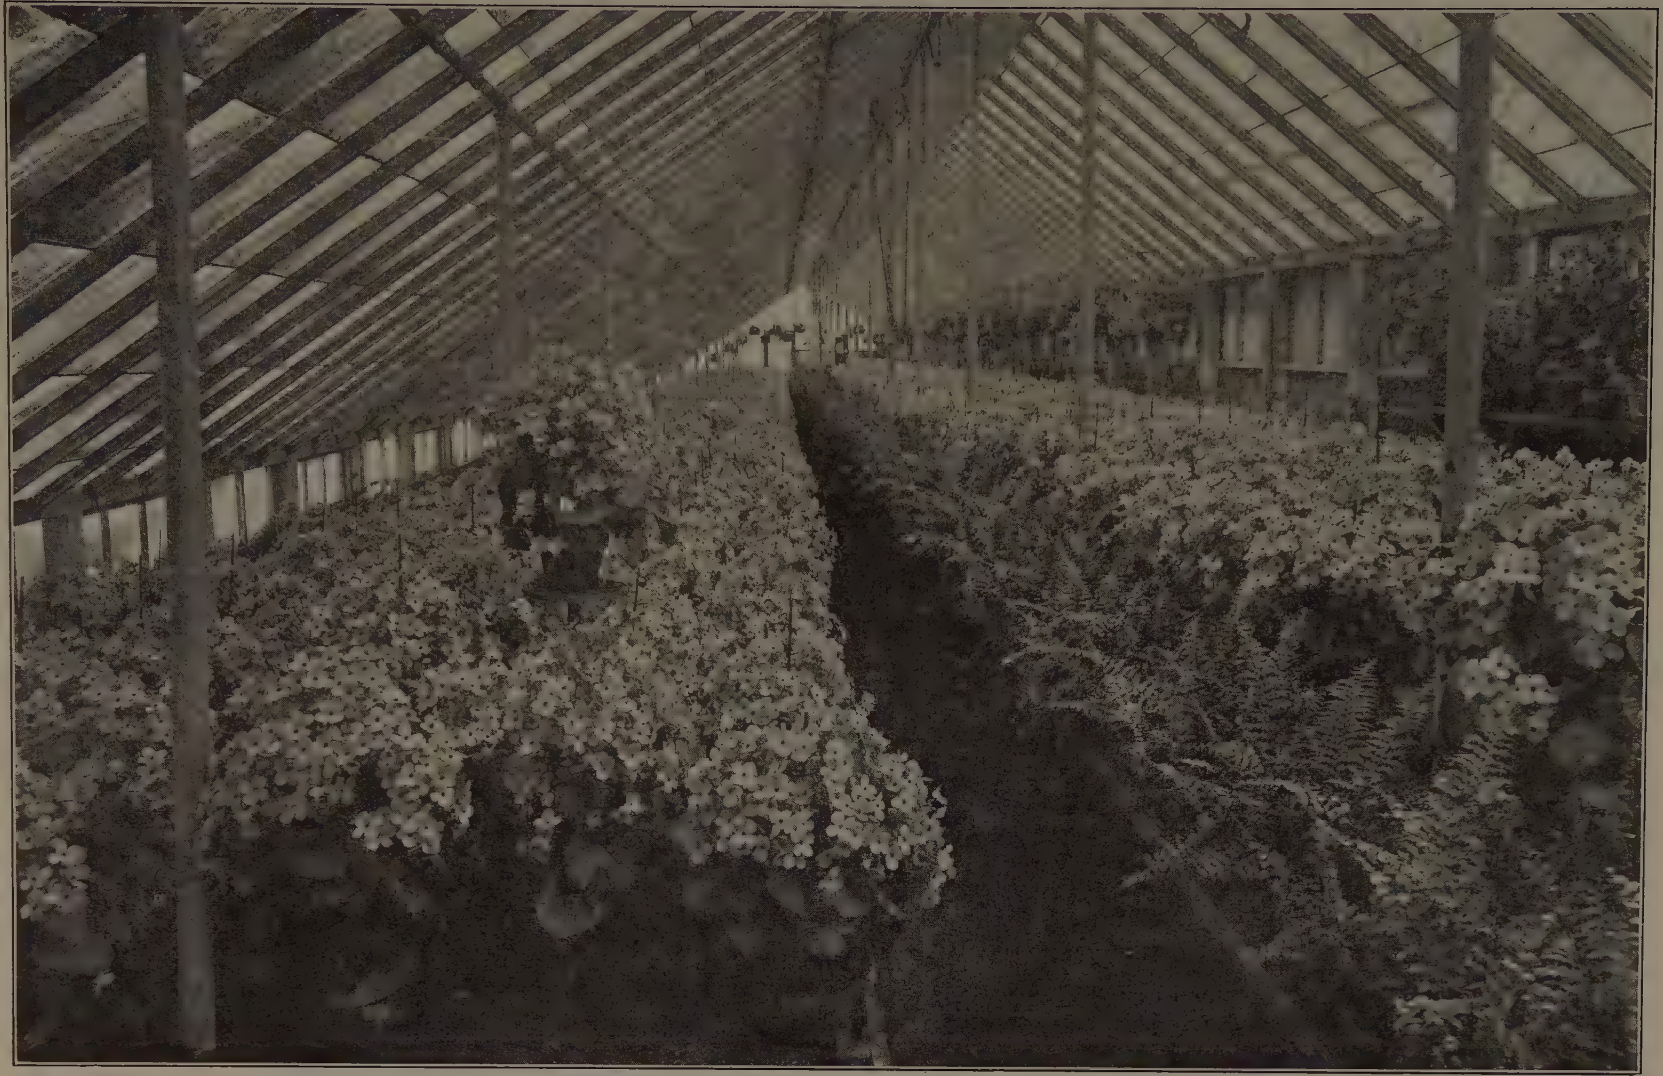
The tendency among flower-growers now is to build large houses in preference to smaller ones. It has been proved that the cost of construction is cheaper and that these may be more easily heated, that plant-growth is healthier because of a more uniform temperature, that they are easier to construct and can be cared for with greater economy of labor. Glass of larger size is now used, and more attention is given details of construction to increase the light factors in the house. There have been many changes in methods of heating glasshouses during their history. From the crude methods of flues, various devices for heating with hot water and steam have been devised. Both of these methods have their advantages. In the earlier methods of hot-water heating, the pipes were large and the system was an expensive one to install. Steam, therefore, came into popular favor, especially in large commercial establishments. It is still generally used. In some sections of the country and in the growing of some species of plants, hot water is still used; but here better systems for forcing the circulation of water have been installed so it is possible to use pipes of smaller dimensions.

Improvements in flower crops.

The work of the plant-breeders began to produce results in the the early nineties of last century. Many new varieties of chrysanthemums and carnations were put on the market. The violet then became an important florist crop. The early part of the twentieth century, however, witnessed a deluge of new varieties in practically all species. Breeding and improved cultural methods brought the qualities of the products far above anything produced in the previous century. Large-flowered carnations on long, stiff stems, violets of much larger sizes, and improved strains of chrysanthemums, roses and other species gave a remarkable impetus to the industry.

Previous to the beginning of the twentieth century, the American florist had interested himself in the culture of a wide variety of plants. In many cases the larger part of the products were sold at the range. The business, however, assumed such proportions that many up-to-date florists found that they could not profitably raise and dispose of their products at retail; consequently the retail flower-stores became more and more important factors in the disposal of the products. Wholesale commission houses and wholesale flower-markets were established in the larger cities so that the grower could devote nearly his entire time to the production of his crop. Many of the more progressive florists came to feel that they could not afford to grow a wide variety of plant species, but that it paid them better to grow one or two crops and to devote their whole attention to growing these in the finest manner possible so that they could produce flowers which were first quality in every respect; hence men came to be known as carnation, rose, violet, chrysanthemum, fern, palm and other specialists. This led to a wonderful improvement in the quality of flowers produced, and there was no call in the market for the inferior grades.

The buying public has had its influence in producing a better quality of florists' products. It has demanded not only better quality but something out of the ordinary. People tired of roses, carnations, violets and bulbous stock continually. The early part of the twentieth century witnessed a remarkable interest in orchids. The commercial man had to meet this demand. Twelve years ago an orchid could hardly be found outside of private conservatories. They were considered impossible to grow with financial success. Today nearly every



XLIII. Floriculture.—A house of begonias, with a row of ferns.

up-to-date retail grower has his section of orchids, and nearly every large floricultural center has its orchid specialist. For many years it was considered impossible to get satisfactory results from sweet peas under glass. The introduction of new strains and careful study of cultural conditions made the culture of this crop possible. The forcing of hardy herbaceous perennials like antirrhinums, delphiniums, and the like, and the forcing of hardy shrubs and other rare, hardy stock has furnished the flower-grower with a wonderful range of the more unusual plants.

Many large American flower-producers are now managing their business on a departmental scale. There are retail and wholesale departments; palm, carnation, orchid, rose, chrysanthemum and bedding departments, each in charge of a specialist in growing that particular crop.

The flower exhibitions held from time to time in the larger cities have had a beneficial effect on the uplift of the business. These exhibitions have been viewed by thousands of retail buyers. The choicest products of the flower-grower's skill have been exhibited, and the public has become dissatisfied with the inferior grade of commercial flowers offered for sale in the average flower-shops. They have demanded better products, and it has been the work of the flower-grower to produce these qualities.

Literature.

Within the last ten years there has been a remarkable increase in literature on flower-growing. Such papers as "The Florists' Exchange," "The American Florist," "Florists' Review," "Horticulture," "Gardening," "Gardener's Chronicle of America," have kept the grower closely in touch with the work in the gardening world. Many publications for the amateur, like "The Garden Magazine," "Country Life in America," "House & Garden," "Suburban Life" have assisted in giving the American people much valuable information regarding flower-growing about the home.

A long list of books might now be given, dealing with commercial and home flower-growing. Among these, valuable for the commercial man, are: "The American Carnation," C. W. Ward; "Commercial Rose-Culture," Eber Holmes; "Chrysanthemums for the Million," Charles H. Totty; "Violet-Culture," B. T. Galloway; "Orchid Culture," William Watson; "Florist's Manual," William Scott; "Plant-Culture," G. W. Oliver. Excellent books for the amateur are: "The Rose," H. B. Ellwanger; "Window-Gardening," H. B. Dorner; "The Garden Month by Month," Mrs. M. C. Sedgwick; "Making a Bulb Garden," Grace Tabor; "Roses and How to Grow Them," Doubleday, Page & Co.; "House Plants and How to Grow Them," Parker T. Barnes.

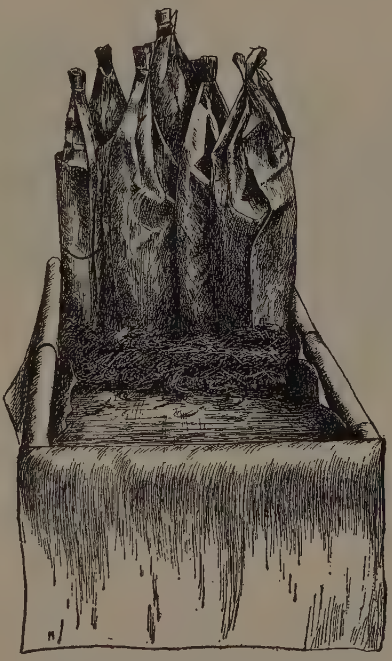
FLORISTS' PLANTS. A half-century ago the florist plant trade, although perhaps relatively of greater importance than at present, was not a prominent feature of the holiday trade. At Christmas there was some acceleration in the business, but this was overshadowed by the trade in cut-flowers. Easter was not a time of great plant sales. Church decorations in Protestant churches were not common. The sales of plants were more evenly distributed throughout the year, and the variety of plants sold was greater because the grower and consumer came in contact with each other, thus enabling the grower to dispose of plants which would not withstand the handling experienced by the plants of the present day. With the changing conditions in the family life of city residents, plants are no longer largely desired for window-gardens, but for temporary decoration of the living-rooms. The old type of plant-grower with his botanical collection has passed away, and in his place is the large commercial grower of a few staple plants which are grown in perfect condition. These growers produce a large quantity of plants for Christmas and then begin operations for Easter, as both of these dates now are times for the sending of gifts.

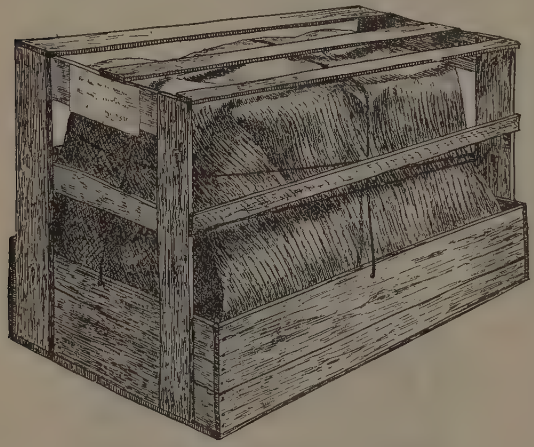
The trade in florist plants in the U. S., including bedding plants, is not less than $10,000,000, and it is encouraging that it is annually increasing without any diminution in the volume of the cut-flower business. Every up-to-date florist makes Christmas and Easter displays, and often special exhibits of chrysanthemums, and so on, are made when in season. The most successful of these displays are made in houses arranged for the purpose, for when made in an ordinary greenhouse with high benches, the taller plants are above the level of the eye and the effect is sacrificed. The best houses for displays are those of the conservatory type such as are seen in connection with some of the best flower stores. An ordinary greenhouse is often adapted for the purpose by constructing low benches, 18 to 20 inches high, for displaying bulbous plants and omitting them entirely for tall plants. The object sought in all cases is to have the plants placed so that the buyer looks down upon them. The show house is not very large for the reason that it is not always advisable to have too many plants of a kind in sight and also because at Easter the occurrence of warm, bright, unseasonable weather prevents keeping the plants in good condition. It is generally recognized that the display must be maintained in good condition by removing all unsightly plants and faded flowers. The stock should be replenished and rearranged every day.



1510. Pot-plants being packed for shipment.

The good salesman is one who has a knowledge of the care of plants, as well as their good points, their appropriateness for special occasions, and so on. Judicious advice on these points has much to do in winning and retaining customers. When a sale is made, the plants are carefully tagged with the correct address and the time it is to be delivered. If the plant is intended as a present, the sender's card is usually placed in a waterproof envelope which is fastened to the delivery tag. Deliveries of Christmas and Easter plants particularly should be promptly made, for nothing creates more dissatisfaction than late delivery. This requires skill in systematically arranging the plants according to the delivery routes, thus avoiding traversing the same territory a second time. It is axiomatic that the plant should be at its best on the day or at the function for which it is to be used. The weather has much to do with the condition of plants upon delivery. At Christmas, stock may be sent out twenty-four hours in advance, while at Easter stock delivered thus far in advance may not be satisfactory on Sunday.

All plants in pots, with the possible exception of the woody kinds, are staked and tied before handling. Plants are neatly wrapped with several thicknesses of paper to insure safe delivery. Plants with flowers which are easily bruised are usually wrapped with a sheet of cotton batting or waxed paper and then six to eight thicknesses of newspaper with clean plain paper outside. When plants must be shipped in cold weather, they must be wrapped as indicated and then set in strong wooden boxes. These boxes are approximately 4 feet long, 2 feet wide, and 8 inches deep. The corners are strengthened by the use of extra cleats. The box is first lined with corrugated paper, and then several thicknesses of newspaper which are left hanging over the edges of the box all around. Slightly dampened excelsior is used around the pots to prevent breakage and to make the package secure. The paper is then brought up over the plants and fastened (Fig. 1510). Over the top a frame is built of ½ x 4-inch cleating lumber which prevents damage to the plants (Fig. 1511).



1511. The completed crate for shipment.

The number of plants that can be had in perfection at Christmas is limited and does not change from year to year. Among the leading flowering plants are poinsettias in pots and pans, azaleas, cyclamen and Lorraine begonias. The more expensive plants are ericas (*E. melanthera*) and camellias.

The berried plants commonly grown are the Jerusalem cherry (*Solanum Capsicastrum*), Christmas pepper (*S. Pseudo-Capsicum*), aucubas, ardisias, holly and Otaheite oranges.

The foliage plants include araucarias, boxwood, crotons, nephrolepis, *Pandanus Veitchii*, *Ficus pandurata* and *F. elastica*, Dracæna (*D. terminalis*, *D. fragrans*, *D. Mandæana*, *D. Godseffiana*, *D.* Lord Wolseley) and Adiantum.

Easter is a great plant day and there is a great variety of suitable plants. The leading flowering plant is, of course, *Lilium longiflorum*.

It would be difficult to determine the relative market value of the different plants, but among the bulbs tulips, hyacinths, narcissi and lilies-of-the-valley are staples. These are sold in pots or pans, singly or in plant combinations. A very large amount of bulbous material is sold at Easter. Cinerarias, *Primula obconica* and *P. sinensis* are a smaller factor than formerly on the large city markets, but still remain an important item in the smaller cities. Marguerites and spirea (*Astilbe japonica*), when well grown, find a good sale in New York. A number of violets and pansies planted in low dishes, and small blooming geraniums, from 3-inch pots, planted in 6- to 12-inch bulb pans, are salable plants in many localities. Among the shrubs the azaleas are most important, although in some cities they show a decline in popularity. Following these are genistas, which have been for many years a popular Easter plant. *Hydrangea rosea* and *H. Otaksa* were long standard varieties, but now will probably give way to the new French varieties. In some cities hydrangeas are less used for Easter than for Memorial Day. Lilacs, Charles X, Marie Legraye and Madame Lemoine are among the best. The lilac has the disadvantage of a great display of wood and leaves before the terminal flowers charm the eye. It therefore requires accessories to relieve this effect, and the demand for this plant is limited. Rhododendrons are slowly gaining in popularity. Acacias and ericas are becoming more common each year. *Acacia longifolia* and *A. paradoxa* are now grown for market. *Erica Cavendishii* is used for individual plants, while *E. cupressina* is used in making up baskets of plants. *Bougainvillea Sanderiana*, like the rambler roses, may be made to assume definite forms which are especially beautiful when the bracts are well colored. Among the other shrubs more or less common are *Azalea mollis*, *Deutzia gracilis*, *Spiræa Van Houttei*, double almond, hawthorns, and *Wistaria multijuga*. In the last decade the rambler roses have taken a prominent place among Easter plants and each year a larger number are grown. The crimson rambler was first used, but is now superseded by the more beautiful Dorothy Perkins, Tausendschon, Lady Gay, Newport Fairy and Hiawatha. The rambler roses possess the advantage that they can be trained into pleasing forms. The polyantha roses are popular also, and among the varieties used are Madame Norbert Levavasseur (Baby Rambler), Mrs. Cutbush and Orleans. The latter are very satisfactory when sold either as individual plants with waterproof crepe paper pot-covers or in baskets with other plants. The hybrid perpetuals are still grown, but not in so large quantities as formerly. The varieties now grown are Frau Karl Druschki, Mrs. John Laing and Magna Charta.

Easter brings a demand for some of the larger sizes of foliage plants for decorations in churches, retail stores, and the like. The small-sized ferns, dracenas and palms are required in making up baskets of plants.

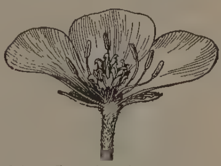
The florist of fifty years ago thought that a good blooming plant did not need any aids to make it attractive. This has changed, and the florists are seeking every means to make their plants more attractive. The most inexpensive method of doing this is to use pot-covers of waterproof crepe paper in color suited to the subjects. Porto Rican or raffia matting in color is used in a similar manner.

The trade of the present day disposes of a great many plants in baskets or boxes. Individual plant-baskets, with handles, to hold even as large as 6- to 8-inch pots are often used. Baskets, usually of the peach-basket shape, are also utilized for an endless variety of combinations of flowering and foliage plants (Fig. 1512). The baskets are supplied with a metal receptacle or lining so that the pots may be removed from the plants, giving them the appearance of having been grown together. Formerly these receptacles were filled by the retailers, but now many are prepared at the greenhouses according to order and sent to the stores where all that is needed is to add the basket and the ribbons. The latter plan relieves the store of much work in the busy season, but may not result in as artistic combinations as can be secured by a person trained in the work. The manufacturers of florist supplies are striving to meet the demand for something new in baskets and boxes. New material, weaves and shapes, are seen every year. There is also a great variety of coloring. There are green, gilt, white, red, ivory, bronze and copper shades as well as two-tone effects, as red and green, white and green, blue and white, pink and white, and yellow and white. The variety offered is such that baskets can be secured in sizes to suit either the high-class or popular trade. The small florist usually begins by using some of the willow, rattan or splint baskets which are filled with inexpensive plants. Cedar tubs, wood and terra-cotta boxes are also used. The demand for pleasing arrangements of flowering and foliage plants in boxes, jardinières, hampers, baskets, pans and dishes of fanciful design, light and airy, dainty and graceful, is increasing and is receiving the attention of the growers of holiday plants. It is generally recognized that the work offers as wide a scope for inventive genius and artistic discernment as any phase of the florist business. A. C. Beal.

1512. A made-up basket of living plants.

FLOWER is a popular or semi-technical term for the aggregate of structures having to do with sexual reproduction in the higher plants. The concept usually includes color, and a definite organization as outlined below; therefore, gymnosperms, ferns, and the lower plants are said not to have true flowers. As ordinarily understood, the flower is a showy structure useful for esthetic purposes, gratifying in color and often in odor, and in some way intimately connected with the production of seed; but analogous although inconspicuous structures are sometimes popularly recognized as "flowers." To the layman, many of our common herbs, shrubs and trees are said not to bear flowers at all, although the botanist recognizes that at least inconspicuous greenish flowers are borne by all of these plants unless they be ferns or gymnosperms.

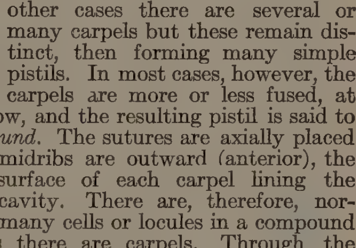
Botanically considered, the flower when complete consists of four sets of organs from the center outward: the gynœcium, andrœcium, corolla, and calyx, to which may possibly be added a fifth, the disk (Figs. 1513–1516).



1513. Longitudinal section of a buttercup flower.

The gynœcium Figs. 1517–1519).—In the center are one or more small flask-like or pouch-like organs (*pistils*) which are hollow and contain tiny bud-like growths (ovules). The pistils collectively are termed the *gynœcium* (female household). The hollow ovule-bearing part of the pistil is the *ovary*. At the summit of the ovary is a more or less sticky or roughened surface, the *stigma*, which may rest directly on the ovary (*sessile*) or may be raised aloft on a stalk (the *style*). From the ovules seeds are developed (see *Fertilization*).

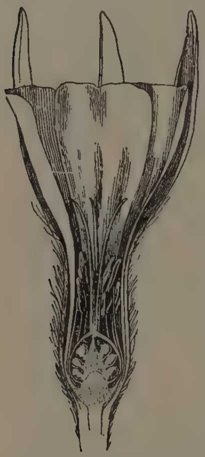
The fundamental or unit foliar organ of the gynœcium is termed a *carpel*. In the simplest case there is but one carpel, folded to form a pouch with the upper ventral leaf-surface within, and the margins forming a suture down one side. The structure thus formed is a *simple pistil*. The suture bears the ovules and is termed the *placenta*, and is normally ovuliferous throughout, but frequently only the uppermost or basal ovule of the row is present (*apical* and *suspended*, or *basal* and *erect*). In other cases there are several or many carpels but these remain distinct, then forming many simple pistils. In most cases, however, the carpels are more or less fused, at least below, and the resulting pistil is said to be *compound*. The sutures are axially placed and the midribs are outward (anterior), the ventral surface of each carpel lining the ovarian cavity. There are, therefore, normally as many cells or locules in a compound ovary as there are carpels. Through the partical opening-out of each carpel while the margins of adjacent carpels still remain united, the ovary may become one-celled though still compound, as in the violet. The placenta will in this case be *parietal* (on the walls). In certain families (Caryophyllaceæ, Primulaceæ) the compound ovaries are one-celled but have a *basal placenta*, or this basal placenta may project upward into the single chamber of the ovary as a central post on which the ovules are borne (*free-central placenta*) (Fig. 1515). To determine the number of carpels in a given pistil is often difficult. If there are several separate stigmas or styles, it is usually safe to infer that each represents a carpel. If the ovary is several-celled, each cell usually denotes a carpel and in one-celled ovaries the placentæ, if parietal, denote the number of carpels. In the case of a pistil with a one-celled ovary, basal placenta, one style and one stigma, only developmental or phylogenetic studies will show how many carpels are present.



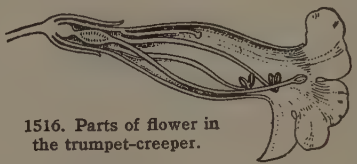
1514. Structure of flower.—The plum.

se. sepals; *p.* petals; *sta.* stamens; *o.* ovary; *s.* style; *st.* stigma. The pistil consists of the ovary, style, and stigma. It contains the seed part. The stamens are tipped with anthers, in which the pollen is borne. The ovary, *o*, ripens into the fruit.

Ovaries are sometimes raised on a stalk within the flower, as in the caper family (*gynophore*) and in Coptis (*thecophore*). The styles and stigmas are frequently much modified for pollination purposes, as in the orchids and in the pitcher plant (Sarracenia).



1515. Section of a flower of corn-cockle.
Showing torus, ovary, styles, stamens and floral envelopes.



1516. Parts of flower in the trumpet-creeper.

The andrœcium (Figs. 1520–1522).—Surrounding the pistils are found one or more whorls of organs called *stamens,* collectively termed the *andrœcium* (male household). A stamen normally consists of a slender stalk (*filament*) capped by an enlarged part (*anther*), although this stalk is often wanting. The anther contains one, two or four cavities (locules or "cells") in which a powdery mass (*pollen*) is located. The so-called cells are not to be confused with the cells of the plant tissue. The gynœcium and andrœcium, which are both necessary for the production of good seed, are termed the *essential organs* of the flower. Ordinarily each stamen represents one foliar unit. When many stamens are present, this increase in number is brought about in one of three ways: by an increase in the number of whorls of stamens (Caryophyllaceæ, Rosaceæ) or an increase in length of the spiral (Ranunculus), by the conversion of petals into stamens, or by a breaking up of each individual stamen into many (St. John's-wort). The first method is by far the most common. In the last method, the origin is usually betrayed by the aggregation of the stamens in fascicles. Normally both filament and anther of each stamen is free from its neighbors, but in some cases the filaments are all joined into a tube around the pistil (*monadelphous*) as in the hollyhock, or into two groups (*diadelphous*) as in the pea family. These two groups are usually very unequal in the pea tribes, nine stamens being united while the tenth is free. In other cases the anthers may be coherent while the filaments are free (*syngenecious*), as in the Compositæ. In the Sterculiaceæ, the filaments or tube of filaments are variously toothed, crested or otherwise modified; while in the Orchidaceæ they are fused with the style to form the so-called *column* or *gynandrium* of the flower. In the milkweeds, each stamen bears a cornucopia-like appendage which together form the *crown.* In Viola, two of the filaments bear nectar-spurs.

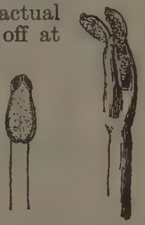
1517. Compound pistil of catnip.
Showing 4-parted ovary, long style, 2 stigmas (*s*).

1518. Head of simple pistils in hepatica.

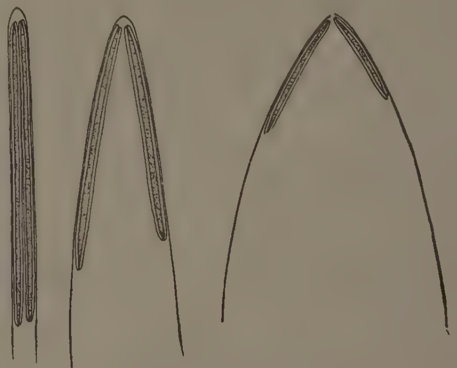
The anthers are usually oval or oblong bodies fixed to the filament by the base (*basal*), or by the center (*versatile*). At maturity they contain normally two pollen-sacs separated by a sterile tissue (*connective*) which is a prolongation of the filament. The anther-sacs are sometimes four in number, sometimes reduced to one through fusion. The walls of the sacs contain a peculiar fibrous layer by the hygroscopic properties of which they are enabled to curve back, thus opening the pollen-chamber along definite prearranged lines and allowing the pollen to escape. The dehiscence is usually by a longitudinal slit, but it is frequently by terminal pores as in the Ericaceæ, or rarely by transverse slits. In Vaccinium, the pores are carried aloft on long tube-like extensions of the anther, while in Berberis the pores are provided with an uplifting trap-door.

1519. Compound pistil of a St. John's-wort. It has five carpels.

The pollen-grains are normally spherical or oval cells in which the two or three nuclei representing the male gametophyte are found. The wall consists of a delicate inner layer (*intine*), surrounded by a thicker cutinized layer (*exine*) which is either smooth or externally sculptured in various ways. Specialized places in the extine serve as germ-pores through which the pollen-tubes easily emerge. These pores are sometimes provided with actual lids (pumpkin and squash) which pop off at the proper time. The pollen in the Orchidaceæ and Asclepiadaceæ is more or less waxy and coheres into one or several masses (*pollinia*). The pollinia are in many cases produced into minute stalks which connect with a sticky gland that is designed to become attached to visiting insects. On the departure of the insect the gland, together with the attached pollinia, is carried away to the next flower. The pollen-grains of orchids, heaths and a few other plants are composed of two to four cells (*compound*).

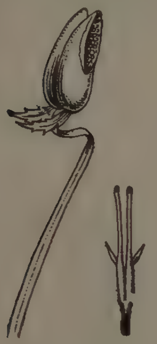


1520. Anthers, showing dehiscence; azalea on left, barberry on right.

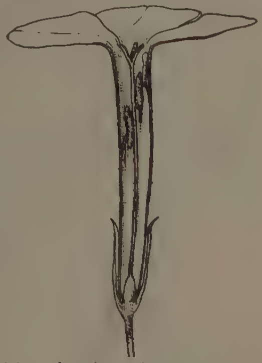


1521. Transitions from stamens to petals in the water-lily.

Corolla (Figs. 1523–1527).—Outside the stamens is found a whorl of flat leaf-like usually colored organs termed *petals* or collectively the *corolla.* The petals are usually in one whorl and follow the numerical plan of the flower closely; rarely are they fewer or numerous. They are normally flat or concave colored bodies distinct from one another (*polypetalous*) and regularly spreading from the receptacle. But in many plants the petals are connate (*gamopetalous*) into one structure for a greater or less distance toward the apices. The united part is the *tube,* the lobed border the *limb* of the gamopetalous corolla. The lobes or segments are either all alike and equally placed (*regular corolla*) or they vary much among themselves (*irregular corolla*). If the lobes are united higher up into groups of two and three, as in many mints, the upper more or less erect, the lower spreading, the corolla is *bilabiate* (Fig. 1526). A particular type of irregular polypetalous corolla is the so-called *papilionaceous corolla* (Fig. 1527) found in the pea family and consisting of a *standard*, two lateral *wings*, and a *keel*. A regular corolla is radially symmetrical, possessing an infinite number of planes of symmetry (*actinomorphic*), while most irregular flowers possess but one plane of symmetry (*zygomorphic*). A few possess no such plane (as Canna). Gamopetalous corollas fall into certain types based on the shape of the tube and limb. The more common types are *rotate*, *salverform*, *funnelform*, *bell-shaped*, *tubular*, and *urceolate*.



1522. Stamens of erica (left) and vaccinium.

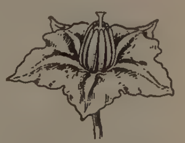


1523. A salver-shaped corolla.

1524. Funnelform corolla of morning-glory.

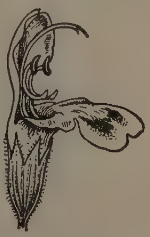
The corolla may be variously colored. White flowers owe their color to light reflected from air which is between the cells of the petals, as shown by the fact that when waterlogged these petals become transparent. Yellows and oranges are usually due to abundant minute color bodies (*chromoplasts*) located within the cells of the petal. Reds and blues are due to colored cell-sap.

Calyx.—Surrounding the corolla is another set or whorl of organs, the *calyx*, the individual organs of which are *sepals*. The calyx is usually composed of as many sepals as there are petals, but in the Portulacaceæ there are but two sepals, while in some plants there are many. In many of the Ranunculaceæ and other families they are colored like petals and replace these organs. In the Easter lily and tulip they are similar to the petals. In the Compositæ the calyx is reduced to scales or bristles or is absent entirely. The sepals are frequently connate (*gamosepalous*), and the resulting structure is often irregular. The calyx and corolla are together termed the *floral envelopes*. If they are similar in appearance, and, therefore, difficult to recognize, as in the Easter lily, they are collectively termed *perianth*.



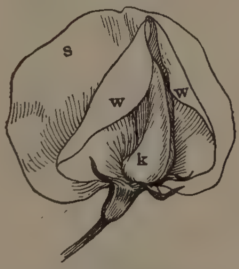
1525. Rotate corolla and connivent stamens of solanum.

Disk (Figs. 1528, 1529).—In many plants a glandular *disk*, or series of glands corresponding to such a disk, is found. When present, this disk may lie either between the stamens and pistil (*intrastaminal*) as is the common case, or more rarely between the stamens and petals (*extrastaminal*). The genus Acer is peculiar in having some species with an intrastaminal disk while in others it is extrastaminal. By some morphologists this disk is considered a fifth set of organs in the flower, while by others it is considered merely as an outgrowth of the floral axis or receptacle on which all other parts of the flower are inserted. The disk is in many cases characteristic of whole families, which led Bentham and Hooker to place these families together in the series Discifloræ. The disk also occurs in other families not obviously related. It forms a ring about the styles in some Rubiaceæ. The glandular cup of Populus and the finger-like gland of Salix are probably to be referred here, although by some they have been interpreted as a reduced perianth. The disk usually functions as a nectary. In shape and structure it is very diverse. It may be cup-shaped, saucer-shaped, annular, regular, or irregular; or it may be of separate glands, either simple or variously lobed. It may line the cup of the perigynous flower or it may be adnate to the surface of the ovary.

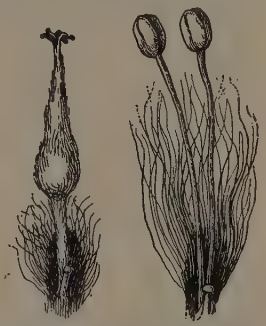


1526. Labiate corolla of salvia.

Receptacle (Figs. 1530, 1531).—The apex of the stem on which the various floral organs are inserted is termed the *receptacle* or *torus*. This is normally a simple club-shaped thickening of the summit of the stem. In the strawberry it is much enlarged and fleshy, forming the greater part of the fruit. In the raspberry it remains on the plant when the "fruit" is removed. In the Compositæ there is a common receptacle for all the flowers of the head, as well as for each individual flower. In the caper family the receptacle is often prolonged upward, forming a stalk for the ovary within the flower (*gynophore*).

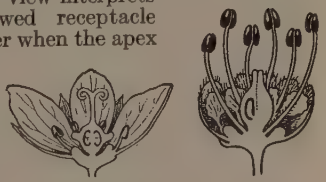


1527. A papilionaceous corolla.—The sweet pea. *s*, standard; *w*, *w*, wings; *k*, keel.



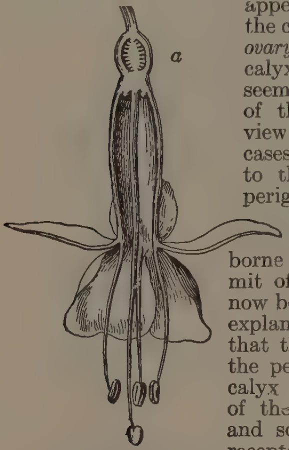
1528. Showing the disk in the willow flower. Pistillate flower at *a;* staminate flower at *b*.

In the Rosaceæ, Onagraceæ, Saxifragaceæ, and in various other plants, the stamens, petals and sepals are *perigynous*, that is they are inserted on the edge of a cup-shaped organ which springs either from below the ovary or from its summit. The view has been held that the gamosepalous calyx here bears the stamens and petals on its tube. Another early proposed view has in recent years gained ground rapidly and is now widely accepted. This view interprets the cup as a hollowed receptacle likened to a glove-finger when the apex is slightly pushed in. The ovary at the bottom of the cup is really apical as usual, while the sepals, petals and stamens, located at the higher margin of the cup,



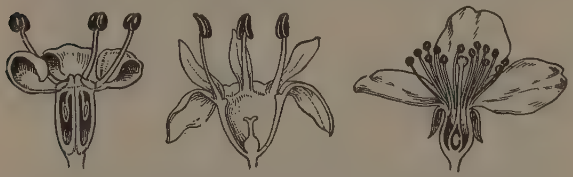
1529. Disks in flowers of maple family.

are as usual inserted morphologically lower on the receptacle. While in most flowers the ovary is inserted on the summit of the receptacle (*superior ovary*), in others, as in the Orchidaceæ, Onagraceæ, Umbelliferæ, Rubiaceæ, and Compositæ, the ovary appears to occupy the center of the club-shaped structure (*inferior ovary*) below the insertion of the calyx, corolla, and stamens which seem to spring from the summit of the ovary (*epigynous*). The view has been held that in such cases a gamosepalous calyx similar to that described above in the perigynous flower has grown fast to the surface of the ovary, and that the other organs are borne on the calyx-tube at the summit of the ovary. The opinion is now becoming general that the true explanation of the phenomenon is that the cup-shaped receptacle of the perigynous flower, and not the calyx has grown fast to the surface of the ovary. In the Onagraceæ and some other plants, the hollow receptacle has not only grown fast to the whole surface of the ovary but projects beyond it so that such flowers have an inferior ovary and are also perigynous (Fig. 1530).



1530. The fuchsia flower in longitudinal section.

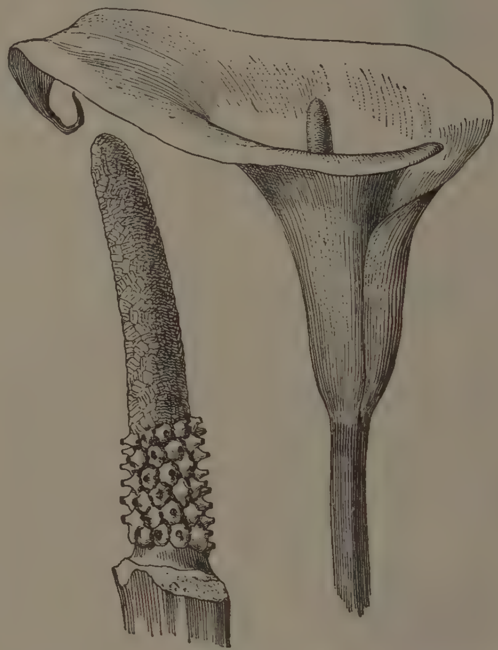
Bracts.—The leaves on the peduncles and upper parts of the stem adjacent to the flower deserve a word. They are often much modified in size, shape and color from the normal foliage leaves, being often much reduced. They sometimes form an involucre around the flower, and are calyx-like, as in hepatica and strawberry. In other cases, they form a showy corolla-like involucre, as in Cornus and Poinsettia, and are then often mistaken for a corolla. In the Arum, a single huge bract (*spathe*) envelopes the entire flower-cluster (*spadix*); these are well shown in Figs. 1532, 1533.



1531. *a*, **epigynous flower;** *b* **and** *c*, **perigynous flowers.**

Incomplete flowers.—Not all of the floral sets described above are always present. The flowers may be *incomplete.* Thus the corolla may be wanting (flower *apetalous*) as in hepatica and anemone, or both calyx and corolla may be absent (*naked* or *achlamydeous*) as in willow and pepper, or the stamens may be wanting (*imperfect* or *unisexual*, pistillate flower) as in willows and oaks, or the pistils may be absent (*staminate* flowers of willows and oaks). At least one set of essential organs is necessary for a functional flower, but in some cases, through specialization for other purposes, both sets may be absent. Thus the marginal flowers of the hydrangea are enlarged and showy for insect attraction, but are *neutral.* In the case of unisexual flowers, the stamens and pistils may be borne in different flowers on the same plant (*monœcious*) as in the oak and birch, or on separate plants (*diœcious*) as in the willow and poplar. In some plants, as in the maple, certain flowers are unisexual while others are perfect, a condition termed *polygamous.*

The plan of the flower.—If the numbers of parts in each set are counted, a certain number will be found to be common to many or all of the sets of the same flower. This is the *numerical plan* of the flower (Fig. 1534). Thus in geranium there are five sepals, five petals, ten stamens, and five parts to the pistil. The stamens, when numerous, are often in multiples of this numerical plan. The parts of the pistil, on the other hand, frequently show a reduction from the numerical plan as exhibited by other parts of the flower. The number of parts in some flowers is so irregular that a numerical plan can be made out only with difficulty, while in some flowers such a plan is apparently wanting.



1532. The great white spathe (and the spadix) of the garden calla.

The members of each floral set are usually inserted all at the same height on the floral axis (receptacle), and are therefore in whorls, although frequently more than one whorl occurs in the andrœcium and rarely in other sets. The parts of one set normally fall between those of the set next outside and next inside, and are said to alternate with these. In some families, as for example in the Ranunculaceæ and Magnoliaceæ, some or all of the organs of the flower are inserted spirally on the receptacle like scales on a pine cone. In such cases there is often a marked intergrading between the organs of the adjacent sets at the boundary line. The relative position of parts of the flower may be graphically indicated by means of a diagramatic cross-sectional plan, called the floral diagram (see Fig. 1534.). Information in regard to the number and union of parts may also be indicated by so-called floral formulæ as follows:

$$\underset{5}{\mathrm{K}}\qquad \underbrace{\underset{5}{\overset{\frown}{\mathrm{C}}}\qquad \underset{5+5}{\mathrm{A}}}\qquad \underset{2}{\overset{\frown}{\mathrm{G}}}$$

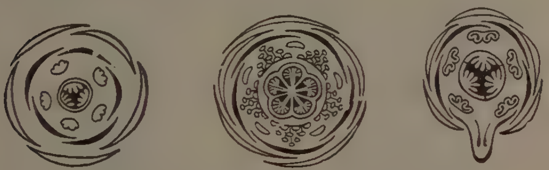
In this formula, the letters from left to right indicate calyx, corolla, andrœcium, and gynœcium respectively. The brackets over the letters indicate a fusion of parts in the same set, while the bracket underneath indicates a fusion of different sets. The above flower would be polysepalous with five sepals, gamo-

1533. Spathe and spadix of Jack-in-the-pulpit.

petalous of five fused petals, have ten stamens in two whorls all inserted on the corolla, and two carpels united into one pistil with a superior ovary.

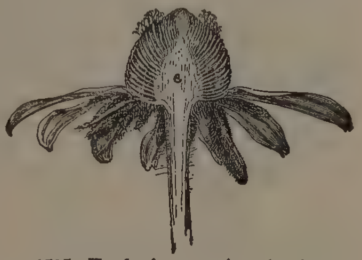
Double flowers.—Occasionally in nature and very frequently in cultivation, the number of petals becomes very greatly increased, often to the exclusion of the stamens and pistils, so that the flower presents a full rosette-like appearance. Such flowers are popularly said to be "full" or "double." The increase in petals is apparently a mutation, but is stimulated by changes in nutrition due to cultivation. Most double-flowered varieties tend strongly to run out. The origin of the extra petals is not always the same. In most cases, as in double hollyhocks and carnations, the stamens and even carpels have been transformed into petals; in rarer cases the extra structures are interpolated organs. Double "flowers" in the sunflower, golden glow, and the like, are simply heads in which all disk-flowers are converted into ray-flowers (see next paragraph).

False flowers of the Compositæ (Figs. 1535, 1536).—The so-called flowers of such plants as the white daisy, sunflower, aster, goldenrod, and dandelion are found on close study not to be flowers at all, but flower-clusters of the type termed *heads*. These heads are remarkably specialized for economy and division of labor. This community of flowers functions as does one individual flower in other cases, and the whole make-up of the head simulates a flower to a remarkable degree. Around the head is a calyx-like involucre of bracts, functioning like a calyx as a protection in the bud. In daisy, sunflower and others there is a corolla-like part consisting of highly modified *ray-flowers* or *ligulate flowers*. The central part of the head in these plants is occupied by *disk-flowers*. The aster, goldenrod, cone-flower and many others are like the daisy, while in the dandelion, chicory, hawkweed and sow thistle the head consists of ligulate flowers only, and in the thistle, boneset and iron weed the head contains only disk-flowers. The morphology of the less specialized disk-flower is as follows: A one-celled, one-seeded inferior ovary is surmounted by a variously modified calyx, which is often wanting, and a tubular five-toothed gamopetalous corolla. On the corolla-tube are borne five syngenesious stamens, and from the summit of the ovary projects a single style which is two-branched above. The ray-flowers have been developed from the disk type in the course of evolution by greatly increasing the size of such a tubular corolla, and by splitting the tube down one side, at the same time flattening out the slit portion. In the sunflower, there was no great change in color as the ray-flowers evolved, while in the daisy and the asters the rays are of a different color from the disk-flowers. Since the involucre performs for the whole head the same function that the individual calyx does normally for each flower, there is no longer any necessity for the calyx. Therefore, following the general rule that a useless structure tends either to disappear or take on a new function, the calyx has become obsolete in some cases while in others it has become modified into scales, awns or bristles (*pappus*) which aid the fruit in dissemination. In many cases the ray-flowers have been sacrificed entirely for insect attraction and have become sterile. By this massing of the flowers, more flowers may be pollinated by one insect visitor, and more easily pollinated. Efficiency and economy run through the whole organization of the composite head to a remarkable degree.



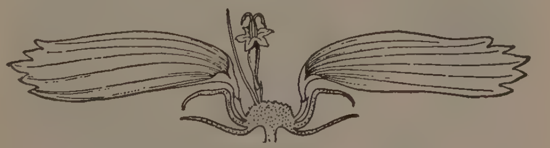
1534. Diagrams of the flower of drosera, vismia and viola.

The biology of the flower.—The flower is a structure developed by plants to promote and safeguard sexual reproduction, primarily in land plants, and to bring about cross-pollination in these plants. The three definite agents of cross-pollination with which the flower is concerned are water, wind and insects. The agent for which the flower is adapted exerts a profound influence on the structure of the flower. Only insect-pollinated flowers are normally showy. Water- and wind-pollinated flowers are usually green and small, with often a total loss of corolla or of both corolla and calyx. The pollen in such plants is produced in abundance to make up for great loss, as it is wafted indiscriminately through the air. Water plants usually flower at the surface and are wind- or insect-pollinated. The true water-pollinated or hydrophilous plants are few in number. Naias, Zannichellia, Zostera and Ruppia may be mentioned, all of which belong to the Naiadaceæ. In Zostera, the pollen-grains are long and spiral as a further adaptation to water-pollination.



1535. Head of composite, showing receptacle at *e*, bearing the disk-flowers. The long rays are shown, and beneath them the hairy involucre.—Rudbeckia.

Wind-pollinated or anemophilous flowers (Figs. 1537, 1538) are very numerous. Elodes and Vallisneria (eel-grass) among aquatic plants may be mentioned. Vallisneria is remarkable because the staminate flowers break off before anthesis, rise to the surface, expand, and are floated about by the wind, the three reflexed sepals acting as floats which cannot be upset. The pistillate flowers are attached to long peduncles which extend to the surface of the water, whether it is shallow or deep. The pistillate and staminate flowers are so shaped that when the two float together the stamens are in exactly the right place to touch the stigmas. After pollination, the peduncle coils up and the fruit matures under water. The catkin-bearing trees are all anemophilous and have very much reduced flowers. The willows are both wind- and insect-pollinated. Among herbs the grasses, sedges, rushes, and sorrels (Rumex) are wind-pollinated. Interesting in this respect is Thalictrum (meadow-rue) of the Ranunculaceæ, the flowers of which are wholly green and insignificant with large exserted anthers and abundant pollen and feathery stigmas. It thus exhibits perfectly the various adaptations to wind-pollination in a family that is normally insect-pollinated and has showy flowers. The time of flowering of wind-pollinated flowers often shows a distinct relation to efficiency. The wind-pollinated trees and shrubs bloom in early spring before the leaves interfere with the passage of pollen through the air. The grasses and other herbaceous anemophilous plants bloom before the tall growth of late summer has matured, at which time plants are mostly insect-pollinated. The pollen-grains of anemophilous plants are nearly always smooth and very light, and usually con-



1536. Parts in the head of a coreopsis.

tain starch as a reserve food instead of oil. This pollen is capable of withstanding greater desiccation than is the pollen of most insect-pollinated flowers. In the pines, each grain is provided with two air-sacs to increase the buoyancy and to expose greater surface to the wind.

1537. Wind-pollinated flower of juncus. (Enlarged)

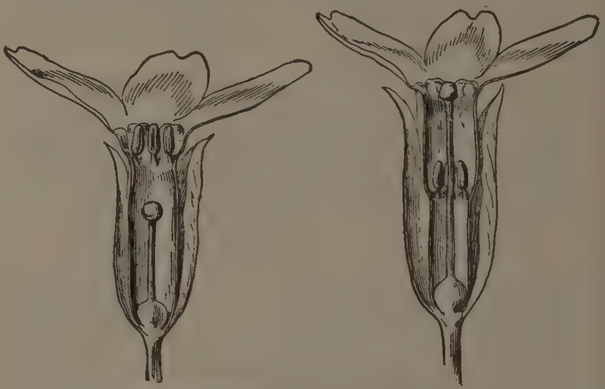
Insect-pollinated or entomophilous flowers must meet two distinct problems: they must entice the insect to the flower; and they must guide the insect in such a way that cross-pollination will be assured. The attractive agents are four in number,—color, honey, scent, and abundant pollen (for pollen-eating insects), but they are not usually all found in one species. Color is provided mainly by the corolla, but the calyx (in Anemone) or even the bracts around the flowers (in Cornus and Poinsettia) may function thus instead. Attempts have been made to show that certain colors are more attractive than others to certain groups of insects. Yellow has been designated as the color for flies and beetles, blue and red for hymenoptera, browns for carrion insects and wasps, and whites for night-flying insects especially. Honey (nectar) is produced in a great variety of flowers and it is a reward for the insect visit. The honey-secreting glands (nectaries) are borne either on the disk or on the petals, but more rarely are they staminal or ovarian. In order that the honey may not be appropriated by undesirable insects which would not effect cross-pollination, it is frequently placed at the end of spurs or grooves which are adapted to the proboscis of the insects for which the flower is adapted. Various markings of the corolla, such as bright eye-spots and dark converging lines, called honey-guides, often direct the insect accurately to the honey, and in such a way that cross-pollination will be accomplished. An interesting case is the violet, where the honey is produced by staminal nectaries but is collected and stored in the spur of the lower petal. To this storehouse honey-guides in the form of purple lines lead. The beard in the throat of the violet flower protects the pollen from rain and also discourages the insect from entering the flower on the wrong side. Scent as a means of attracting insects is very general, and is especially frequent in nocturnal and crepuscular (twilight) flowers. The scent is due to volatile oils produced mainly by the petals. These oily compounds are comparatively few in number and often re-occur in plants that are wholly unrelated. Thus the clove scent is found also in some orchids, and the violet scent is found with slight modification in the flowers of several plants. Flowers that attract pollen-eating insects are often yellow, as buttercups and dandelion, but flowers of other colors are frequently visited at least by bees that carry away quantities of pollen in their femoral pollen-pockets.

1538. Wind-pollinated flower of a grass. —Poa. (Enlarged)

Most pollen is injured by exposure to rain and dew. The grains tend to swell and burst owing to the excessive osmotic pressure. It is for this reason that pollen when studied or germinated in the laboratory must be mounted in a sugar solution approximating the density of the stigmatic fluid. It is not a surprise, therefore, to find that nature has protected the pollen of many flowers from rain, by structural means. Thus, bell-shaped hanging flowers, salverform corollas with a small eye which requires pressure to force a drop of water in, closed corollas of the snapdragon type, beard in the throat, flowers that droop only in wet weather, flowers that close up during rain, and many other contrivances, are adaptations, in part at least, for the protection of the pollen.

The protection of the honey and pollen from unbidden insect guests and the safeguarding of the flower from self-pollination by such insects, has led to various protective devices. The closed throat of the toadflax and snapdragon, the small eye of the salverform corolla, the beard in the violet, setose peduncles and stems over which insects can walk with difficulty, glandular peduncles and bands of viscid matter which serve as a sort of sticky fly-paper to prevent wingless insects from reaching the flower, are all adaptations of this nature. Remarkable in this respect is the teasel, which has connate-perfoliate leaves. These leaves form a basin around the stem at each node. The basins fill with water during each shower, and, as the water will not evaporate for several days, there is a veritable moat around the stem at each node which climbing insects cannot pass.

Cross-pollination is frequently rendered more certain by various mechanical devices. Thus a device of great efficiency found in many plants is the separation of stamens and pistils in different flowers (*diclinism*) which renders self-pollination impossible. In this respect, the diœcious plant is the most perfect type. Diclinism is especially common in anemophilous plants, in which the pollen is blown about indiscriminately. Another efficient device consists in the early maturation of the stigmas (*proterogyny*) or of the stamens (*proterandry*) before the other sex in the same flower (condition of *dichogamy*). Still another, although much less common device, is the production of two or three types of flowers in the same species in which the styles and stamens are of different lengths (*heteromorphism*). Thus in the primrose (Fig. 1539) one flower may have long stamens and short style, and another flower short stamens and long style (*dimorphic*), so that an insect coming from a long-stamened flower will have pollen on his proboscis at exactly the right height to brush the stigma of the long-styled flower. In *Lythrum Salicaria*, the various combinations between the length of style and of each of the two sets of stamens furnish three types of flowers (*trimorphic*). Other devices are often found. Thus in some flowers the pollen of another plant is prepotent in fertilization over that of the same plant if both are placed on the stigma at the same time. There are also many special structural mechanisms in individual species, a study of which forms one of the most interesting chapters in biology. Here may be



1539. Dimorphic flowers of primula.

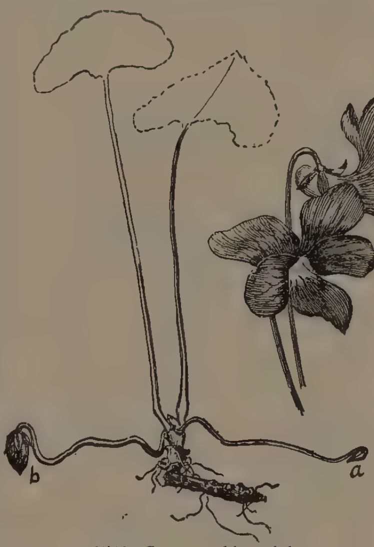
mentioned the wonderful adaptations of the orchid flowers, the catapulting of the pollen of the orchid Catasetum against the insect, the lever-hammering stamens of Salvia, the deliberate stuffing of the Yucca stigma with pollen by the Pronuba moth as she deposits eggs in the ovary, the gall flowers and caprification of the fig, and many other equally extraordinary cases.

Although most plants seem to need cross-pollination and to have structures adapted to this end, there are some in which definite preparation is made for close- or self-pollination. Thus certain plants, as violet, barley, Polygala, Dalibarda (Fig. 1217) and others, produce *cleistogamous flowers*, which are small green apetalous structures often hidden by the leaves or are even subterranean. The calyx of these flowers never opens. The anthers lie against the stigma, and on opening, the pollen is immediately applied to the stigma of that same flower. Seeds produced by such flowers are often much in excess of those produced by the showy flowers of the same species. In the violet (Fig. 1540), cleistogamous flowers are produced in abundance through the summer after the showy flowers have disappeared. Incidentally it is interesting that these flowers in violets are more important in classification than are the showy ones.

Evolution of the flower.—In the Thallophyta, Bryophyta and Pteridophyta there is no flower as that term is here used. The sporophyte shows an increasing complexity through these groups, but there is no differentiation into an organ that could popularly or even technically be called a flower. Among the Gymnosperms, the cones of the Pinaceæ have been likened to a flower with many carpels but with no calyx or corolla, while those of the Gnetaceæ are still more flower-like. The true flower, however, is a structure characteristic of the Angiosperms.

There are two prominent theories in regard to the origin of the flower. First, the foliar theory holds that sepals, petals, stamens and carpels are real leaves modified in the course of evolution from the foliage-leaves of their ancestors. Floral parts are, therefore, metamorphosed leaves. The evolution in this case would have been from below toward the apex of the floral shoot, or from the foliage leaves toward the carpels. Certain teratological conditions have been cited in support of this theory, especially when petals, stamens and sometimes carpels have been replaced by green leaves. This has been considered merely a reversion to ancestral conditions. *Trillium grandiflorum* frequently furnishes cases of this sort. This theory has been exclusively held in the past. Recently another wholly different theory has been proposed by Bower, and is now accepted by very many botanists. This has been termed Bower's sterilization hypothesis. It holds that the foliage-leaves together with the sepals and petals are sterilized sporophylls and that evolution has been from above downward. Specifically it holds that although the simple sporophyte of the mosses consisted as at present of a capsule and seta undifferentiated into stem and leaves, in some special groups of mosses, however, the spore-bearing region around the columella of the capsule became segmented into transverse belts separated by sterile belts. Coincident with this, the exterior of the capsule became lobed in such a way that each fertile belt came to lie in the axil of a lobe. From this it is easy to postulate an increase in size of the lobes to form the scale-leaves of the club-mosses and selaginellas, and an increase in specialization of the fertile belt to form the axillary sporangium of these plants. It is but a step now to the angiospermous flower, in which some of the sterile sporophylls have become modified into petals and sepals instead of leaves. The demand for a large independently growing sporophyte is thought to have led to the sterilization of the sporophylls. According to this theory, leaves are recent rather than primitive structures. The sterilization theory has the advantage of being more in accord with modern knowledge of the evolution of organs in these groups.

Floral evolution within the angiosperms is also difficult to follow and botanists differ as to its course. It is by many held that the most ancient type is the acyclic type as represented by the Ranunculaceæ, Magnoliaceæ and the like. Another although gradually diminishing school holds that the simple flowers of the Gramineæ among the monocotyledons and the Amentiferæ among the dicotyledons are the most primitive. The high specialization of other parts of these plants and the likelihood that the flowers have been simplified because of the adoption of the wind method of pollination, strongly suggests that these flowers are not primitive but specialized.



1540. Common blue violet.

The familiar flowers are shown, natural size. The corolla is spurred. Later in the season, cleistogamous flowers are often borne on the surface of the ground. A small one is shown at *a*. A nearly mature pod is shown at *b*. Both *a* and *b* are one-third natural size.

The flower from standpoint of comparative morphology.—The newer evolutionary morphology has brought about changes in viewpoint in regard to floral parts, and a new terminology has arisen. According to present knowledge, there is in some algæ and in all bryophytes, pteridophytes and spermophytes a definite alternation of two generations or phases in the life-history of each plant, separated by a unicellular condition of the organism. One of these, the more primitive, bears only sex-cells (eggs and sperms) called *gametes* and is termed the *gametophyte*, while the other bears spores only and is termed the *sporophyte*. These generations have exactly reversed their relative size, complexity and degree of independence as evolution has progressed. The originally independent carbon-assimilating gametophyte of the mosses has become in the higher plants wholly parasitic on the sporophyte and is entirely lacking in green color. On the other hand the sporophyte, represented in the mosses and liverworts by the dependent capsule and seta stalk, has become the real plant, bearing leaves and flowers in the higher group. The thalloid reduced gametophyte of the ferns is termed a *prothallium*, bearing sperm-cells in *antheridia* and an egg-cell in an *archegonium*. This prothallium has become differentiated in the more specialized family Selaginellaceae into two types differing in size and complexity of structure, and originating from spores of different size. The large type of spore (*megaspore* or *macrospore*) gives rise to the large female prothallium which bears the archegonia; and the small spore (*microsspore*) gives rise to the small male prothallium bearing only a single antheridium. The prothallia of both sexes are very much reduced and permanently inclosed within the spore wall. In the flower-bearing plants, the reduction and dependence of the gametophyte have been carried much farther. The male gametophyte or

male prothallium is inclosed in the pollen-grain and the female prothallium within the embryo-sac. The spore-bearing chamber or chambers (*sporangia*) corresponding to the capsule in the mosses are borne on leaves (*sporophylls*) in the ferns and fern allies. If these terms used for the mosses and ferns are now applied to the organs of the higher plants the terminology will be as follows: Stamens, *microsporophylls;* anther-chambers, *microsporangia;* pollen-grain, *microspore;* nuclei within pollen-grain, *male prothallium* (male gametophyte); carpel, *megasporophyll;* ovule, *megasporangium;* embryo-sac, *megaspore;* cells within embryo-sac except embryo, *female prothallium* (female gametophyte); the embryo growing from the fertilized egg is the *daughter sporophyte.* A mature seed, therefore, contains parts of three generations; seed-coats and nucellus, if present=sporophyte; endosperm (according to one interpretation)=gametophyte; and embryo=daughter sporophyte. This terminology is now gaining ground over the old in morphological circles for it shows the relation of the flower to organs in the lower groups.
K. M. Wiegand.

FLOWER-DE-LUCE. The origin of the Fleur-de-lis of the French coat of arms is not known. By some it is supposed to represent the head of a spear, by others the flower of a lily. It has also been derived from the points of a crown and from several animal forms, as bees and toads. Apparently, the iris has nothing to do with the heraldic Fleur-de-lis. This name as applied to iris is of later origin and of a purely botanical significance, referring chiefly to *I. germanica.* See under "Fleur," Larousse, Dictionaire du XIX Siècle, 8:450.
H. Hasselbring.

FLOWER-FENCE, BARBADOES: *Poinciana pulcherrima.*

FLOWER-OF-AN-HOUR: *Hibiscus Trionum.*

FLOWERING MAPLE: *Abutilon.*

FLÚGGEA (for Fluegge, a German botanist of early 19th century). *Euphorbiàceæ.* Tropical shrubs, sometimes cult. in the greenhouse: lvs. alternate, simple, entire: fls. apetalous, the staminate in axillary clusters, with imbricate calyx and rudimentary pistil, the pistillate borne singly, and with a lobed disk present, styles slender—ovules 2 in each of the 3 cells: seeds grooved on the inner face.—Six species in the Old World tropics. Related to Phyllanthus. One species, *F. leucopy̆rus,* Willd., with orbicular to obovate lvs. and edible white berries has been intro. to cult. in Eu. It is a bushy shrub from Asia south to Austral. and is said to need rich mold and moist high temperature. Prop. by cuttings.
J. B. S. Norton.

FŒNÍCULUM (diminutive from the Latin for *hay,* because of its odor). *Umbellíferæ.* About four species of annual, biennial and perennial herbs, spread from the Canaries to W. Asia, one being the Fennel of gardens (which see). Glabrous, often tall: lvs. pinnately decompound, the segms. linear or filiform: fls. yellow, in compound umbels, the calyx-teeth obsolete, the petals broadish, emarginate: fr. oblong or ellipsoidal, not laterally compressed, the carpels half-terete, ribbed and flattened. **F. vulgàre,** Hill (*F. officinàle,* All. *F. Fœnículum,* Karst.), of S. Eu., the fennel, is a perennial of short duration, cult. as an annual or biennial for its aromatic seeds and lvs.: erect and branched, 3–5 ft.: lvs. 3–4 times pinnate, the ultimate segms. very narrow and thread-like and rather stiff in the wild and in dry places but very slender when cult., the petioles broad and clasping: umbels large, of 15–20 or more rays. Often run wild.—Under cult., the petiole has become broad and sheathing and other changes have taken place. What are considered to be horticultural forms have been described as distinct species: var. **piperìtum,** Hort. (*F. piperìtum,* DC.), the carosella of S. Italy, the young sts. of which, inclosed in the sheathing petioles, are eaten raw in the early season; var. **dúlce,** Alef. (*F. dúlce,* Mill.), the finocchio or Florence fennel, a low-growing condensed plant, with very large lf.-bases.
L. H. B.

FOKIÈNIA (named after the Chinese province Fokien where the tree grows). *Pinàceæ.* A tree intermediate in its characters between Chamæcyparis and Libocedrus, resembling the latter in the foliage and in the seeds having 2 very unequal lateral wings; the cone is subglobose and composed of numerous peltate scales, each bearing 2 seeds.—One species in Fokien. **F. Hódginsii,** Henry & Thomas (*Cuprèssus Hódginsii,* Dunn). Tree to 40 ft.: branchlets much flattened, the lateral lvs. with spreading acute apex, green above and with white markings below: cone 1 in. long, ripening the second year. G.C. III. 49:66, 67.—Suited only for cult. in warmer temperate regions.
Alfred Rehder.

1541. House constructed without rafters.

FOLIAGE PLANTS. A term used to designate plants that are grown for the general effect of their foliage rather than for their flowers. The term is indefinite. In some cases, and more correctly, it is used for plants with unique or interesting leaves—usually colored—as coleus, Rex begonia, peperomia, calathea, farfugium. In other cases it is used to designate plants of full foliage and graceful habit,—plants that are prized for their general habit quite as much as for the characters of the individual leaves. Of this latter class, ferns, palms, grevillea, screw pine, araucaria, fatsia, ricinus, are leading examples. The latter class contains the most popular commercial subjects, and they are much used in room and table decorations. The plants are often rented for use in temporary decorations. For the culture of foliage plants, refer to the various genera.

FONTANÈSIA (after Réné Louiche Desfontaines, prominent French botanist, 1752–1833, director of the botanical garden at Paris). *Oleàceæ.* Shrubs grown for their handsome foliage.

Deciduous, glabrous: branches quadrangular: lvs. opposite, short-petioled, entire: fls. perfect, small, in axillary clusters forming terminal leafy panicles; calyx minute, 4-parted; petals 4, narrow, small; stamens 2, exceeding the petals; ovary superior, usually 2-celled; stigma 2-lobed: fr. a flat, winged nutlet.—Two species in W. Asia and China.

These are slender-branched shrubs with rather narrow leaves and small whitish flowers in short terminal panicles. They retain the foliage unchanged until late in fall, and are well adapted for shrubberies, growing in any good garden soil. *F. Fortunei* is hardy as far north as Massachusetts, *F. phillyræoides* only half-hardy. Propagation is readily effected by greenwood cuttings under glass in early summer; also by layers and by seed.

Fórtunei, Carr. (*F. phillyræoìdes* var. *sinénsis,* Debeaux. *F. califórnica,* Hort.). Shrub, to 15 ft.: lvs. lanceolate or ovate-lanceolate, acuminate, shining, quite entire, 2–4 in. long: fls. in axillary and terminal clusters, forming a narrow, leafy panicle: fr. broad, oval or ovate, ¼–⅓in. long. May, June. China. R.H. 1859, p. 43.—Sometimes united with the following, to which it is superior by its more vigorous growth, the darker and larger foliage, and by the greater hardiness. In China it is used as a hedge plant and may be recommended for trial in this country.

phillyræoìdes, Lab. Shrub, to 10 ft.: lvs. ovate-lanceolate or narrow-elliptic, mostly with rough, minutely denticulate margin, 1½–2½ in. long: fls. and frs. like those of the preceding species. W. Asia. L.B.C. 14:1308. Var. **angustifòlia,** Rehd. (*F. angustifòlia,* Dipp.). Lvs. narrow-lanceolate or oblong-lanceolate.

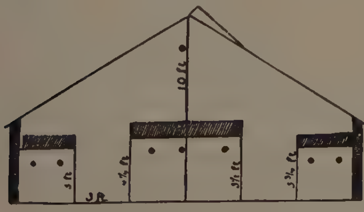
Alfred Rehder.

FORAGE PLANTS are mentioned only incidentally in this work, as they belong to agriculture rather than to horticulture. They are mostly grasses and leguminous plants, and have a very large special literature, much of which can be secured from the United States Department of Agriculture, Washington, D. C., the various experiment stations, and separate books. Some of the forage plants are of interest to horticulturists as green-manures and cover-crops.

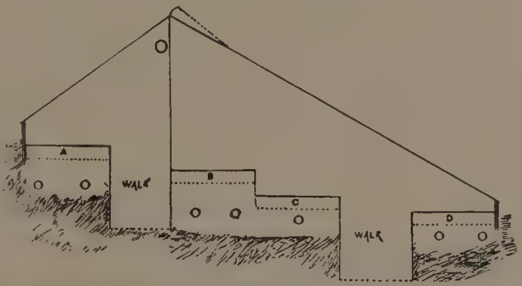
FORCING. The word forcing is variously used. Properly, it should designate the growing of plants outside their usual or normal season. This distinguishes forcing from the ordinary purpose of the glasshouse, which is to imitate the usual season in which plants grow. For example, begonias are not forced: we endeavor to protect them and to give them the season and the conditions under which they grow in the wild. Carnations when flowered in the winter are forced, because we transpose their seasons. Chrysanthemums blooming in October and November are not forced: they are only protected. Sometimes the word forcing is used in a very special sense, to denote the production of flowers from bulbs or tubers in a very short time under the influence of a very high temperature. Thus, the lily-of-the-valley may be placed in a temperature of 90° or above, and the large buds be forced to throw out their flowers before the plant secures a firm foothold on the soil.

A forcing-house is a building in which plants are forced; but the term has come to denote a simple glasshouse in which plants are grown only for sale, in distinction from private conservatories, or more elaborate structures used for the display of plants. See *Greenhouse.*

The forcing industry in America is very large. At first it was confined mostly to cut-flowers (which see), but pot-plants, vegetables and fruits are receiving more and more attention. The staple forced flowers are the rose, carnation, violet, lily-of-the-valley, and various bulbs. These are treated under their respective names. Of vegetables, the most important forcing species is lettuce. This is followed by tomato, cucumber and radish. Other vegetables are of very minor importance as forcing products. The growing of fruits under glass is receiving attention in this country. Very little of this fruit-raising is really forcing, however, since the glass inclosure is used chiefly to protect the plants and to enable better care to be given: the fruit does not ripen much ahead of its normal season. Of this category are glasshouse grapes. Strawberries are really forced, however, the whole period of vegetation and bloom being greatly forwarded. Much attention is now given by florists to the forcing of hardy plants; and this is one of the most delightful of horticultural operations for the amateur. Many of our native plants can be forced with the greatest satisfaction, but the business is usually confined to imported stock of florists' plants.



1542. Even span forcing-house, 20 feet wide, heated by steam.



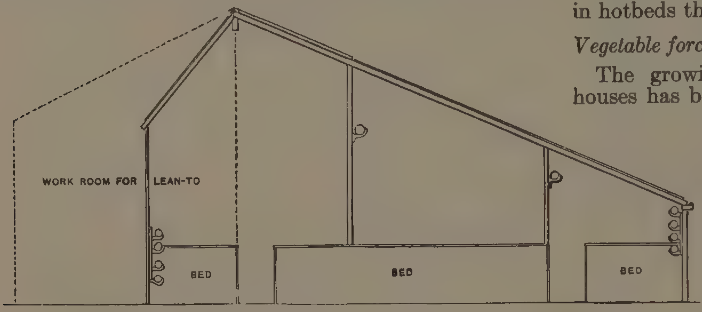
1543. Uneven span forcing-house, 20 feet wide, on a side hill. Heated by steam.

The forcing-house should be of the simplest construction. The plan should secure the greatest amount of light, economy of space and of heating, and directness and simplicity in every operation. The simple sash-bar frame, without rafters (Fig. 1541), is most satisfactory when properly constructed. The side walls should be low and the roof comparatively flat. Often there is no glass on the side walls. Under most conditions, the house should run north and south, particularly if even in span (Fig. 1542), but the lay of the land and the location of existing features usually determine the direction. If the house runs east and west, or if it stands on sloping land (Fig. 1543), an uneven or broken span is usually advisable. The widely different opinions respecting the merits and demerits of the different spans are proof that each is good under certain circumstances. It is the prevailing opinion that, in broken spans, the long roof should be to the south; yet formerly some glasshouses had the short span—which is then very steep—facing the south (Fig. 1546).

In America, all forcing-houses are heated by means of small wrought-iron pipes, which fit together with threads. The old-time cast-iron flues may be employed for conservatories, but they are too bungling for forcing-houses. They do not admit of sufficient modification in layout to adapt them to the long and often crooked runs of forcing-house establishments. The wrought-iron pipes are heated either by steam or water. Each system has its advocates, which means that each has its merits. Steam is less costly to install, since less pipe is required. It also admits of greater variation in the layout. Crooks and obstacles are more easily overcome. In a large establishment, the place may be heated up sooner. Hot water gives a milder heat because the pipes are less hot. Of itself, it is less liable to fluctuations. Theoretically, it is less expensive in fuel; but in practice, the cost of running is found to depend more on the character of the particular system and the operations of the fireman than on the medium itself. When properly installed, steam is as uniform in action as water, and it is adapted to larger areas and to higher temperatures (p. 1403).

Very good shape for a forcing-house in the proportion of breadth to length is probably as 1 is to 4 or 5. The best houses are rarely less than 18 or 20 feet wide, and rarely more than 30 to 35 feet. From 400 to 800 feet is considered to be a good range of profitable length.

Houses of greater length are constructed, but they must be considered as special cases. Parallel houses are often "nested" with good results,—the adjoining houses resting on a common wall. When the various houses are to be used for one kind of crop, the partitions between them may be omitted; a very large space may then be covered with practically one house without the necessity of rearing a high roof. The size of house tends constantly to increase.



1544. Uneven span forcing-house, 30 feet wide. Hot water.

The accompanying illustrations (Figs. 1541–1548) show old and recent styles of American forcing-houses. For further discussion of glasshouses, see *Greenhouse.*

L. H. B.

The forcing of vegetables.

The title "vegetable-forcing" may be applied to any method of growing vegetables which will cause them to mature or to become suitable for use in a shorter time or at a different season than when grown under normal conditions. This includes the growing of vegetables in coldframes, hotbeds and vegetable forcing-houses.

Coldframes.

Coldframes are box-like structures about 6 feet in width and of any desired length. They usually are built to run east and west and with the north side a foot or so higher than the south side. These frames are sometimes covered with muslin but usually with sash in which glass is fastened. The frames serve not only as a protection against cold winds and frost but as a means of catching the sun's rays which may pass through them. In this way, a higher temperature can be maintained in these frames than that which prevails in the open at the same time. Coldframes are used for the purpose of starting crops early and thus growing them to maturity earlier than they can be grown outside, and also for the growing of plants for the field-crops.

Hotbeds.

Hotbeds are similar in construction to coldframes. The chief difference is that in the hotbeds fresh horse-manure is used to supply heat. The manure is firmly packed to a considerable depth, in a pit dug for that purpose inside the frame. Rich garden soil is placed over the manure to a depth of about 6 inches. As the manure ferments, the heat thus formed penetrates the soil above, thus furnishing a satisfactory medium for plant-growth.

Hotbeds are in common use in connection with private gardens in all sections of the country except where freezing weather does not occur. They are used extensively in a commerical way in and near most of the large cities in northern latitudes, and especially such cities as Philadelphia, Cincinnati and St. Louis. Crops are grown to maturity more commonly in hotbeds than in coldframes.

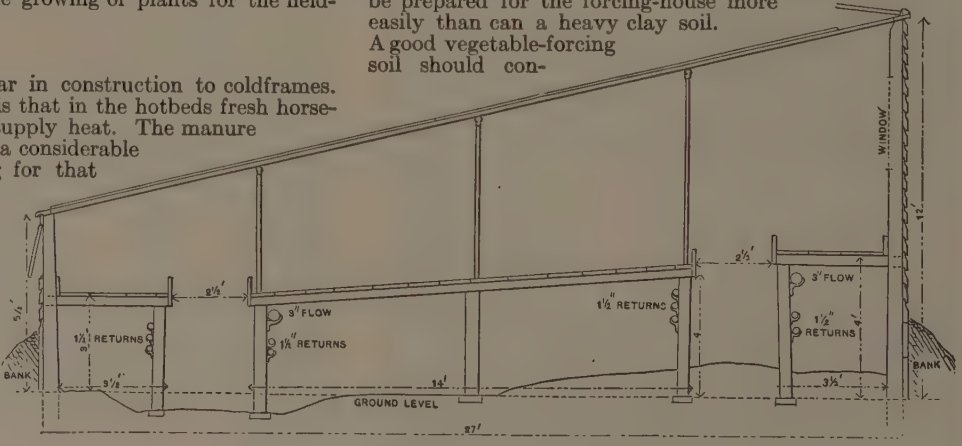
Vegetable forcing-houses. Figs. 1547, 1548.

The growing of vegetables in vegetable forcing-houses has become a very popular and profitable line of work in many sections of the country. The area of glass devoted to vegetables has increased with great rapidity during the last few years. The first section of the country to become noted as a forcing center was Boston, Massachusetts. Soon afterward Grand Rapids, Michigan, became an important vegetable-forcing locality. The Grand Rapids growers did not copy after the Boston growers, however, as their soil, houses, varieties and methods in general differed very materially from those used by the Boston growers.

Vegetable-forcing, as conducted by the Boston growers, was rapidly extended to other places in the eastern part of the United States. The development of the industry was even more rapid and became more extensive in Michigan and nearby states. Grand Rapids methods, with modifications, were followed very largely in this section of the country. The greatest development has occurred in northern Ohio, especially at Ashtabula, Toledo and Cleveland. However, nearly every city of much size, in the northern part of the United States, has in or near it one or more vegetable forcing-houses. The amount of money invested in these houses is enormous. A single acre under glass represents an expenditure of $15,000 to $25,000, depending on the kind of material used and the cost of the material at the time the building was done.

Success in the growing of vegetables under glass does not depend upon climate. Vegetables can be grown in greenhouses in any state of the Union and in any country on the earth in which vegetation flourishes. However, vegetables can be grown under glass more cheaply in moderately warm climates than in cold regions, and more easily where much sunshine occurs than where cloudy weather is prevalent.

As the gardener makes his own soil for the forcing-house, to a considerable extent, the character of the native soil is not so important as is the case with most field-grown crops. However, a sandy soil can be prepared for the forcing-house more easily than can a heavy clay soil. A good vegetable-forcing soil should con-



1545. Lean-to lettuce house, 26 feet wide. Hot water.

tain an abundance of plant-food, should have a good water-holding capacity, be capable of easy working and be as free as possible from weed seeds and disease germs.

A very important factor in determining the financial return from vegetable-forcing is nearness to market. Other things being equal, the closer the grower can get to the consumer the greater the profit. Cheapness of fuel for heating purposes is also very important. If coal is to be used, the hauling should be considered when estimating the cost.

No one thing has more to do with the success or failure in vegetable-forcing than the man who runs the business. To be a success he must enjoy the work. He should have an understanding of the requirements of the crops to be grown and ability to apply himself diligently to his work. Careful attention to details is of greater importance in connection with vegetable-forcing than with any other line of vegetable-growing. Besides being a good grower, he should be a good salesman.

The forcing of lettuce. Fig. 1548.

Head lettuce.—As this crop has special treatment elsewhere, it will need but brief mention here. The Boston growers grew head lettuce from the beginning. They were successful in the growing of it and the markets in which they sold demanded head lettuce. The soil used by the Boston growers is of a very loose texture, being well filled with organic matter. In working over the soil in the houses it is spaded to a depth of 1½ to 2 feet. Large quantities of manure are added at frequent intervals. Some growers practise steam sterilization. Heavy watering is done before the plants are set in the beds. The water-holding capacity of the soil is so great that usually no further watering is necessary until the following crop is to be put in. The lettuce is allowed to develop until the heads become large and solid, when they are cut, trimmed, washed and carefully packed in boxes, three dozen heads in a box. If the lettuce is to be shipped some distance it is put up in cases holding one barrel. It is sold by the dozen heads.

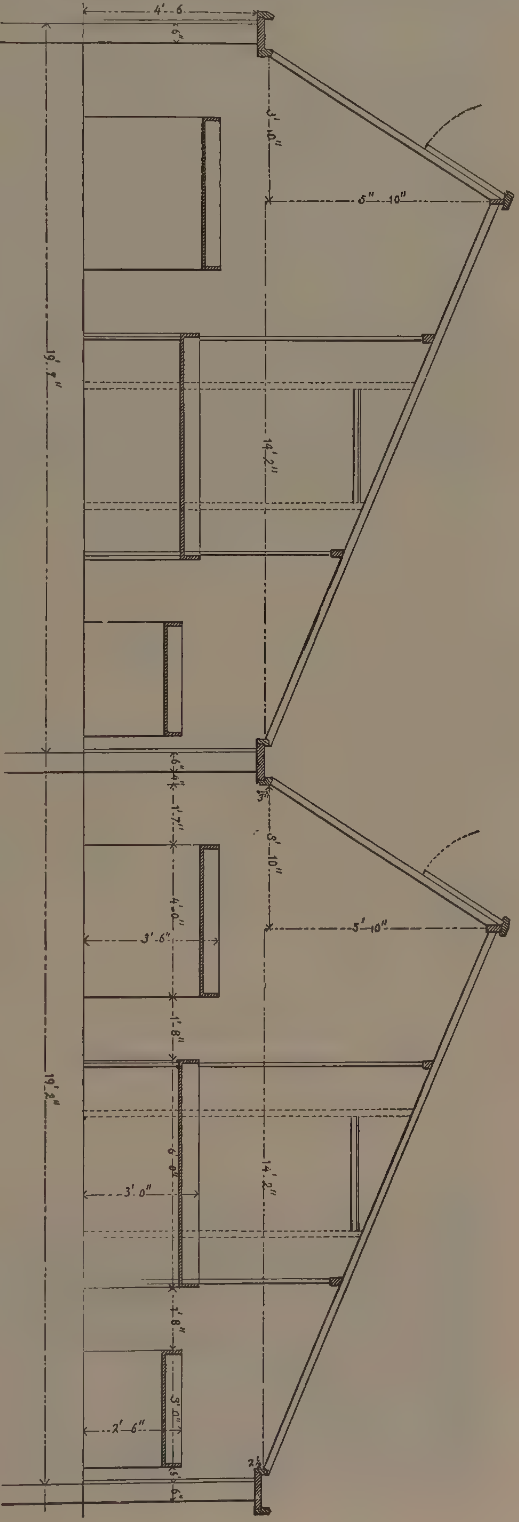
Leaf lettuce.—It was not until Eugene Davis, of Grand Rapids, Michigan, originated and introduced the Grand Rapids leaf lettuce that lettuce-forcing became popular in the middle West. The growing of head lettuce under glass did not prove a success in this region. The cry of "over-production" was heard soon after the forcing of leaf lettuce began and has continued until the present time. With the exception of short periods during the fall months of some years, there has been no over-production of this crop.

Cultural methods.

When leaf lettuce is sold by the pound, the usual practice is to grow three crops of lettuce followed by one of cucumbers or tomatoes. When the lettuce is sold by the dozen, more than three crops are commonly grown before the ground is given over to the other crop. Lettuce sold by the pound is usually grown to a much larger size than when it is sold by the dozen.

The seed for the first crop of lettuce is sown from the first to the middle of August. It is sown in flats or in solid beds, usually broadcast but sometimes in rows. It is sown very thickly and if covered at all with earth the covering is very shallow, not enough soil being used to hide the seeds entirely from view. In warm weather one thickness of heavy brown paper or burlap is thoroughly moistened and placed over the seed as soon as it has been sown and watered. The covering is left on until the seed germinates which will vary from two to five days according to the amount of sunshine and degree of heat in the house. It should not be left on too long as spindling, nearly worthless plants will result. In cold, cloudy weather seeds sown in flats will germinate best if covered with glass for a few days after sowing.

In about a week, in bright weather, and from ten days to two weeks in cloudy weather, the seedlings will



1546. Short-span-to-the-south forcing-houses. A type of house formerly somewhat in use.

be ready to prick off. This operation is tedious and requires deft hands and practice to do it well and rapidly. The plants are separated one from another, care being taken not to injure them, and transplanted into other flats or beds. They are spaced about 2 inches apart each way. All diseased and poorly rooted plants are discarded. The number of plants that can be pricked off in a day of ten hours will vary from 5,000 to 10,000 according to the skill of the operator. Some of the best growers sterilize the soil in which the seeds are sown and the seedlings grown. This not only insures plants free from disease but eradicates all weeds by destroying the vitality of the weed seed.

All the care that is required for the seedlings is to keep the planthouse at the proper temperature, see that the soil is supplied with the right amount of moisture, remove all weeds which appear and stir the soil when necessary to keep it from crusting. The house in which the plants are grown should be well ventilated in order to guard against the damping-off of the seedlings. An occasional smudging with some form of tobacco is necessary to keep the green aphis under control. The cabbage butterfly frequently deposits eggs on fall-grown plants and these hatch into green worms which feed upon the lettuce in the beds. The butterflies should be killed when seen flying near the plants and should be guarded against as much as possible.

In the fall when the days are long and many of them bright, lettuce will be large enough to set in the permanent beds about four weeks after it is pricked off. When lettuce is sold by the pound it should not be set closer than 7 by 7 inches or farther apart than 8 by 8 inches for best results. When sold by the dozen it can be set as close as 5 by 5 inches, although the best distance will depend upon the size of plants which are found most profitable to grow. The first crop of lettuce will be ready to cut, when sold by the pound, in six to eight weeks from the time the plants are set in the permanent beds. It should give a yield of at least three-quarters of a pound a square foot.

The prices that the growers have realized for the first cuttings of lettuce have, during recent years, been rather low. The cost of growing this crop is small, however, as little fuel is needed for heating purposes. The second and third crops will require more time for their proper development than the first. They should give a heavier yield, however, and the prices secured are usually better.

It is very important to have plants of the right size to set in the beds as soon as the ground can be prepared after a crop is out. To be able to do this, it is necessary to make frequent sowings of seed. In large greenhouse establishments, seeds should be sown every day or every other day, while in a small forcing-house a sowing should be made once a week throughout the season. No time should be lost between crops as time is money in the vegetable-forcing business. Considerable time can be gained by making a second transplanting for the second and third crops. The plants should be removed from the flats before they begin to crowd and placed in 2-inch pots. These pots should be plunged in the soil between the newly set plants in the permanent beds. The pots should be placed in the beds as thick again as the permanent plants are set. By following this plan, the plants can be grown to a much larger size without injury than is possible when they are grown only in the flats.

Grand Rapids lettuce will stand a wide range of temperature without serious injury, but the lower the temperature the slower the growth and tougher the leaves, and the higher the temperature the more rapid the growth and more tender the leaves. A low temperature will produce heavy lettuce and a high temperature light lettuce. As long as thorough ventilation is given, little danger of injury from high temperature will occur, but high temperature and closed ventilators invite disaster. The best results are secured when the temperature is held at 45° to 50° at night until the lettuce has attained sufficient height, 8 to 10 inches, when it should be kept as near 45° as possible. The lowering of the temperature at the finishing of the crop will increase the weight considerably. If the houses are arranged so that it is possible to keep but one temperature, a night temperature of 45° to 48° is most satisfactory. The day temperature may vary greatly without injuring the lettuce if the ventilators and heating pipes receive proper attention. Ventilation should be given at all times during the day except when the weather is very cold or stormy. The heating pipes should be turned off whenever the heat from the sun is sufficient to give the proper temperature in the houses.

Sub-irrigation is the most satisfactory method of watering lettuce. The water can be applied at any time through the tile without wetting the foliage. This method is not in general use because of the expense of installation. Water-tight benches or beds are essential for its successful operation.

The overhead or Skinner system of watering is in

1547. A range of forcing-houses.

common use, especially in large establishments. It is a great improvement over the old method of watering with the hose. It is not only more efficient but requires much less time and labor than the hose method. With it, water can be applied in any quantity desired and so gently that no baking of the soil will occur.

Whatever the method of watering, the soil should be thoroughly soaked as soon as the plants are set. It should not be allowed to dry out, as the plants will be damaged by the resulting check in growth. When the water is applied to the surface, the watering should be done only on bright days and early enough in the day so that the lettuce leaves will dry off before night.

Insects and diseases of lettuce.

The one insect that is always ready to make its appearance is the green aphis. Fumigating regularly, at least once a week with tobacco stems or extract of tobacco will keep this insect under control. In case it secures a foothold and one smudging does not do the work, a second the following night will put the aphis under control. Tobacco dust scattered on the surface of the soil before the plants are set will help to repel the aphis.

The cabbage worm is often troublesome, especially on the fall crop. Poisoning when the plants are small, and hand-picking when the crop approaches maturity, are the most practical remedies. Snails and slugs sometimes do damage, but do not as a rule appear when clean methods of culture are practised. Other insects, such as the white fly and black aphis, make their appearance on lettuce occasionally but seldom become serious.

Among the more common diseases affecting lettuce is the drop or stem-rot. This rot acts very much like the damping-off of the seedlings. It is a fungous trouble and can be controlled to a large extent by thorough ventilation. Sterilization of the soil with steam sometimes becomes necessary in extreme cases. There are other less serious forms of rot affecting leaf lettuce, all of which can be kept under control, as a rule, by proper ventilation. Watering at night or during cloudy weather and high temperatures with closed ventilators are practices which will tend to induce attacks of rot.

Another lettuce trouble of common occurrence is "rosette." This is a disease which attacks the roots, retarding and in some instances stopping the growth of the plants. Sterilizing with formaldehyde, used at the rate of two pounds to fifty gallons of water and applying one gallon of the mixture to each square foot of space, has frequently given good results. Sterilizing with steam, while more expensive, is more certain to prove effective. When the lettuce is allowed to suffer from the lack of sufficient moisture in the soil, it will often have the appearance of lettuce rosette. The grower should examine the soil carefully when the lettuce appears stunted in growth to be sure that the trouble is not lack of water instead of a diseased condition before going to the expense of sterilizing.

Cutting and packing lettuce.

There is a certain time in the development of leaf lettuce when it is of just the right size and of the proper degree of maturity to cut for market. This can be determined by the feeling and appearance of the lettuce. When ready to cut, the lettuce plants will feel firm when the hand is pressed gently on the top. If the edges of the leaves show a few brownish spots, the cuttings should be done without delay. The ability to judge just when the lettuce should be cut will be acquired by practice.

Some of the large growers who make a business of shipping lettuce, pack it in barrels. It is placed with the top of the lettuce plants toward the outside of the barrel and, when filled, the barrel is covered with burlap. Fifty pounds are usually packed in an apple or cracker barrel and from seventy-five to ninety pounds in a sugar barrel. The lettuce is protected from frost in cold weather by lining the barrel with paper. In warm weather, holes are cut in the sides of the barrels to admit air and thus prevent heating.

1548. A modern house of lettuce.

Boxes of different sizes but usually holding about a bushel are used by many growers. When the lettuce is to be shipped, the boxes are covered with wooden covers. When it is to be sold on a local market the lettuce is covered with paper or left uncovered. At Ashtabula, Ohio, all of the growers pack their lettuce in small baskets with stationary handles. Three and one-quarter pounds is packed in each basket and the lettuce and basket are covered neatly with paper.

The kind and size of the package and the amount of lettuce put in is not of so much importance as the quality of the lettuce and the care with which it is prepared for market. Bright, clean, crisp lettuce will sell much more readily than tough, dirty lettuce. All dead or yellow leaves should be removed and all dirt washed off.

Marketing.

At some of the large forcing centers the growers are organized for the purpose of marketing their crops. One man is selected to do the selling of the entire output. The growers endeavor to put up a uniform grade of produce, and inspection is provided to see that no inferior stock goes in with that which is up to the standard. This plan insures better feeling among the growers and secures better returns for them than is possible when each grower sells his own products in competition with the other growers.

A grower who has a local demand for all the lettuce he can grow has a decided advantage over the man who is obliged to ship his lettuce some distance. The person having a market within easy driving distance can, if he grows good stock and puts it up neatly, not only cut out the cost of shipping, the commission and much of the package cost that the man who must ship is obliged to pay, but he can also get a higher price for his lettuce, as he can put it on the market in better condition than is possible with shipped lettuce.

Forcing of cucumbers.

Cucumbers are forced very commonly as a spring and early summer crop in many regions. The New

England growers devote a considerable area under glass to cucumbers in the fall and winter months. Eastern-grown cucumbers are sold in western markets at the time of the year at which most of the western growers are devoting all of their glass to lettuce or tomatoes. Some of the vegetable forcers in Illinois and farther west grow cucumbers in the fall and winter.

Varieties.

The long English type of cucumber is not popular for commercial purposes in this country although it is grown to some extent in private greenhouses. The American forcing-man prefers a type of cucumbers for forcing which is of the White Spine order. The first requisite of a good forcing cucumber is prolificacy. It should be from 8 to 10 inches long, even a foot in length not being objectionable, of regular and uniform diameter, not too thick, and free from what some term "neck" ends. It should be dark green in color. The fewer the seeds and the more poorly they are developed the better it will please the consumer.

Cultural methods.

Cucumber seed is planted in pots or flats about four weeks before the plants are to be set in the permanent beds. When planted in pots two to four seeds are placed in each pot. When planted in flats the seeds are sown rather thickly in rows about 2 inches apart. The flat-grown plants are pricked off, when large enough to handle, into pots, one plant in a pot, or into flats about 4 inches apart each way. The plants which are started in pots are not pricked off but they are thinned, when necessary, to not more than two in a pot.

Cucumbers should be kept growing all of the time to get best results. In order to do this, they must be kept in a warm house. The night temperature should be above 60° and may run as high as 70°. The day temperature should run at least 10° higher than the night temperature and on bright days it can go still higher if the ventilators are open. The seedlings should never be allowed to dry out nor should they be watered too heavily as damping off is liable to occur when the soil is too wet. The watering should always be done on bright days. Cold draughts should be avoided as they induce attacks of mildew. Judicious ventilating will insure hardy plants.

The distance apart the cucumbers should be planted depends on the method of training to be used. There are two distinct methods of training, the "A"-shaped trellis and the upright. When the trellis is to be used, the plants are set in rows from 10 to 16 feet apart and from 10 to 15 inches apart in the rows. When the vines are to be trained upright, the plants are set from 2 to 3 feet apart each way, one plant in a place.

The trellises are made of wire or slats and wire which are run across 2 by 4 pieces of timber placed at wide intervals. When the vines are trained upright, strings are fastened to wires which are run above each row, one string to each vine. When training, the vines are simply twisted around the strings and the "feelers" attach themselves and thus hold the vines in place.

Some growers use slender sticks, made especially for the purpose, on which to train the vines. The sticks are 1½ by ¾ inches and from 6 to 8 feet long. A piece about 4 inches in length is nailed across the bottom to keep the stick from sinking into the soil. The tops of the sticks are fastened to wires run parallel to the rows, one wire above each row. The vines are held in place by pairs of nails driven into the sticks at intervals of 12 to 15 inches. One of the nails of each pair is bent at right angles after being driven into the stick and the bent part is dropped onto the other nail after the vine has been placed between the nails.

The pruning of the vines is similar, no matter which method of training is used. All laterals are cut back more or less. One to three female flowers are left on each lateral. Best results are usually secured when the laterals are cut beyond the first female bloom.

Cucumbers in fruiting use an enormous amount of water if it is available. As soon as the supply of water in the soil becomes reduced below the amount required for the maximum growth of the plants and fruit, the number of short runty cucumbers will increase in proportion to the number of long ones. The Skinner system or any other similar system of overhead watering is ideal for cucumbers. Care should be taken to do the watering at a time when the foliage will dry off quickly, especially if mildew or any other fungous trouble makes its appearance. Aside from the fact that the soil must be rich in plant-food, there is no other matter of as great importance as the water-supply. Whether the water be applied a little at a time and frequently or in larger quantities and at longer intervals is not of so much impo tance as the supply itself, which should be sufficient for the needs of the plants at all times.

Pollination.

Some form of artificial pollination is necessary for best results with the White Spine type of cucumber. Hand pollinating is very tedious and is seldom employed in large houses. The usual method is to place a hive of honey bees in the house and let them do the work. In large establishments several hives are required. One strong hive for each half-acre of cucumbers will be ample. When first put in, the bees are quite uneasy but they soon quiet down and make themselves very much at home.

Insects and diseases of cucumbers.

One of the most formidable insects attacking forcing-house cucumbers is the red spider. Some growers are obliged to fight this insect every season. The best way to combat it is to prevent its making an appearance. This can often be done by keeping all of the soil, walks and other places where there is enough dirt to permit of their breeding, moist at all times. When these little animals appear on the plants they can be driven off by spraying the plants thoroughly with water. To be effective, the water must be applied with force and directed against the under side of the leaves.

Another insect which causes much damage to cucumbers is the striped cucumber beetle. The stink-bug may be included with it, as the work of the two insects is very similar in its effect upon the plants. The most serious trouble with these insects does not occur when the plants are small, as they can be protected then, but when they are large. The vines which are damaged by these enemies resemble those injured or killed by the bacterial wilt. If the vines are killed by the wilt, all of the plant dies at one time. When the damage is caused by the bugs, the upper part of the plant or a lateral branch will wilt and dies first, usually but not always followed in a few days by the wilting of another branch or the remaining part of the plant. No effective means has as yet been found for combating these insects. Some growers claim that by keeping the side ventilators and doors closed most of the time the bugs will not get into the houses. To keep them out in some places the ventilator openings would have to be screened. No crops which the bugs work on should be grown near the forcing-houses. When the insects once gain admittance to the houses, they are very difficult to eradicate. The stink-bugs lay their eggs in clusters on the leaves and these should be gathered and destroyed.

The white fly is occasionally serious on cucumbers. The remedy is to fumigate with hydrocyanic acid gas, but as this gas is dangerous to both plant and animal life it is used only in extreme cases.

The green and black aphis occasionally attack cucumbers in the forcing-house. The green aphis can be controlled by fumigating with tobacco. The black aphis usually occurs in patches and can be destroyed by applying strong solutions of tobacco or soap.

Nematodes (eel-worms) often become very destructive to cucumbers. As they work entirely on the roots, their presence is indicated by a weak and stunted growth of the vines. There is no cure for a vine once attacked. Sterilizing the infested soil with steam is the usual method of eradicating them. It is not safe to set plants in an infested soil which has not been sterilized.

Cucumber wilt is a bacterial trouble which often destroys a crop in a few days. There are no satisfactory means of combating it when it becomes established. It is most likely to occur on plants which are weakened in some other way, as by having too much water applied or too little heat. Plants which are kept growing vigorously are seldom attacked by the wilt.

The downy mildew is very partial to cucumbers and often does serious damage. Cold draughts should be avoided as much as possible. Frequent spraying with bordeaux will keep the trouble in check. Another less common but sometimes serious cucumber disease is anthracnose. Bordeaux is the remedy for this disease. Root rot of cucumbers is of occasional occurrence and may be prevented by sterilizing the soil with steam.

Grading and packing cucumbers.

In sorting cucumbers for market they are made into at least two grades. The culls are seldom placed on the market. About the same kinds of packages are used in which to pack cucumbers as are used for lettuce. They vary in size from the sugar barrel to the small basket holding from two to two and one-half dozen specimens. When handled in winter they are usually packed in paper-lined boxes or baskets.

Forcing of tomatoes. Fig. 1549.

Tomatoes are forced under glass at all seasons of the year except during the time they are ripening most freely in the field. The largest area of glass is devoted to this crop in the spring and early summer. There is also quite a large area grown during the fall and early winter. Only a very few growers force tomatoes in the midwinter months.

Varieties.

There is a difference of opinion among growers as to which varieties are best for forcing. In a general way it may be said that for the fall crop the varieties having medium to small fruits are most desirable. Some growers also prefer these kinds for the spring and early summer crop. Other growers like the large fruiting sorts, such as the Stone and Globe for the summer crop. Some markets prefer pink or purple varieties and others red sorts.

Some of the requirements of a good forcing variety are: prolificacy, smoothness in form, meatiness and good flavor. If the fruit is to be shipped it should not be too tender of skin. Some varieties crack more readily than others and those that are inclined to crack should be avoided. Other qualities not lacking, those kinds which are most resistant to disease are to be preferred. Some varieties need less attention in the matter of hand pollinating than others. This is a desirable character and should be given consideration when selecting a variety for forcing purposes.

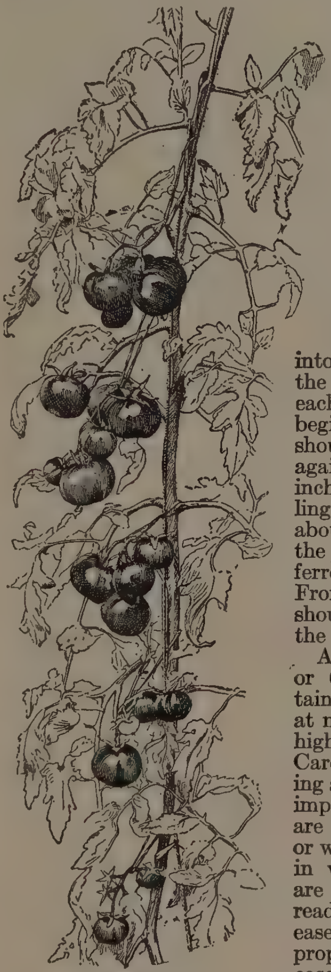
Cultural methods.

For the fall crop the seeds should be sown in June. The best results are secured from this crop when the fruit is all set and well grown before cold weather begins. The crop should begin ripening about the time killing frosts occur and the bulk of the crop should be off by the first of January.

For the spring and early summer crop the seed should be sown in time so that the plants will be ready to set in the permanent beds by the first of March. If a temperature of 60° can be maintained at night, the plants can be grown in two months from the time of the sowing of the seed. Plants set in the permanent places the first of March should ripen fruit about the first of June and should be through fruiting by the middle of August or a little before.

The care of the seedling plants is about the same for the fall and spring crops, except that owing to the difference in the amount of sunshine they can be grown more quickly and easily in summer than in winter. For either crop the seeds are sown thickly in flats or beds and in rows about 2 inches apart. As soon as they are sown the seeds should be covered with glass, paper or burlap to keep the surface of the soil moist. When large enough to handle, the seedlings should be pricked off into flats or beds, spacing the plants 2 inches apart each way. Before they begin to crowd, they should be transplanted again, this time into 2-inch pots. A third handling should be made in about three weeks when the plants should be transferred to 4- or 5-inch pots. From these pots they should be transplanted to the permanent beds.

A temperature of 60° or 65° should be maintained in the plant house at night and at least 10° higher on bright days. Careful attention to watering and ventilating is very important. Plants which are given too much water or which grow in a house in which the ventilators are seldom open will be readily attacked by diseases. Plants which are properly grown are disease-resistant to a considerable extent.



1549. Strand of winter tomatoes.

The spacing of tomato plants which is practised by different forcers is much more nearly alike than is the case with cucumbers. The plants are seldom set closer than 1½ feet nor farther apart than 4 feet. Two by 2 feet or 1½ by 3 feet are good distances. Nearly all tomatoes are trained upright and usually to one stem. When two stems are used, the tops are trained apart a foot or more, making the plant form the shape of a partly opened fan. Strings run from the foot of the vines to wires run above the rows are the usual means of support. By twisting the vines around the supporting strings, only a small amount of tying will be necessary. All laterals or side branches should be removed when small if the plants are trained to one stem. If they are to be trained to two stems, the lowest strong lateral should form the second stem. The lateral just above the first blossom cluster is usually the strongest. All other side branches should be removed. The pruning requires careful attention and consumes much time. If the laterals are allowed to grow to a large size before they are removed, it will, not only require more time to cut them off but they will take needed strength from the main branch.

Pollination.

As honey bees do not work on tomato blossoms it is necessary to do more or less hand pollinating, the amount depending on the time of the year, the number of blossoms open and the varieties grown. If the weather is such that the ventilators can be kept open wide most of the time during the day, frequent and systematic jarring of the plants will be fairly satisfactory. Artificial pollination is more necessary when the plants first begin to bloom than when the amount of bloom is abundant. Some of the English types of forcing tomatoes do not require much attention in the matter of pollinating. However, it is better to be on the safe side and do more pollinating than necessary rather than not enough. The camel's-hair brush is used by some growers and the wooden spoon and spatula with handles 15 to 18 inches in length are used by other growers as a means of transferring the pollen from one flower to another.

Grading and packing tomatoes.

Unless they are to be shipped a long distance, forcing-house grown tomatoes should not be picked until they show considerable color. The more nearly mature the fruits are when taken from the vines, the better the quality. Picking should be done every other day or at least three times a week. The fruit should be handled with care to avoid bruising, as injuries impair the keeping quality of the fruit.

In grading, unless the fruit is unusually rough or too variable in size, only one grade need be made for the average market. All very rough and otherwise inferior fruits should be withheld from the market. Some growers make a fancy grade for special trade. This stock should be of medium and uniform size, even in color and very smooth. The hotels and clubs which give orders for such stock are willing to pay an extra price for it.

Tomatoes are handled mostly in baskets. These are seldom larger than a half bushel and usually considerably smaller. The basket used by the Ashtabula growers is the same as they use for lettuce and holds ten pounds of tomatoes. A very satisfactory package for use in warm weather is the four-basket carrier or crate. The baskets which are put in this carrier hold five pounds each. When properly selected as to size, color, and smoothness, tomatoes packed in this container are very attractive. The chief objection to their use is that they are too much like the package used by the southern tomato-growers and thus not distinctive enough for the forcing-house tomatoes. During cold weather or when the tomatoes are to be shipped a long distance, each fruit should be wrapped in paper to protect it from the frost and to prevent bruising.

Dealers who have not handled forcing-house-grown tomatoes are sometimes slow to pay the price which the stock, if well grown, graded and packed, should demand. When they have once learned that forcing-house-grown tomatoes are of superior quality and will stand up much better than those which have been shipped a long distance and of necessity must be picked green or nearly so, they are usually willing to pay much more for the forcing-house-grown than for the outside-grown tomatoes.

Forcing of radishes.

Radishes have been forced by many growers but they have not become generally popular. This is no doubt due largely to the fact that the growing of them and preparation for market necessitates a large amount of hand labor; and the requirements of the crop are exacting.

The turnip-shaped sorts are most satisfactory for forcing in the forcing-house. The seed should be sown thickly in rows which should be marked 4 inches apart and about ½ inch deep. The Skinner system of watering is very satisfactory for radishes if the watering is properly done. The soil should be kept moist but not too wet on the surface. The watering should be done only when the weather is bright. Some growers have found it more satisfactory to allow the radishes to remain quite thick in the rows until a part of them are large enough to market and then pull the marketable ones and allow the others to develop, than to thin them enough when they are small to permit the radishes to mature nearly at one time. This method of thinning will enable the gardener to grow many more radishes in a given area than when the old method is used.

Some of the essential factors in successful radish forcing are: good seed, carefully sown; an abundance of light; plenty of ventilation; sufficient water and heat to keep the plants growing rapidly but not enough to cause damping-off; neatness and cleanliness in bunching, washing and packing.

Other forcing crops.

Space will permit only of a classification of other forcing crops than those previously mentioned. Nearly all kinds of vegetables which are grown in the open can be grown in the forcing-house. Whether it is practicable or not to force a vegetable in a commercial way depends principally on two things: cost of production and market demand.

The following lists include practically all vegetables which are forced commercially, either extensively or to a limited extent. The vegetables included in these lists are divided into two classes, the "cool" and the "warm" plants.

By cool plants is meant those for which the proper night temperature is from 40° to 55° and by warm plants those for which the night temperature should be from 55° to 70°. With either class of plants the day temperature on bright days should be at least 10° higher than the night temperature.

"Cool" forcing vegetables:

Asparagus
Beet
Carrot
Cauliflower
Celery
Cress
Lettuce
Onion
Parsley
Pea
Radishes
Rhubarb
Spinach

"Warm" forcing vegetables:

Bean
Cucumber
Eggplant
Muskmelon
Pepper
Tomato

C. W. Waid.

The forcing of fruits.

The forcing of fruits under glass has increased considerably in recent years and particularly so in the private establishments. Grapes probably occupy more space than any other class of hothouse fruits. Records of cultivating the vine may be traced back some thousands of years. Nevertheless, the greenhouse grape-vine has not been improved to the same extent through systematic hybridizing that many other fruits have been. Some of our oldest varieties still hold a prominent place in the forcing-houses. Some worthy claimants have been added to the list from time to time. Madresfield Court was raised over forty years ago by crossing Muscat of Alexandria with Black Morocco, producing a distinct Muscat grape with the Morocco coloring. Of later introduction may be mentioned Lady Hutt, Appley Towers and a few others which have been tested and have found favor with many growers. Another account of raising grapes under glass will be found in the article *Grape*.

Forcing of grapes.

The vine is of easy propagation. Different methods may be applied for reproducing young vines, such as cuttings or by eyes of ripened wood. Inarching and grafting may also be resorted to. However, the general method of raising young vines is from single eyes. It is advisable to choose wood of the previous season's growth or, when pruning back the vines, to take thoroughly ripened wood with plump eyes. If not ready for propagating, the wood may be heeled in a cool house until needed. The month of January is best for this purpose, for then there is usually a steady bottom heat, which is necessary. A bottom heat of 70°, with a temperature in the house of 65°, is most satisfactory. Furthermore, January-propagated plants allow for a long season to grow on the canes. In preparing the eyes for propagation, about ½ inch of wood on each side of the eye is sufficient. Make a cut on the opposite side from the eye a trifle deeper than the bark, which will callous in a short time after it is placed in heat and roots will emit in two or three weeks. These eyes may be placed in pans, flats or singly in 3-inch pots; when time is no serious object, the pots are decidedly to be preferred, as the young vine roots are very brittle. In preparing the pots to receive the eyes, half fill them with fibrous soil and fill the top with a fairly sharp sand, enough to cover the wood with the eye just level with the sand. The advantage of having the soil in the bottom is that the roots will strike down and the plants may be repotted, when ready, without a check. They must be kept growing through the summer in a warm moist house and repotted when necessary.

1550. Pot-grown apple tree in bearing.

Inarching may be found valuable at times, particularly if there is a variety in the house that is not desirable. The operation is fairly simple. There are different methods of inarching, although the most successful is with the young growing wood. For example, to inarch a variety with a permanent vine, preparations should be made the year previous. Grow the variety desired in a pot, then ripen off as for planting. Whenever the vines are started into growth, bring in the pot vine intended for inarching, about ten days after the heat has been placed in the grapery. Otherwise the pot vine will start into growth before the permanent vine. It is advisable to select shoots of about the same strength, if possible. The shoot that is operated on should be as near the base as possible. To inarch them is just a matter of bringing the two shoots together and tying with raffia. When the cion has united with the green growing shoots, which will be in a short time, gradually cut it away from its own root; also pinch the stock back by degrees to increase the strength of the cion. Usually the cion will grow away rapidly and produce a strong cane by fall so that when pruning time comes the following winter the old cane may be cut away and the new variety will take its place.

Hybridizing.

In hybridizing with the aim to produce new varieties, it is best to select a fairly strong-growing variety for the female parent, choosing the rich Muscat pollen for the male parent. No estimate can be formed as to results from a true cross, as many different varieties will appear. Grapes will produce an abundance of pollen and great care must be taken to avoid self-fertilization. Nature protects the pollen of the grapevine by a cap that surrounds the pistils and stamens, and when the pollen is ripe for distribution the caps are pushed off by the expansion of pistils and stamens, insuring pollination. To cross-pollinate one variety with another, measures should be taken in advance of natural development to prevent self-pollination. Select the bunch to be operated upon a few days before it would begin to flower. Cut away the larger part of the flowers, leaving a dozen or fifteen to be crossed with other pollen. Then secure this bunch in a fine muslin bag, which will prevent any insects from distributing undesirable pollen upon it. The muslin will allow sufficient air for the berries to set, after which it may be removed. The bag is placed around the bunch a day or so before the cap is ready to be dislodged, and careful watch must be kept when the cap begins to loosen. Have a pair of very fine plyers or pincers ready and remove the cap by force, then immediately cut away the stamens before the pollen has time to ripen. This must be executed with great care as the flowers are very delicate. Sometimes the flowers cannot all be operated upon at the same time. If so, place the bunch again in the bag and repeat the above process. When the stamens have been removed, apply the pollen chosen for the cross. This is best applied to the stigma with a camel's-hair pencil. Repeat until the whole have been gone over carefully. By using these precautions, the bunch cannot become contaminated with undesirable pollen. Grape seed will germinate very readily, although it should be sown soon after ripening as its germinating power is weakened if kept any great length of time.

Vine borders.

Good drainage is absolutely necessary for the successful cultivation of grape-vines. They will not resent an abundance of water while in active growth, in fact they demand it, but a border which the water cannot pass through freely will be found a serious difficulty. It is well in finding a location to choose, if possible, a site on elevated ground, as the drainage from the border can be carried off with less expense than in a low place, without the trouble of the drain-pipes becoming stopped up. A vine border will last for years and the advantage of a well-made border, even though expensive in building up, will be manifest in the better fruit produced.

A grapery may be supplied with both outside and inside borders, although it is not necessary. Neither would it be advisable for early forcing, for the reason that many of the roots would be out in the cold soil at quite a contrast from the ones inside. But for mid-season or late, there is no objection to this method. In fact, vines that have access to an outside border will keep healthy and vigorous several years longer than when confined wholly inside. However, an inside border will last for at least ten or fifteen years. This must be decided before the house is built as, for an outside border, the walls must be erected on arches to allow the roots access outside. One advantage of this method is that the vines do not require such close attention as when depending entirely upon the inside border. However, at present the larger number of graperies are built with inside borders only. The first thing to be done is to excavate at least 3½ to 4 feet for the border. Assuming it to be a span-roof house, lay a drain down the center, allowing enough fall to carry off the water. Use 3-inch pipes and provide openings along every 20 feet or so to take away the water. After the drain is complete, a coat of rough concrete may be placed over the bottom, which will prevent any of the vine roots from penetrating into the subsoil. Over this add a foot or 18 inches of drainage, such as broken stone or brickbats,—anything that will insure a free passage for water. From the drainage to the surface level, there should be about 2½ feet or a trifle over for soil. In some localities it is difficult to secure a grade of soil best adapted for vine-growth, although grape-vines will thrive in different kinds of soil, if not too sandy or too clayey. A good loamy soil is best, virgin loam preferred; or loam that has been in pasture three or four years may be plowed and placed directly into the border. The grass fibers are of great benefit. The vines would make a very satisfactory growth for a year or so without any fertilizing ingredients added. However, this would not be a wise policy and fertilizers of a lasting quality should be used. On that account, farmyard manure should not be used. All fruits require potash, phosphoric acid and nitrogen and therefore these manures should be applied. Do not apply the fertilizers too heavily. It is a simple matter when the vines become thoroughly established to feed from the surface. Bone is one of the very best ingredients to place in the grape border. This may be used in a coarse state or that known as ½-inch bone at the rate of forty or fifty parts of solid to one of bone. Potash may be used in the shape of hardwood unleached ashes, a trifle less in quantity than that recommended for the bone. Toward the surface, a quicker-acting complete fruit-fertilizer may be used. Such a border should grow and produce grapes for many years.

1551. Pot-grown pear tree in bloom.

A span-roof house running north and south is recommended, as a certain amount of sunlight will be had on both sides, whereas in a house running east and west, very little sun will strike on the north side. Either curvilinear or straight span answers the purpose for a private establishment.

Planting vines.

Vines may be planted either in fall or early spring. Early fall-planted stock appears to come away more freely and break stronger than spring planting. Plant the canes about 4 feet apart; there is nothing gained by too close planting. It is immaterial whether one-year-old plants are selected or two-year-old, providing they are thrifty strong canes. They should be shortened back to 2 feet to insure strong growths from the remaining buds, since, if a much longer length of cane is left, they will break away unevenly and weakly. Before planting, all the soil from a ball should be removed and the roots straightened out. Spread the roots out evenly on the border, cover with about 3 inches of soil and firm the soil well around them.

General treatment for forcing.

Grape-vines respond to the forcing treatment readily, although a newly planted grape-house should be brought along with little or no forcing the first season. There would be no advantage in forcing them, as they should not be allowed to produce fruit until the second year, when they will be thoroughly established. However, assuming that the vines are established and grapes are needed from the first to the tenth of May, the house must be started by the middle of December with a temperature of 45° to 50° at night, with a rise of 10° to 15° by day, according to weather conditions, and gradually increasing so that when the grapes are in bloom the temperature will be 65° at night and 75° to 80° by day. If a supply of grapes is demanded up to Christmas or the New Year, three compartments must be accommodated, the midseason house being started two months later and the late house about the first of April. A very important point to be considered is to give the border a thorough watering, for while the vines are at rest they are kept fairly dry. Ventilation or airing is very important, for unless this is attended to carefully serious trouble will follow, such as mildew, red-spider and the like. The heat should be allowed to rise gradually until the maximum is reached in the morning, then kept as steady as possible and toward evening gradually lowered to night temperature.

The best method of growing vines under glass is the single-rod spur system. The spurs should be 15 or 18 inches apart on each side of the rod. Then disbud to one shoot for each spur. As the young growth advances, it must be trained in place by degrees, as the young shoots are very brittle and if brought down too quickly are liable to snap off. The next step is pinching the shoots. The aim is to allow enough growth to cover the trellis with foliage but to avoid crowding. A fairly safe method is to stop the shoot at the second or third leaf beyond the bunch, also pinch all lateral growths at the first leaf.

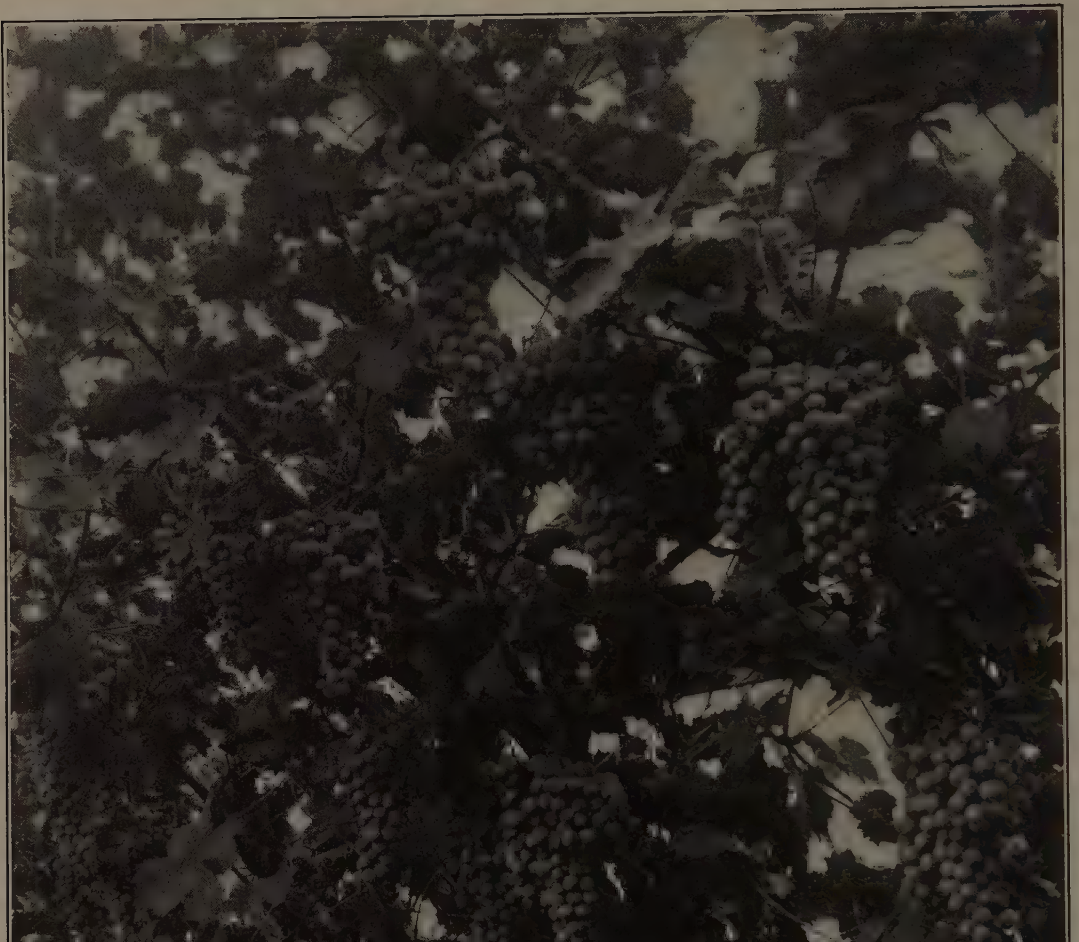
Probably one of the most anxious times with the man in charge is while the vines are in bloom or setting their fruit. Certain varieties will set their fruit much more freely than others. The Muscat family, as a rule, is a bit backward in that respect. A safe method to follow is a steady temperature with a fairly dry bracing atmosphere so that the pollen can distribute itself freely. By gently tapping the bunches around midday, they should set freely. When the berries are about the size of garden peas, they are in condition for thinning. This is a tedious operation, requiring time and patience. The bunch must never be handled with the fingers. Either a stick with a fork or a straight stick to lift the shoulders of the bunch while thinning should be used. The aim is to cut away enough surplus berries to allow the remainder to swell to full size, so that when full grown and ready to cut the bunch will keep the same perfect shape when set on the dinner-table.

Grape-vines, when in a healthy, vigorous condition, are rank feeders. There is no better time to apply food than just after the grapes are thinned and again as they take on their second swelling after the stoning period. This may be applied in the shape of liquid manure water or a complete chemical fertilizer. The grower must use his own judgment in regard to quantity, as so much depends on conditions. A healthy vine can withstand more food than one less robust. Nevertheless, it is much better to feed lightly than too heavily.

A moist humid atmosphere is necessary for grapes while they are growing or from the time they are started into growth until they begin to color, from which time a drier bracing air will be of advantage. At this stage, bottom air may be admitted by degrees during the day, and later, or when ripe, keep bottom air on day and night.

Pruning.

There are two objects in pruning: first, to keep the vines in submission and second, to encourage vigor. For the first season after planting, it would be well to allow the vines to grow freely with very little stopping of shoots. This encourages root-action and if everything has progressed satisfactorily, the canes will



XLIV. Forcing of grapes.—Muscat of Alexandria.

reach the top of the house the first season. When pruning time comes, this cane must be shortened back, allowing only about 5 feet of the season's growth to remain. The same method should be adopted the following year and so on till the full height of vine is secured. Before beginning to prune a grape-vine, one should be absolutely sure the wood is thoroughly ripe. This may easily be ascertained from well-ripened wood, for after pruning the cut will remain perfectly dry and in a few days have the appearance of an old cut. On the other hand, if the wood cuts soft with a fluid on the cut, then the wood is not ripe enough. To produce well-ripened wood from the time the crop is gathered till pruning time, an abundance of air should be allowed in the house and when the foliage has completed its functions a dry atmosphere should be maintained and the vines kept fairly dry at the roots. In the long-rod spur system, it is necessary to prune hard back, otherwise in a few years long ungainly spurs will result. One or two eyes to each spur is sufficient and, with thoroughly ripened wood, there is no danger but that a bountiful crop will follow.

Varieties.

There are many varieties for forcing purposes, although only a selection of the best varieties, early and late, is given here. The Muscat grapes are the finest of all the hothouse kinds. Unfortunately they require a longer season to ripen. Consequently one must rely on earlier-maturing varieties for early forcing. A few canes of Muscats may be planted in an early house and they will be useful after the early kinds are exhausted. It is not wise to depend on thin-skinned Muscats for late use, as there would be difficulty in keeping them in condition any length of time. The following varieties are recommended for early, midseason and late:

Early.—Black Hamburg, Appley Towers, Madresfield Court, White Buckland Sweetwater, Foster Seedling, Royton Muscat.

Midseason house should be devoted wholly to Muscat of Alexandria, which is one of the finest of all indoor grapes. It thrives better in a compartment by itself, requiring a trifle more heat.

Late house.—Gros Colmar, Gros Maroc, Barbarossa or Gros Guillaume, Alicante, Diamond Jubilee, Prince of Wales, White Lady Hutt.

Many others may be added to the list, but these will be found to cover the season and varieties sufficiently for all purposes.

Forcing of peaches and nectarines.

These fruits come next in popularity to the grape and considerable space is devoted to their culture under glass. Great improvements have been brought about in recent years with both peaches and nectarines and a large number of new varieties are constantly appearing for forcing. One of the handsomest forcing peaches is Peregrine. The color is magnificent and flavor all that could be desired, with size sufficient to please the most exacting. Others might be mentioned to show the progress of time.

Cultural methods.

The same style of house that has been recommended for grape-culture will be found ideal for peaches and nectarines, although instead of having the walk down the center of the house, it is better along each side. This will allow planting the trees crosswise of the house on trellises about 6 feet apart, which affords ample space for a well-balanced tree. Also the same arrangements in regard to borders, drainage and so on should be carried out, although a slightly shallower border would be satisfactory. From 2 to 2½ feet of soil would be sufficient; nor is it necessary to make the border quite so rich for peaches and nectarines as for grapes, as the trees would have a tendency to rank growth, a condition that should be guarded against. Peach trees budded on plum stock are superior for forcing purposes. Choose the best trees obtainable for this work. In our climate, if everything goes well, the trees will grow into large proportions in three or four years. Therefore, space should be considered with this in view. A tree that is planted in such a way that the branches are evenly balanced on both sides, causing an equalization of the sap, will insure better results. Assuming the peach-house to be 25 feet in width with the trellis crosswise the house, allowing a walk on each side, each tree would have a spread of about 18 feet. One tree in the center of each trellis is sufficient, which allows ample room for development. If desired, a tree may be planted on each side of the permanent one for two or three years, but must be cut away as the space is needed for the permanent tree. Still another method may be adopted and probably the best, which is placing trees in tubs on each side, then as space is needed they may be moved away, whereas when planted in the border one is likely to leave them too long and crowd the main tree out of shape.

It would not be wise to force newly planted trees to any extent, but rather to bring them along gradually for the first season, when they will be in condition for forcing. If ripe fruit is in demand about the first week in May, the house must be started about the middle of December. The peach tree will come on and develop its blossoms in a comparatively moderate temperature and it would not be wise to submit it to extreme heat artificially. Peach trees delight in fresh air, and will resent a too close humid atmosphere. A temperature of 40° to 45° at night and 50° to 55° by day will suit their requirements at the start. Gradually increase this so that the temperature will range from 50° to 55° at night and 60° to 65° by day or 70° with sun heat when in bloom. After the fruit is set, another 5° may be added. Give plenty of air without lowering the temperature, particularly in cold weather. Give the house a light spraying two or three times a day when the weather is clear until they come into bloom. Do not spray while they are in blossom. After the fruit is set, spraying may be resorted to again once or twice a day according to weather conditions.

Peaches are subject to greenfly. As a precaution after the fruit is thoroughly set, syringe every ten days or so with a solution of whale-oil soap, enough just to color the water. This is an excellent remedy for both greenfly and red spider, both deadly enemies to peach foliage.

The peach tree will produce many more shoots than are needed to furnish the trellis, therefore the surplus will have to be removed. This is best done by degrees rather than removing them all at once, which would be likely to cause a check. A number of shoots may be pinched at the third leaf, which in all probability would form spurs or fruit-buds for the following season. The aim is to allow enough wood to remain to cover the trellis, but to avoid crowding. As the crop advances or before the fruit becomes of much size, thinning of the fruit would be in order. It is a serious mistake to overcrop. If a tree has a tendency to rank growth, a fairly heavy crop would be of advantage. The grower must be governed according to conditions.

Watering and feeding are important. Potash is necessary for all stone-fruits and should be applied in some form, or a complete fruit-fertilizer may be recommended. It is better to feed light and often rather than too much at once. Enough water must be supplied to give the border a thorough watering from top to bottom. Then no more should be given until necessary, for if the soil is not allowed to sweeten up it would be impossible to keep the trees healthy. It is not a good policy to have the trees or borders saturated just as the fruit is ripening. It is better to give them a watering a week or so in advance, which will usually last until the fruit is gathered. The object of this is to improve the flavor of the fruit.

One should not think that after gathering the fruit the house needs little or no attention. The temperature will not need close watching, but the fruit-buds have to form and develop, and good attention to watering and spraying the foliage is a wise step toward success for the following season. Cut away any useless wood after the crop of fruit has been picked, thus allowing the remainder of the wood to become well ripened. Well-ripened wood will withstand any reasonable amount of frost during the dormant state, and fruit-buds will respond when called upon with abundance of healthy strong blossoms. Winter-pruning may be done any time after the trees have cast their foliage. This means removing any weak growths, shortening back extremely strong growth and training the young wood so that it will spread over the space about 5 inches apart.

1552. Pear in fruit under glass.—The Hardy.

Varieties.

For forcing there are many varieties to choose from. The peach crop may be extended at least seven weeks for one house, but if the compartments are at command a season of five months or more may be had by planting early, midseason and late varieties. The following varieties may be relied upon for early, midseason and late:

Early forcing peaches.—Duchess of Cornwall, Duke of York, Peregrine.

Early forcing nectarines.—Cardinal, Early Rivers, Advance, Lord Napier.

Midseason peaches.—Peregrine (Alexander, Noblesse), Bellegarde, Grosse Mignonne.

Midseason nectarines.—Stanwick-Elruge, Rivers, Orange-Chaucer.

Late-house peaches.—Crawford Late, Thomas Rivers, Princess of Wales.

Late-house nectarines.—Newton, Spencer, Humboldt, Victoria.

Numerous other varieties could be added to this list. However this will be found sufficient for all practical purposes.

Pot-fruits.

This method of producing fruit has found favor with many growers throughout the country, particularly in private establishments. It requires no specially built houses for the purpose, providing the house receives full sunlight with abundance of ventilation. There are two or three advantages of this concentrated method of growing: first, the house may be used for other growing crops after the fruit is gathered, as the trees may be placed outside or, as severe winter sets in, they may be stored away in a coolhouse close together until such time as they are needed for bringing into growth again; second, a large variety of fruits is adapted to this method of culture, such as peaches, nectarines, pears, plums, figs and the like. These trees may be grown into either pyramid or half-standard forms. Pyramids, as a whole, make a more attractive appearance in a house than any other form of training. A house for pot-fruits requires about the same treatment as that recommended for peaches planted in a permanent border. Care and watchfulness are required as to watering, particularly when first starting into growth, as at that stage there is not much foliage, consequently an over-abundance of water would have a tendency to sour the soil. Potting the trees is very important. There is no better time for this operation than early fall, or just as they are casting their foliage. Also a serious error is placing them in too large pots or tubs. They should be repotted every fall, but it is not always necessary to give them a larger tub. Often the ball may be reduced and placed into the same-sized tub. The soil should consist of a good fibrous loam used in a fairly rough state, if possible, as this will allow free action for the water to pass off. Firm potting is of great importance. Three parts of soil to one of thoroughly decayed rich manure with a little bone mixed in would be an excellent compost for the purpose. Careful watering after repotting is very important.

When the trees come into bloom, keep a fairly dry bracing atmosphere. Pears and plums will refuse to set their fruit otherwise. As the growth advances, frequent pinching or stopping the shoots should be attended to. Some growths will doubtless be much in advance of others. When the young growths reach the length of 5 or 6 inches, they should be pinched and again when they have extended another similar growth and so on. Usually in the case of pyramid trees, growth will be found more advanced at the top, hence those shoots should be stopped, resulting in more vigor for the lower branches.

Surface-dressing when the fruit is swelling is of great benefit. Either manure or a concentrated fertilizer may be mixed with the soil and added as a top-dressing, but by all means do not apply this until the fruit is swelling away freely.

Pot-fruit that has been properly cared for during the season of growth in regard to pinching and summer-pruning requires little winter-pruning aside from removing the very weakest growths.

Varieties.

The following varieties are the best:

Pears.—Souvenir du Congres, Madame Treyve, Hardy, Fondante d' Automne, Louise Bonne, Conference, Magnet, Pitmaston Duchess, Durondean, Princess.

Plums.—The Czar, Blue Rock, Oullins Golden, Early Transparent, Gage, Mallard, Denniston Superb, Belgian Purple, Golden Esperin, Transparent Gage, Green Gage, Grand Duke.

Figs.—Brown Turkey, Negro Largo, White Marseilles, Violet Sepor.

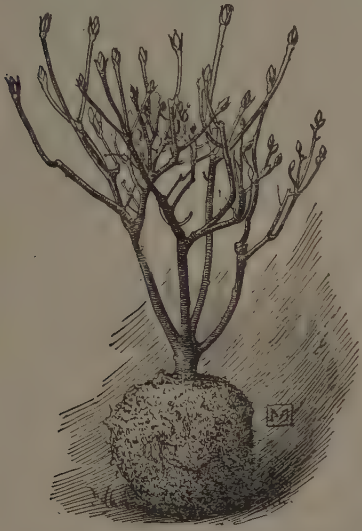
Apples and apricots also may be added, although they are not so profitable as the others mentioned.

Wm. Turner.

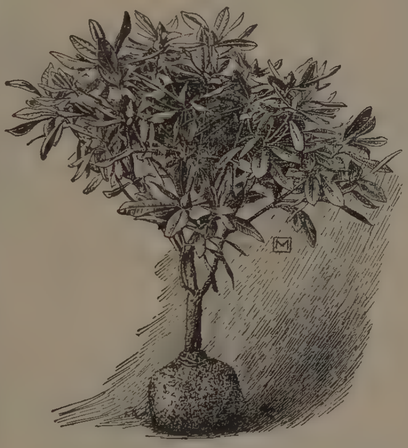
Forcing hardy plants.

Forcing is an economical method of securing large quantities of flowers in winter; it is extensively used by commercial florists for cut-flowers and flowering plants. Plants usually forced are hyacinths, tulips, narcissi and other Dutch bulbs, lily-of-the-valley, astilbe, dicentra, hybrid perpetual and rambler roses, *Deutzia gracilis*, hybrid rhododendrons (*R. sinense*) and Ghent azaleas, tender hydrangeas and lilacs.

This mode of procuring flowers at small cost has always been more or less in vogue among plantsmen, and of late years has received fresh impetus, owing to the heavy demands for decorative plants at Easter. It is not only an inexpensive method of getting flowers, but with most plants, after a little experience, the time of blooming can be easily calculated. The process has limitations, at any rate with our present knowledge of the matter, inasmuch as, with the exception of "retarded plants" and a few bulbs, it is not practicable in late autumn and early winter without the use of ether. It is possible, however, that by using "retarded plants," i.e., plants held over their natural time of flowering by keeping them in cold storage at a temperature sufficiently low to prevent growth, this difficulty may eventually be overcome. Except, however, with lily-of-the-valley, which is admirably adapted to this practice, little is known of the possibilities of this form of forcing; it is hoped that other plants, equally useful, may be treated in this way. It is evident that, on account of the cost of storage, bulky plants could not be handled.



1553. Azalea, received from Europe, now pruned for forcing.



1554. Rhododendron, received from Europe, ready for forcing.

The requirements for successful forcing are: (1) a good knowledge of the plants; (2) proper preparation; (3) a period of rest; and (4) proper care after the plants are brought into heat.

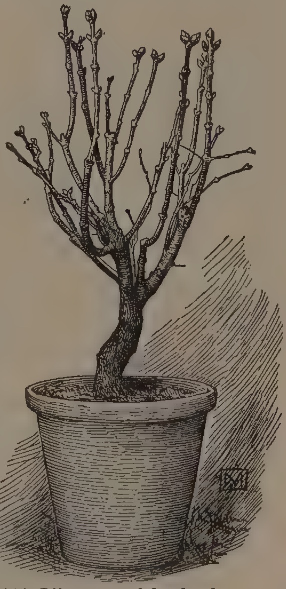
Those plants force most easily which bloom in spring and early summer. Late-blooming kinds, like *Rhododendron maximum*, clethra and *Hydrangea paniculata* var. *grandiflora*, do not give good results. No success is obtained with asters and goldenrod, unless they are retarded. These points must be studied out by the grower.

Trees and shrubs should be specially prepared for forcing by careful cultivation for one or two years before use. They can be planted out-of-doors, with plenty of room to develop, or they can be grown in pots, the latter method being used with vigorous plants, which are apt to run to growth without developing flower-buds. Close pruning is necessary, and root-pruning is helpful. Grafting, which has a tendency to dwarf and hasten maturity, is also used with strong growers. Sometimes both growing in pots and grafting are employed, as in lilacs.

A plant fit for forcing must be compact, both top and roots; economy in space is essential. It is now possible to secure from the French, Dutch and Belgian nurseries many plants grown for this purpose. A few come pot-grown, but most of them are from the open ground: very little of this work is done in American nurseries. Figs. 1553–1555 show the methods of preparing woody plants for forcing.

Herbaceous plants should be prepared for forcing with equal care, and the process may require several years. The removal of the flower-buds and growth, under high cultivation, in close, compact clumps, apparently produces the same results that pruning and grafting accomplish for trees and shrubs. Fig. 1556 shows the root-clump of an herb prepared for forcing.

Plants that have once been forced are commonly thrown away. It is generally cheaper to buy new stock, but lilacs, azaleas, and the like, can be planted out and will recover sufficient strength in two years for a second forcing, or for other use. Some species, like *Viburnum plicatum*, staphylea, and xanthoceras, if grown on in pots after forcing, may be again forced, and seem to do better the second year. This is probably explained by the fact that insufficient preparation was given for the first trial, the first forcing being really "proper preparation" for the second forcing.



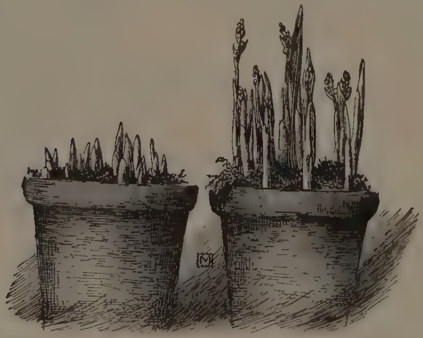
1555. Lilac pruned for forcing.

Hardy plants must have a period of rest for successful forcing, the time required varying in different species. One cannot tell, except by experiment, that Paper White narcissi will force easily in November and December, while the double Von Sion will not; the individual equation of each kind is an element which must be considered. There is a popular notion that freezing will shorten the time for resting, or, at any rate, is conducive to the welfare of the plant. This idea does not seem to stand any practical test. After potting, do not subject the plants to severe frosts (10° to 12° F.), or else the roots, now much exposed, may suffer. The large buds of lilac and rhododendron may also be injured if frozen hard.

Pot the plants as soon as they ripen their growth in autumn, beginning in September with herbaceous stock, and continuing until severe frost. It is possible, but not desirable, to lift some things after the ground is frozen hard. Plants received from abroad are potted on arrival, or, if furnished with a ball like azaleas (Fig. 1553), they can be stored and not potted until brought into heat. Dutch bulbs are boxed or potted as they are received, and buried in the earth or piled in stacks and covered with enough leaves and litter to exclude frosts. Lily-of-the-valley, astilbe and dicentra may be kept in their packing-cases in a cool pit until ready for use. Large plants in tubs and boxes can be covered with leaves and kept out-of-doors, but most plants should be stored in a cool cellar, pit or frame kept at a temperature of 35° F.; a temporary variation of 5° either way does no harm. It is well to delay this storage until as late in the season as possible, but it must be done before severe weather. Plants may be stowed compactly in several tiers if necessary. It must be remembered that no growth is to be allowed while stored; it is their period of rest, and this must be enforced. Good ventilation must be given on bright days and every precaution taken against an accumulation of moisture: if the plants are well watered when put away very little will be required afterwards. Dampness is most serious with evergreens, like kalmia, and such things as *Phlox subulata.* This stock should have the airiest positions; sometimes it can be placed in shallow frames 2 feet deep, which are drier than deep pits. In severe weather the pits are often covered with snow a week or more, but the plants will not suffer if this happens but once or twice during the winter. At such times mice and squirrels will make trouble unless trapped or poisoned.

1556. Dicentra roots prepared for forcing.

Nothing except retarded plants, a few bulbs and one or two kinds of prunus should be brought in before November. December 15 to January 1 is as early as it is safe to begin forcing most hardy plants; it will be found that as the days lengthen the results will be more satisfactory. At first the plants must be kept cool, 45° F., or thereabout. Syringe twice a day until the buds swell: after growth starts the treatment is the same as that given greenhouse plants, and they can be put in a much warmer house if so desired. It is at this time that care in handling, particularly in the matter of heat, makes it possible to time the period of blooming so accurately, but it is impossible to give any general rules satisfactorily to cover these matters.



1557. Forcing lily-of-the-valley in pots.

A few plants, like lily-of-the-valley, can be placed directly in a forcing-box, generally made over the pipes in the hottest house, where a temperature of 80° or more can be maintained. They are first soaked in water for a day or two and then kept in this heavy heat until flower-buds are well developed (Fig. 1557).

Tulips, hyacinths and other bulbs, sometimes an azalea or lilac, can also be hurried up in such a box, but it is dangerous, and not good practice; better and more lasting flowers come with ordinary treatment. Trilliums (Fig. 1558) and various early-flowering wild plants may be forced with satisfaction.

Although no rules can be given for the time required in forcing, it is knowledge not hard to acquire with even surprising exactness. Nothing is likely to require more than three months in houses ranging from 45° to 55° F.—i.e., after bringing in from the pits. A month or six weeks is good time to allow in February and March, but with the same plants and temperatures, more time would be needed earlier; with the advance of the season, the work is quicker and less uncertain. There is a great difference in plants. Rhododendrons (the hybrids) require eight weeks or more, but one species will often bloom in March, within twenty-four hours. Plants like the rose, which must make a growth before the buds form, take more time than *Rhododendron sinense.* The difference between dull and bright weather is an important factor, but with extra firing, or the use of the forcing-box, these matters even up, and the average time of flowering is wonderfully even. In this work, a man with good plant sense is most likely to succeed.

1558. Forced trillium.

The use of anesthetics in forcing.

In the latter part of the last century and early in the present, experiments were begun in Germany, and confirmed in France, England and the United States, in subjecting plants to the influence of ether and chloroform for the purpose of securing better results in forcing. Ether seems, for many reasons, the most practical agent, but, owing to its cost and the extra expense of handling the plants, this process does not appear to be in common use among florists. For a detailed treatment of this subject, the reader is referred to an article by M. Emile Lemoine in the Journal of the Royal Horticultural Society (London), Vol. XXVIII, 1903–4, p. 45. See, also, the article *Etherization,* p. 1146, Vol. II.

In the main, the treatment of plants for this purpose is as follows: A container, which can be hermetically sealed and of the proper size is provided. In it are placed the plants "as dry as possible, in equally dry sand." The temperature of the box is 62° to 65° F. Under the lid is a vessel into which the ether can be poured and the hole sealed at once. It is important to have the ether at the top as its vapor is heavier than air and consequently gravitates downward. Ether, particularly when mixed with air, is very inflammable and lighted matches, cigars or pipes must be kept away. "Thirty or forty grammes of ether are enough for one hundred cubic litres of air: one gramme equals fifteen and one-half grains, one litre equals sixty-one cubic inches." The ether used is "pure sulfuric ether which boils at 95° F." The plants are kept under the influence of the ether for two days; sometimes they are removed for two days and the etherization repeated for the same length of time. Afterwards they are placed in a coldhouse and "treated in the usual manner." Lilacs "were in full flower eighteen days after being placed in the greenhouse," one, "Marie Legraye still earlier." Johannsen made lilacs "flower regularly" the first two weeks in September which had been etherized the first week in August." With other shrubs, such as *Rhododendron sinense* (*Azalea mollis*), *Viburnum Opulus, Prunus triloba, Deutzia gracilis* and some of the spireas, the results were more or less favorable."

Trials with chloroform apparently have been less successful and other anesthetics and stimulants have been found failures.
B. M. WATSON.

FORESTIÈRA (after Forestier, a French physician). Syn. *Adèlia. Oleàceæ.* Sometimes grown as ornamental shrubs.

Deciduous, rarely evergreen trees or shrubs: lvs. opposite, entire or serrate: fls. diœcious, apetalous, with or without calyx, in small, axillary clusters in early spring, before the lvs.; stamens 2–4: fr. a small, mostly black, 1- or 2-seeded drupe.—About 15 species from Ill. south to Brazil and the W. Indies.

The species in cultivation are shrubs with rather small leaves, inconspicuous yellowish flowers before the leaves and small dark purple or black, berry-like fruits. *F. acuminata* is hardy in sheltered positions as far north as Massachusetts, while *F. ligustrina* is somewhat tenderer. They prefer moist soil and are suited for planting along streams. Propagation is by seeds and layers.

acuminàta, Poir. (*Adèlia acuminàta*, Michx.). Deciduous shrub, to 10 ft. high, sometimes spiny, glabrous: lvs. slender-petioled, ovate-oblong or ovate-lanceolate, remotely serrate, 1½–4 in. long: staminate fls. in dense clusters; pistillate fls. in short panicles: fr. narrow, oblong or cylindrical, deep purple, falcate, acute, ½in. long. W. Ill. to Texas. Michx. Fl. Bor. Amer. 2:225. B.B. (ed. 2) 2:728.

ligústrina, Poir. (*Adèlia ligústrina*, Michx.). Deciduous shrub, to 6 ft., pubescent: lvs. elliptic-obovate to oblong, obtuse, appressed-serrulate, about 1 in. long: fls. in fascicles: fr. sessile, ovoid, obtuse, ¼in. long. Tenn. to Fla. and Ala.

F. nèo-mexicàna, Gray (A. parvifolia, Coville). Shrub, to 10 ft.: lvs. spathulate, almost entire, usually glabrous, grayish green and rather small: fr. ovate or short-oblong, obtuse, ⅓in. Texas to New Mex. and Colo.
ALFRED REHDER.

FORESTRY is the rational treatment of forests; this treatment may vary with the object in view. Forests may subserve various objects, giving rise to three classes of forests: they furnish wood materials for the arts—*supply forests;* they furnish a soil cover, which may prevent the blowing of the soil and formation of sand-dunes, or may retard the erosion and washing of the soil and may regulate the waterflow, or act as a barrier to cold or hot winds, and exercise other beneficial influences on climate and surroundings—*protection forests;* or, finally, they furnish enjoyment to the esthetic and sporting elements in man, as game-preserves and parks—*luxury forests.* Any two or all three objects may be attained simultaneously in the same forest. In the end, and in a more limited sense, forestry is the art and business of making revenue from the growing of wood crops, just as all agriculture is finally concerned in producing values from food crops and other crops. In the economy of agriculture, wood crops may be grown on land that is too poor for field crops.

This art is divided into two distinct and more or less independent branches, namely silviculture, the technical branch, and forest management, the business branch. Silviculture is a branch of the larger subject arboriculture, and comprises all the knowledge and skill applied in producing the wood crop, relying mainly on natural sciences. While horticulture and silviculture have both to deal with trees, their object and with it their treatment of trees are totally different: the orchardist works for the fruit of the tree, the landscape gardener for the pleasing form; in both cases the object is attained by the existence of the tree and its single individual development; the forester is after the substance of the tree, the wood; his object is finally attained only by the removal of the tree itself. He deals with masses of trees rather than individuals: it is logs in quantity and of desirable quality, clear of knots, not trees, that he is working for; hence, his treatment differs from that of the horticulturist.

The clear long boles free of knots are secured by a dense stand, when by the shade of neighbors the lower branches are made to die and break off. When in this way clear boles to a certain height are secured, the stand is opened up by thinnings in order to secure expansion of crown and thereby more rapid increase in diameter of bole. There are several ways of reproducing the crop, namely artificially by sowing or planting, the latter being done with one- to four-year-old plants, at the rate of 1,500 to 4,000 to the acre; or by natural regeneration, either by sprouts from the stump, the so-called coppice, which is applicable to hardwoods and for the production of fuel wood and small-dimension material, or else by seed from mother or nurse trees. There are various procedures of securing a crop by seed, a so-called timber forest, which differ by the rapidity of the removal of the old crop or nurse trees, and by the size and progress of the opening—strip system, group system, selection system, and, the most refined, shelterwood system.

Since the crop takes many years to mature—sometimes a century and more—in order to carry on a continuous forestry business, from which to secure annual returns, special arrangements peculiar to this business must be made: these arrangements, naturally influenced by the economic conditions of the country, form the subject of forest organization or management.

The ideal of the forester to which he attempts a gradual approach with his actual unregulated forest is known as the "normal forest." It supposes that a rotation has been chosen, i.e. a year or period when the timber will be ripe (determined in various ways); that as many stands are at hand as there are years in the rotation, differing by one year from each other, so that each year a mature area can be harvested—a normal age-class gradation; that the increment on the whole area is the best attainable for species and site—a normal increment; that the amount of wood standing, the stock on which the increment is deposited, is the proper one for each age-class—a normal stock. This is the standard with which the actual forest is compared to judge its abnormalities, which by the management are to be, as far as practicable, removed.

Since the forest crop takes from thirty to one hundred years and more to mature, i.e., to produce desirable size, highest value, or best interest rate on the investment, it is a business which does not appeal to private enterprise: the long-time element, as well as the influence of forests on water-flow and other cultural conditions make forestry particularly a business to be conducted by the state or other long-lived corporation.

The horticulturist, as such, is mainly interested in the rational treatment of such forests as have a protective value, influencing climatic, soil and water conditions in general and locally.

The raising of trees for shade, for ornament, and for avenues is not forestry, but a branch of arboriculture (which see); the ornamental utilization of forests, as a part of grounds, is discussed under *Woods*.

B. E. Fernow.

1559. Flowers of Forsythia suspensa var. Fortunei. (×⅔)

FORGET-ME-NOT: *Myosotis.*

FORMAL GARDENING: *Landscape Gardening.*

FORSÝTHIA (after William Forsyth, prominent English horticulturist, director of the Royal Garden at Kensington, 1737–1804). *Oleàceæ.* Golden-Bell. Shrubs grown for their wealth of bright yellow flowers appearing early in spring, also for their handsome dark green foliage.

Deciduous: lvs. opposite, petioled, serrate or entire, simple or partly 3-parted to 3-foliolate: fls. 1–6, axillary, pedicelled, heterostylous; calyx and corolla deeply 4-lobed, lobes of the corolla oblong, longer than the campanulate tube; stamens 2, included, inserted at the base of the corolla; ovary superior; style slender with 2-lobed stigma: fr. a 2-celled, dehiscent caps. with many winged seeds.—Four species in China, Japan and S. E. Eu.

The golden-bells are highly ornamental, free-flowering shrubs, with simple or ternate leaves and showy yellow flowers, borne in great profusion along the slender branches in early spring before the leaves. They belong to the showiest early-flowering shrubs, and have handsome, clean foliage, remarkably free from insects or fungi, remaining unchanged until late in fall. The upright forms are well adapted for the borders of shrubberies and the pendulous form for covering walls, fences, arbors or porches. They grow in almost any kind of garden soil, and are hardy North except *F. viridissima*, which is somewhat tenderer. Propagation is readily by greenwood and hardwood cuttings; also by seeds. The branches of the pendulous form often take root at the tips when touching the ground, and send forth vigorous shoots, like some brambles or the walking-fern.

A. *Lvs. often 3-parted or 3-foliolate: branches hollow between the nodes (except in the hybrid).*

B. *Branches always hollow between the nodes: lvs. usually ovate, often 3-foliolate.*

suspénsa, Vahl. Shrub, to 8 ft., with slender branches often lopping on the ground and taking root: lvs. broad-ovate or oblong-ovate, serrate, 3–4 in. long: fls. 1–3, rarely to 6, about 1 in. long, golden yellow, tube striped orange-yellow within; calyx about as long as tube: caps. ovate, about 1 in. long. China. S.Z. 3. Gn. 73, p. 243. Var. **Fórtunei,** Rehd. (*F. Fórtunei,* Lindl.). Fig. 1559. Of upright habit with finally arching branches: lvs. often ternate, ovate or oblong-ovate: corolla with straight and spreading twisted segms. R.H. 1861:291. G. 4:79; 13:87. G.M. 50:227. F.E. 31:421. Var. **decípiens,** Koehne. A vigorous form of the preceding: fls. always solitary, on pedicels usually ½in., sometimes nearly 1 in. long, deep yellow, known only in the macrostylous form. Gt. 55, p. 203. Var. **pállida,** Koehne. Fls. always solitary, pale yellow. Var. **variegàta,** Butz. Lvs. variegated with golden yellow: fls. deep yellow. Var. **atrocaùlis,** Rehd. A form of var. *Fortunei* with dark purple branches and the young growth purplish. Cent. China. Var. **pubéscens,** Rehd. Similar to the preceding, but lvs. soft and short-pubescent on both sides or only below. Cent. China. Var. **Sièboldii,** Zabel (*F. Sièboldii,* Dipp.). Fig. 1560. Low shrub, with very slender, pendulous or trailing branches: lvs. mostly simple, broad-ovate or ovate: corolla-lobes flat and broad, slightly recurved. B.M. 4995. F.S. 12:1253. Gn. 33, p. 563. A.G. 13:94. G.F. 4:79. Gt. 55, p. 205.—*F. suspensa* is an excellent shrub for the margins of groups, because it finally rolls over and meets the greensward. It can also be trained over an arbor.

1560. Forsythia suspensa var. Sieboldii. (×½)

1561. Flowers of Forsythia viridissima. (×⅔)

BB. *Branches usually, particularly above, with lamellate pith between the nodes, pith at the nodes usually solid: lvs. only on vigorous shoots partly 2–3-parted or sometimes 3-foliolate, usually ovate-lanceolate.*

intermèdia, Zabel (*F. suspénsa* × *F. viridíssima*). Shrub, with slender, erect or arching branches: lvs. oblong to ovate-lanceolate, sometimes 3-lobed or ternate, usually coarsely serrate, 3–4 in. long: fls. almost like those of *F. suspensa* var. *Fortunei.* Gt. 1885:1182; 40, p. 397. Gn.W. 22:181. Var. **vitellìna,** Koehne (*F. vitellìna,* Koehne). With upright or spreading branches: fls. deep yellow, little over 1 in. long. Gt. 55, pp. 227, 228. Var. **spectábilis,** Spaeth (*F. spectábilis,* Koehne). Upright with spreading and somewhat arching branches: fls. somewhat paler than of the preceding, 1⅓ in. long, often 5–6-merous. Gt. 55, p. 229. G. 35: 255. Var. **densiflòra,** Koehne (*F. densiflòra,* Koehne). Upright shrub with divaricately spreading and slender arching branches: fls. crowded at the base of the branches, rather pale with flat slightly recurved corolla-lobes. Gt. 55, pp. 230, 231. Var. **primúlina,** Rehd. Upright shrub, with spreading and arching branches: fls. crowded at the base of the branches, pale yellow; lobes of the corolla revolute at the margin.—

F. intermedia is often confounded with forms of *F. suspensa*. In foliage it resembles much the following, which has the lvs. narrower, always simple, usually serrate only above the middle, with smaller teeth. It is as hardy as *F. suspensa* and very floriferous.

1562. Forsythia viridissima. (×½)

AA. *Lvs. always simple: branches, at least in their upper part, with lamellate pith throughout, including the nodes: habit upright.*

viridíssima, Lindl. Figs. 1561, 1562. Shrub, to 10 ft., with green, erect branches: lvs. oblong-lanceolate or lanceolate, always simple, and generally serrate only above the middle, very dark green, 3–6 in. long: fls. 1–3, about 1 in. long; corolla with rather narrow, twisted lobes of bright, somewhat greenish yellow; calyx about half as long as tube. China. B.M. 4587. F.S. 3:261. B.R. 33:39. H.F. 1852: 97. J.H. III. 65:423. Gn. 33, p. 563. G. 2:65; 28:39. A.G. 13:94. Var **variegàta**, Hort. Lvs. variegated with white.—Less hardy and graceful than the preceding forms.

europǽa, Degen & Baldacci. Upright shrub to 6 ft.: lvs. usually ovate to ovate-lanceolate, entire or at the end of vigorous shoots with shallow teeth, 2–3 in. long: fls. 1–3, about 1 in. long, short-pedicelled, golden yellow; calyx-lobes ovate-ciliate, shorter than the corolla-tube: caps. ovoid, about ½in. long. Albania. B.M. 8039. Gt. 54, p. 291. G.C. III. 36:123. J.H.S. 29: 663. F.E. 18:348.

F. Giraldiàna, Lingelsh. Upright shrub: lvs. elliptic to oblong, long-acuminate, broadly cuneate at the base, entire or serrulate, glabrous or hairy on the veins beneath, 2–5 in. long: fls. short-stalked: caps. ovoid with a long and slender beak. N. W. China.

ALFRED REHDER.

FORTUNEÀRIA (after Robert Fortune, who traveled during the years 1843–61 in China and Japan and introduced a large number of highly ornamental plants). *Hamamelidàceæ.* Ornamental shrub, grown for its handsome foliage.

Stellate-pubescent: lvs. deciduous, alternate, serrate, with small caducous stipules: fls. small, short-pedicelled, in terminal racemes; calyx turbinate with 5 short lobes; petals 5, subulate, slightly shorter than sepals; stamens 5, with short filaments; ovary partly superior with 2 filiform revolute styles: fr. a dehiscent woody caps., separating into 2 valves bifid at the apex; seeds glossy, dark brown; embryo with large cotyledons revolute at the margin.—One species in Cent. China. Very similar in habit and foliage to Sinowilsonia, but the fls. and the embryo are very different. In general appearance it suggests the hazel; fls. and frs. insignificant. Has proved hardy at the Arnold Arboretum. Prop. is by seeds and possibly by grafting on Hamamelis.

sinénsis, Rehd. & Wilson. Shrub to 6 ft.: lvs. obovate or obovate-oblong, short-acuminate, usually rounded at the base, sinuate-denticulate, glabrous above, pubescent on the veins below, 3–5½ in. long: fls. scarcely ⅛in. across in racemes about 2 in. long: caps. ovoid, less than ½in. long. May. Cent. China.

ALFRED REHDER.

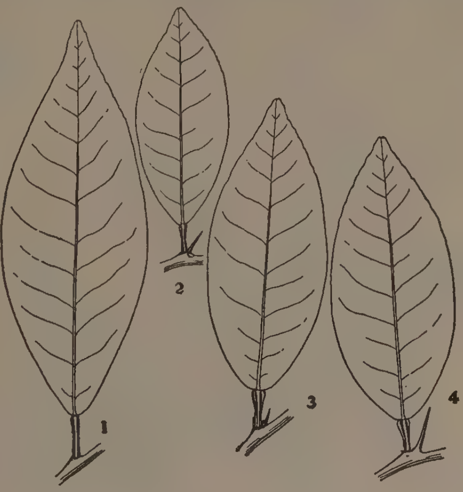
FORTUNÉLLA (named for Robert Fortune, who in 1846 introduced the first kumquat into Europe). *Rutàceæ*, tribe *Cítreæ.* KUMQUAT. Evergreen shrubs, grown for their small ornamental fruits, which are also preserved and eaten fresh. See *Kumquat.*

Leaves unifoliate, thick, pale and densely glandular-dotted below: stamens 4 times as many as the petals, polyadelphous; ovary 3–6- (rarely 7-) celled, ovules 2 in each cell; stigma cavernous: frs. like Citrus but smaller, 1–1½ in. diam., globose or oval, skin usually thick, sweet and edible; seeds green in section, cotyledons hypogeous in germination: first foliage-lvs. broadly ovate, opposite. Differs from Citrus in having a few-celled ovary with only 2 ovules in a cell, and a cavernous stigma; from Atalantia in having 4 times as many stamens as petals.—Four species are recognized.

The two commonly cultivated species of kumquats have been referred by botanists to Citrus, but the obviously related Hongkong wild kumquat has been referred to Atalantia. The kumquats are, as a matter of fact, out of place either in Citrus or Atalantia and constitute a separate genus about midway between these two. See Journ. Wash. Acad. Sci. 5:165–176 (No. 5, March 4) 1915.

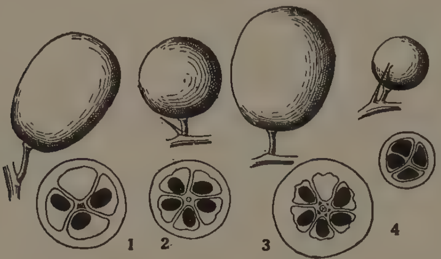
A. *Subgenus Eufortunella. Fr. 4-, 5-, 6- (or rarely 7-) celled, pulp vesicles abundant, their stalks arising from the smooth ovary wall, peel of fr. thick and fleshy. The kumquats proper.*

margarìta, Swingle (*Cítrus margarìta*, Lour.). Figs. 1563, 1564. OVAL KUMQUAT. NAGAMI KUMQUAT. A shrub or small tree, thornless or nearly so: twigs slender, angled when young, often somewhat tufted: lvs. lanceolate, tapering toward both ends, the tip abruptly rounded, sometimes emarginate, the base cuneate, margin usually obscurely crenate above the middle, dark green above, veins scarcely visible, pale green and densely glandular-punctate below: fls. arising singly or in few-fld. clusters in the axils of the lvs., small, ⅖–⅗in. diam.; pedicel short, 1½–2½ lines long; bud more or less angular in cross section; pistil short, 2–2½ lines; style persistent, scarcely longer than the ovary; stigma capitate, cavernous, with large, deep-seated oil-glands between the stylar canals; ovary 4- or 5-celled, ovules 2 in a cell, usually collateral: frs. oval or oblong, 1–1⅕ x ⅝–1 in., rarely 1⅓–1½ in. long, yellowish orange with large translucent oil-glands imbedded in the thick and fleshy skin; pulp-vesicles abundant, fusiform, pulp acid; seeds large, 5–6 x 3–3½ x 2–2½ lines, oval; embryos one or several, pistache-green in section; germination with hypogeous cotyledons: first foliage-lvs. opposite,



1563. Leaves of Fortunella. (×½) 1, F. margarita; 2, F. japonica; 3, F. crassifolia; 4, F. Hindsii.

oval, narrowed at the base but without a sharply delimited jointed petiole B.M. 6128. G.C. II. 2:336. Hume, Citr. Fr. p. 129.— The oval kumquat, the type of the genus Fortunella, is the most vigorous member of the genus, the branched shrub or tree attaining a height of 10–12 ft. and the lvs. sometimes reaching 6 in. length and 2 in. width. It was the first kumquat to reach Eu., having been brought to England by Robert Fortune in 1846. Because of its superior vigor it is the one most commonly grown commercially, but the frs. are inferior to those of the following species, the skin being harsh in flavor because of the biting quality of the oil.



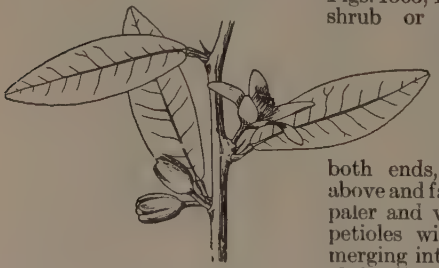
1564. Fruits with cross-sections of Fortunella. (X½) **1, F. margarita; 2, F. japonica; 3, F. crassifolia; 4, F. Hindsii.**

japónica, Swingle (*Cítrus japónica,* Thunb.). Round Kumquat. Marumi Kumquat. Figs. 1563–1565. A much-branched shrub with very short spines or none: differs from *F. margarita* in the broader and blunter pointed smaller lvs., 1⅗–4 x ⅗–1⅖ in., paler and veinless below, round frs. ⅝–1⅕in. diam., not showing any persistent rudiment of the style, and usually with 5–6 segms.: seeds small, 3½–5 x 3–3½ x 2–2½ lines, oval, blunt-pointed, the empty testa not projecting beyond the end of the embryo. Ill. Rumph. Herb. Amb. 1:110, pl. 31. Thunb. Icon. Pl. jap. 2, pl. 5. Hume, Citr. Fr. p. 129.—The round kumquat is perhaps the most handsome of the citrous frs. because of its dwarf habit, much-branched twigs, and small, bright orange-colored frs.

crassifòlia, Swingle. Meiwa Kumquat. Figs. 1563, 1564. A much-branched shrub with very short spines or none: differs from *F. margarita* in the more rounded frs. 1–1½ x 1–1⅛ in., with 6 or 7 cells, not 4 or 5, and in the thicker trough-shaped lvs. sometimes more abruptly pointed toward the tip, and paler green below: petioles narrowly winged, not merely margined. It differs from *F. japonica* in the lf. characters and the slightly oval frs. with 6 or 7 cells and a thicker peel. It differs from both species in having much broader oval or ovate pulp-vesicles.—This kumquat recently intro. into the U.S. by Japanese nurserymen is as yet but little known.

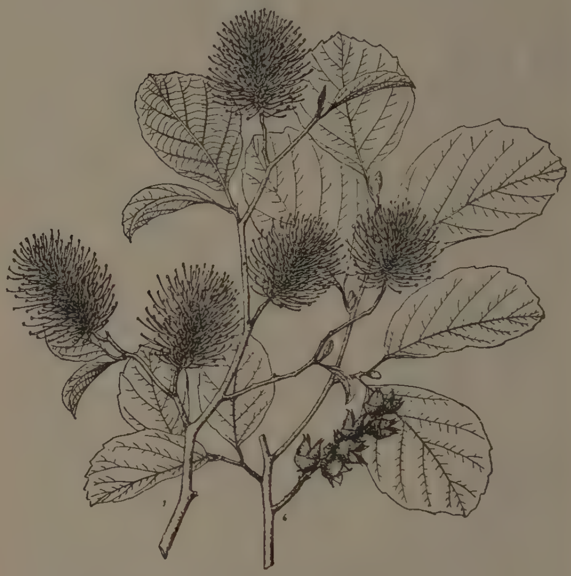
AA. *Subgenus Protocitrus. Fr. 3–4-celled, having between the stalks of the pulp-vesicles many minute wart-like, pale yellow cellular masses, peel of fr. thin and but slightly fleshy. The Hongkong wild kumquat.*

Hìndsii, Swingle (*Sclerostỳlis Hìndsii,* Champ. *Atalántia Hìndsii,* Oliver). Hongkong Wild Kumquat. Figs. 1563, 1564. A spiny shrub or small tree: twigs slender, angled when young: lvs. oval-elliptical, tapering sharply at both ends, dark green above and faintly venose, paler and venose below, petioles winged, often merging into the lamina of the lf. without a separative joint: fls. short, broad; pistil very short; style shorter than the ovary, stigma large, cavernous; ovary 3- or 4-celled, ovules 2 in a cell: frs. small, ⅗–⅘in. subglobose, bright orange-red; pulp-vesicles very few, small, fusiform; seeds thick, oval or ovate, plump, 4½–5½ x 3½–4 x 2½–3 lines, pistache-green in section. Ill. Seeman, Bot. Voy. H. M. S. Herald, 1852–1857, pl. 82.—The Hongkong wild kumquat grows commonly on the dry hills about Hongkong and on the mainland of China opposite. It is the most primitive of the true citrous frs. and doubtless the species of Citrus have evolved from such a plant.



1565. Buds and flower of Fortunella japonica.

Walter T. Swingle.



1566. Fothergilla.—Leaves of F. Gardenii and flowers of F. major. (X½)

FOTHERGÍLLA (after John Fothergill, eminent English physician, who introduced and cultivated many new plants, 1712–1780). *Hamamelidàceæ.* Dwarf Alder. Shrubs, chiefly grown for their showy spikes of white flowers and also for the handsome foliage.

Deciduous, more or less stellate-pubescent: lvs. alternate, short-petioled, coarsely toothed, stipulate: fls. in terminal spikes, perfect, apetalous; calyx campanulate, 5–7-lobed; stamens numerous, with the filaments thickened toward the end: caps. dehiscent, 2-celled and 2-seeded.—Four species in the southern Atlantic states.

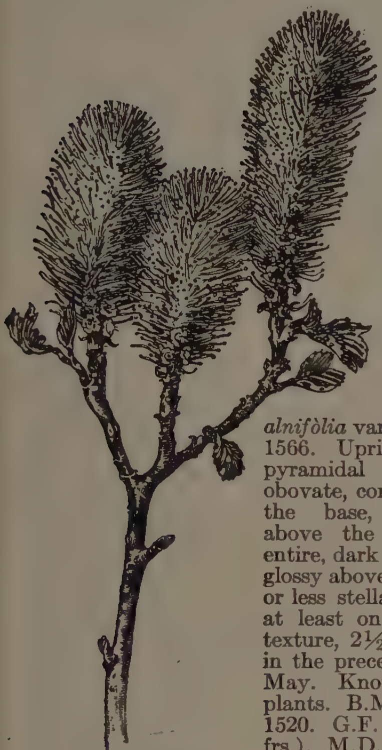
These are hardy ornamental shrubs with simple, dull green leaves, and showy spikes of white flowers in spring with the leaves: the distinct foliage resembles somewhat that of the alder, or more that of Hamamelis, and turns yellow late in fall. They grow best in moist, peaty or sandy soil. Propagation is by seeds, not germinating until the second year, or by layers, which take two years to root; the first species also by suckers and root-cuttings.

A. *Lvs. rarely exceeding 1 in., stellate-pubescent above: low shrub.*

Gárdenii, Murr. (*F. alnifòlia,* Linn. f. *F. carolìna,* Brit.). Fig. 1566. Low shrub, with generally spreading branches, to 3 ft.: lvs. oblong or obovate, rounded or cuneate at the base, coarsely dentate above the middle, pubescent above, pale or glaucous and tomentose below, 1–2 in. long: spikes ovate or oblong, 1–2 in. long, leafless at the base; stamens ⅓in. long, sometimes pinkish. April, May. Va. to Ga. B.M. 1341. L.B.C. 16:1507.

AA. *Lvs. 2–5 in. long, glabrous or glabrescent above: shrubs to 10 ft. high.*

montícola, Ashe. Fig. 1567. Upright shrub with spreading branches: lvs. roundish oval to broadly obovate or obovate, remotely dentate, often from below the middle, light green and sparingly pubescent below, often only on the veins, 2–4 in. long: spikes 1½–3 in. long with 1–3 lvs. at the base; stamens ½in. long: caps. ½in. long. April, May. N. C. to Ala.—Has proved hardy at the Arnold Arboretum, like the preceding and the following species.



1567. Fothergilla monticola. (×⅔)

màjor, Lodd. (*F. alnifòlia* var. *màjor*, Sims). Fig. 1566. Upright shrub of dense pyramidal habit: lvs. oval or obovate, cordate or truncate at the base, sinuately dentate above the middle or nearly entire, dark green and somewhat glossy above, glaucous and more or less stellate-pubescent below, at least on the veins, of firm texture, 2½–5 in. long: fls. like in the preceding species. April, May. Known only from cult. plants. B.M. 1342. L.B.C. 16: 1520. G.F. 8:445 (excl. lvs. and frs.). M.D.G. 1902:395, 396.—This species is superior to the former on account of its dense, pyramidal habit.

F. parviflòra, Kearney. Closely related to F. Gardenii. Lower and stoloniferous: lvs. nearly orbicular, rounded or cordate at the base, toothed from below the middle. N. C. to Fla.

Alfred Rehder.

FOUQUIÈRIA (Pierre Ed. Fouquier, professor of medicine at Paris in the first part of the nineteenth century). *Fouquieriàceæ.* Candlewood. Four species from the deserts of Mexico and one extending into the United States and sometimes cultivated in the larger rockeries of California. These plants are interesting as being an example of an order far removed from the Cactaceæ in flowers and fruit but reduced to something of their habit by the desert conditions.

Small trees or shrubs, becoming leafless in dry weather, with showy tubular fls. in terminal racemes or panicles: lvs. fleshy, obovate, fascicled in the axils of thorns: sepals 5; corolla with a spreading 5-lobed limb; stamens 10–∞; styles 3, separate or united: seeds with a membranous wing or fringed with long hairs. Fouquieria is by some authors retained in the Tamaricaceæ.

splêndens, Engelm. Coach-whip. Vine-Cactus. Jacob's Staff. Ocotillo. Shrub, 6–25 ft., branching near the base: branches long, gray, furrowed, erect: lvs. obovate, rounded at apex, wedge-shaped at base, ½–1 in. long: fls. scarlet or brick-red, exceeding 1 in. long, in racemose or thyrsoid elongated clusters; stamens 8–12, exserted: caps. ½–⅔in. long, the seeds white, with a long fringe of spirally thickened hairs. W. Texas and Ariz. to S. Calif. B.M. 8318. A.G. 13:759.—A hedge plant in Mex., making an impentrable barrier. The plant is a conspicuous object in the deserts from Texas westward, standing on the open exposed places and slopes, the rod-like stiff canes looking like lifeless sticks in dry weather and in its season crowned with masses of showy bloom.

L. H. B.†

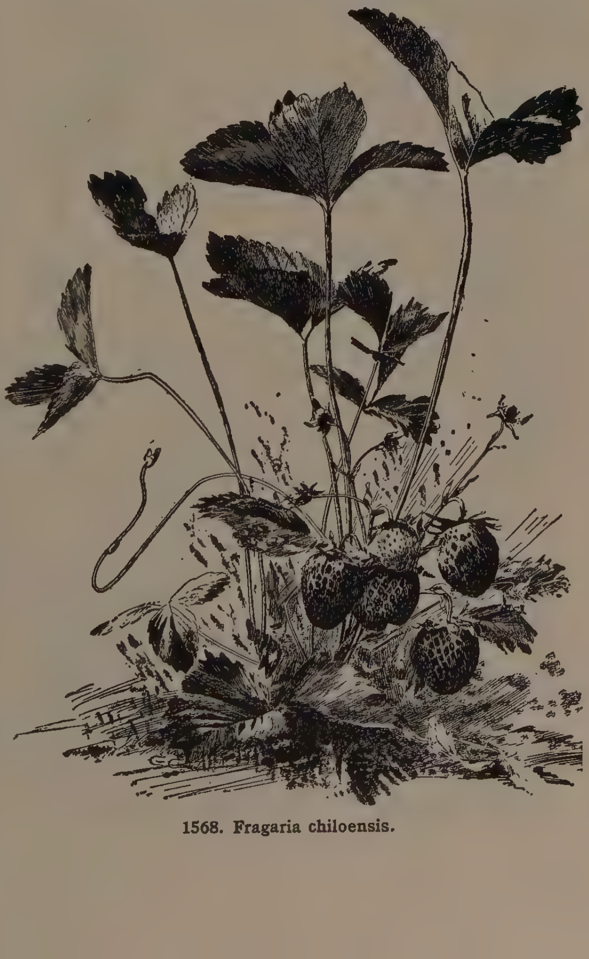
FOURCRÒYA: *Furcræa.*

FOUR-O'CLOCK: *Mirabilis Jalapa.*

FOXGLOVE: *Digitalis.*

FRAGÀRIA (Latin, fragrance, from the smell of the fruit). *Rosàceæ.* Strawberry. Low perennial creeping herbs grown for the excellent fruit, and one or two species for ornament.

Plant stemless, with scaly rootstock or crown, and rooting runners: lvs. palmately 3-foliolate and toothed, all from the crown: fls. white or reddish, in corymbose racemes on slender, leafless scapes, sometimes lacking stamens; calyx deeply 5-lobed and reinforced by 5 sepal-like bracts; petals 5, obovate, elliptic or orbicular; stamens many, short; pistils many, on a conical receptacle, becoming small and hard achenes and persisting on the enlarging receptacle, which becomes pulpy and edible.—The fragarias are exceedingly variable. About 150 specific names have been applied to them, but Bentham and Hooker would reduce them all to 3 or 4 species, and Focke (in Engler & Prantl) to about 8. Rydberg, however, accepts 27 N. American species (N. Amer. Flora, XXII, part 4. 1908). Of the true fragarias, about 4 species-types are interesting to the horticulturist as the parents of the garden strawberries:—*F. chiloensis*, the probable original of the ordinary cultivated strawberries of Amer.; *F. virginiana*, which was early domesticated, and of which some trace still remains in cult. varieties; *F. moschata*, the Hautbois, and *F. vesca*, the alpine and perpetual strawberries, which are little cult. in this country. The classical work on straw-



1568. Fragaria chiloensis.

1569. Fragaria virginiana, showing the profuse runners.

berries is Duchesne's "Histoire Naturelle des Fraisiers," 1766. See *Strawberry*. For *Fragaria indica*, see *Duchesnea*.

A. *Lfts. distinctly petiolulate, few-toothed.*

Daltoniàna, Gay (*F. sikkiménsis*, Kurz). Small plant with red sts. to the very slender runners, offered as a rock-garden subject or carpeter: hairy or nearly glabrous: fls. solitary; calyx-lobes and bracts toothed: fr. long (1 in. long by half as broad), bright scarlet, with little flavor. Himalayas, 10,000 ft. and upward.

AA. *Lfts. sessile or nearly so, many-toothed.*

B. *Lvs. normally overtopping the fls. and fr.: achenes mostly sunken in the flesh of the berry.*

chiloénsis, Duchesne. Fig. 1568. Low, but stout in all its parts: lvs. thick, more or less glossy above, bluish white below, blunt-toothed: fl.-clusters forking and long-rayed, the peduncle short, soon lopping on the ground: runners mostly appearing after the fr. is gone: berry large and firm, dark-colored, more or less musky in flavor, reinforced by a very large calyx or hull. Pacific coast region Peru to Patagonia. —A common wild strawberry of the Pacific slope from Alaska to Calif., is considered to be the same species.

Var. **ananássa**, Hort. (*F. ananássa, F. tíncta, F. calyculàta*, Duchesne. *F. grandiflòra*, Ehrh. *F. vésca* var. *anànas*, Ait.). Pine Strawberry. Common Garden Strawberry. Taller growing: lvs. larger and thinner, mostly lighter green on both sides: fr. larger, running into very many kinds.

virginiàna, Duchesne. Scarlet or Virginian Strawberry. Figs. 1569, 1570. More slender: lvs. thinner, light green above and below, the upper surface with sunken veins: fl.-clusters small, with a few hanging frs. at the top of a rather long peduncle: runners usually appearing with the fr.: berry small, light scarlet, globular or oblong-conical, usually with a constriction or neck underneath the moderate-sized calyx or hull. E. N. Amer.—Variable. A few early varieties of strawberries, as Crystal City, seem to be wholly or partly of *F. virginiana* origin. Var. **illinoénsis**, Gray (*F. illinoénsis*, Prince. *F. Grayàna*, Vilm. *F. virginiàna* var. *Grayàna*, Rydb.). A large and more robust form, more hairy, the hairs on the pedicels spreading whereas on the type they are more appressed.

BB. *Lvs. normally shorter than the fl.-clusters: achenes usually not sunken in the flesh of the berry.*

1570. Fruit of Fragaria virginiana. (Nat. size)

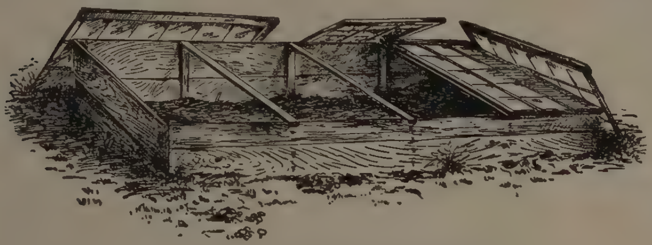
vésca, Linn. (*F. semperflòrens*, Duchesne). Alpine and Perpetual Strawberries. Erect and dark green, only sparsely hairy, the lvs. thin and light green as compared with the foregoing species, very sharp-toothed: fl.-cluster small, forking, erect: fr. firm, small, usually hemispheric, the achenes very prominent; hull spreading. Eu.—The American more slender form of this group-species, common in woods from Va. north, is var. **americàna**, Porter (*E. americàna*, Brit.), Fig. 1571, with ovoid or somewhat conical fr. usually with a distinct neck, and sparingly hairy rather than hairy-pubescent petioles and scapes, and thinner lvs. The true *F. vesca* is thought to be sparingly naturalized eastward, and probably native in many parts, particularly the white-fruited form (forma *albicárpa*, Brit.). The cult. forms are rarely seen in this country, but the quality is high, and they are deserving of more attention in home grounds. Variable in cult. There is a form with lfts. reduced to 1 (*F. monophýlla*, Duchesne. B.M. 63). This type of strawberry bears more continuously than *F. chiloensis* and *F. virginiana* in its cultivated forms.

1571. Fragaria vesca var. americana. (Separate fruit nat. size)

moschàta, Duchesne (*F. elàtior*, Ehrh.). HAUTBOIS. Taller, usually diœcious, more pubescent, the calyx or hull strongly reflexed from the fr.: berry dull red, musky. Eu.—Cult. forms rarely seen in Amer.

mexicàna, Schlecht. Lvs. few and scape solitary: lvs. rather thin, soon becoming smooth above, the slender silky petioles 2–3 in. long; lfts. oblong-obovate or cuneate, coarsely serrate: fls. usually less than ½in. diam., on scapes 2–4 in. high; sepals and bracts silky; petals obovate: fr. nearly hemispheric, small, the achenes superficial. Cent. Mex.—The "everbearing strawberry," frequently advertised, is said to belong here. *F. califórnica*, Cham. & Schlecht., is similar but has much longer petioles and broadly rounded or rhomb-ovate lfts., somewhat larger fls. and fr., and the achenes in shallow pits. Calif., New Mex., Lower Calif.

L. H. B.



1572. A frame.—It accommodates four sashes.

FRAGRANT BALM: *Monarda didyma.*

FRAME. Fig. 1572. A box without permanent top or bottom which is designed, when covered with glass or other transparent material, as a place in which to grow plants. When supplied with artificial bottom heat, the frame is part of a hotbed; when supplied only with sun heat, it is part of a coldframe. The frame may be of any size, but the normal size is 6 by 12 feet, an area which accommodates four 3- by 6-foot sashes; and this 6 by 12 area is understood when one speaks of "a frame." See *Hotbed.*

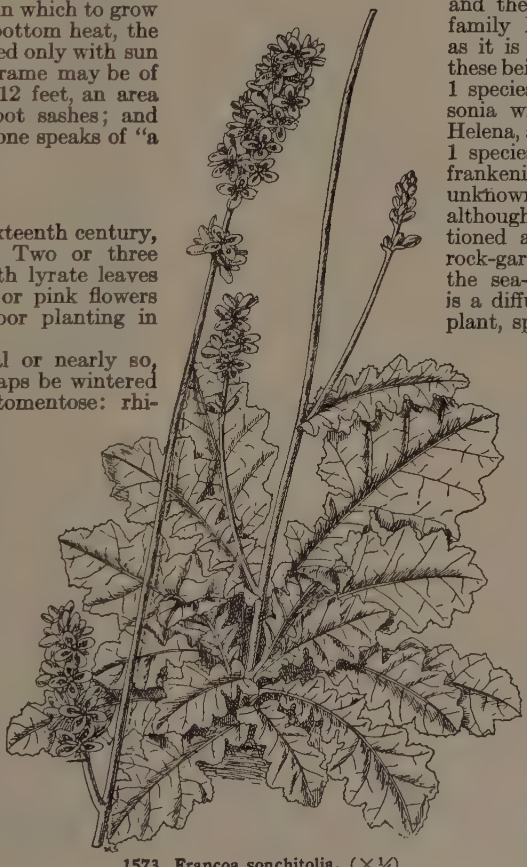
FRANCÍSCEA: *Brunfelsia.*

FRANCÒA (Fr. Franco, Valencia, sixteenth century, promotor of botany). *Saxifragàceæ.* Two or three species of Chilean perennial herbs, with lyrate leaves and terminal dense racemes of white or pink flowers borne in summer, suitable for outdoor planting in mild climates.

Plants erect, scapose, the lvs. basal or nearly so, 2–3 ft. high, and in the N. could perhaps be wintered in a coldframe: glandular-pilose or tomentose: rhizome thick, many-headed: lvs. glandular-dentate: fls. 1 in. across, in racemes 6 in. long; floral parts in 4's rarely 5's; petals obovate, clawed; stamens 4: caps. coriaceous, elongated, 4-angled and 4-celled.

A. *Fls. white.*

ramòsa, D. Don. (*F. glabràta*, DC.). Taller, woodier and more branching than the others, and distinguished by pubescent infl.: lf.-stalks not margined: fls. smaller. Hardy at Washington, D. C., with spikes 2 ft. long and 1 in. thick. Forms are known under the names *F. ramosa hybrida* (G.W. 7:230, a robust plant with pure white fls. larger than the type); and *F. ramosa candida. F. ramosa* is an attractive species. Gt. 60:1590. Gn. 69, pp. 271, 343; 70, p. 283. G.L. 24:177. G. 7: 741; 13:307. G.M. 49:127.



1573. Francoa sonchifolia. (×¼)

AA. *Fls. mostly pink.*

sonchifòlia, Cav. Fig. 1573. Lf.-stalks broadly winged at the base; lower lobes continuous with the broad margin at the base of the lf.-stalk: petals deep rose, dark-spotted. B.M. 3309.—By some considered to be a variety of *F. appendiculata.*

appendiculàta, Cav. Lf.-stalks not winged at the base; lower lobes distant from the base of the stalk: petals pale rose, rarely spotted. B.M. 3178 (shows a white longitudinal band on petals). B.R. 1645. L.B.C. 19:1864, erroneously named *F. sonchifolia.* R.H. 1906, pp. 428, 429. G.W. 12, p. 260.

L. H. B.†

FRANGIPANI: *Plumeria.*

FRANKÈNIA (John Frankenius, Swedish botanist, 1590–1661). *Frankeniàceæ.* Low perennials, evergreen, sometimes woody, mostly in saline soils, more or less heath-like: lvs. opposite or in 4's, thickish, entire, small and numerous on the sts., often fascicled on short branchlets: fls. small, perfect and complete, sessile or nearly so, solitary or in dichotomous clusters; calyx and corolla 4–5-merous, the sepals united, the petals with a crown at the base of the blade; stamens usually same number as petals and alternate with them; style 3–4-cleft; ovary 1-celled, with parietal placentæ, ripening into a caps. inclosed in the calyx.—Probably 30 species in many parts of the world, a very few of them in the S. W. U. S. The family Frankeniaceæ is closly allied to Caryophyllaceæ, from which it differs in the parietal placentæ, and to Hypericaceæ, from which it differs in habit, in the definite stamens and the valvate calyx. The family has 3 other genera, as it is defined by Niedenzu, these being Hypericopsis with 1 species in S. Persia, Beatsonia with 1 species in St. Helena, and Niederleinia with 1 species in Patagonia. The frankenias are practically unknown as cult. plants, although sometimes mentioned as carpeters and for rock-gardens. *F. lævis*, Linn., the sea-heath, is offered. It is a diffusely much-branched plant, spreading 6–8 in., glabrous or nearly so: lvs. revolute and thereby appearing linear, crowded in opposite clusters: fls. few, sessile in terminal leafy clusters, pink. England and the Medit. region. *F. pulverulénta*, Linn., is a closely allied hairy species; it has been reported in ballast at New York.

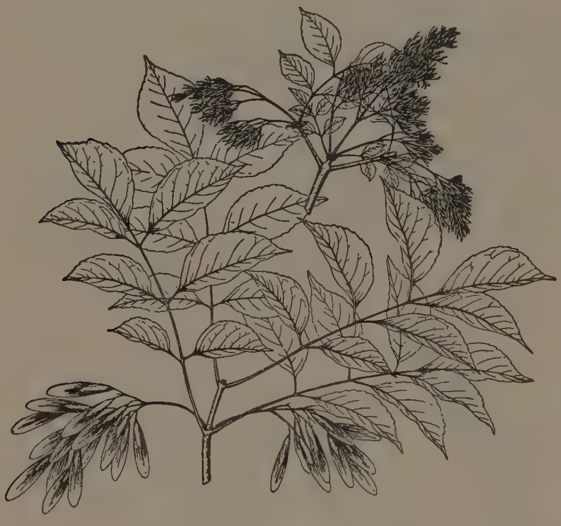
L. H. B.

FRASÈRA (John Fraser, English botanist, collected in Amer. 1785–96 and published Walter's "Flora Caroliniana"). *Gentianàceæ.* COLUMBO.

Large stout glabrous herbs, all N. American, and all but 1 far-western with a single st. from thick bitter mostly biennial roots, opposite or whorled lvs., and cymose panicled clusters of dull white, yellowish or bluish fls. which are commonly dark-spotted; calyx deeply 4-parted; corolla wheel-shaped, 4-parted, persistent, the lobes glandular within; stamens 4, the filaments often united at the base; ovary 1-celled, the stigma entire or 2-lobed.—Species 8, mostly in woods or dry soils. Three of the species have been offered in the trade, but are probably very little planted. *F. carolinénsis*, Walt., of the eastern states and Ont., is a biennial or short-lived perennial, 3–4 ft. tall, with lance-oblong or spatulate veiny lvs. mostly in 4's, and greenish yellow purple-dotted fls.

A. *Lvs. in whorls of 4–6, not white-margined.*

speciòsa, Douglas. Stout, 2–5 ft., very leafy, the lvs. ovate to oblong: fls. greenish white or barely tinged bluish, dark-dotted; 2 glands on each corolla-lobe. Wyo., S. and W.



1574. Fraxinus Bungeana. (×⅓)

AA. *Lvs. in 2's or 3's, white-margined.*

Párryi, Torr. Height 2–3 ft.: lvs. opposite or in 3's: fls. whitish, dark-dotted; 1 notched gland on each corolla-lobe. Ariz., S. Calif.

Cùsickii, Gray. Slender, height 3–8 in.: lvs. opposite: fls. bluish; 1 gland reaching from near the base to near the middle of each corolla-lobe. Ore.

L. H. B.†

FRAXINÉLLA: *Dictamnus.*

FRÁXINUS (ancient Latin name). *Oleàceæ.* Ash. Interesting trees grown chiefly for their handsome pinnate leaves and some species also for the conspicuous panicles of white flowers.

Deciduous: lvs. opposite, odd-pinnate, without stipules: fls. in panicles, diœcious or polygamous, with or without calyx or with calyx and a 2–6-parted corolla with generally linear segms.; stamens generally 2; ovary 2-celled: fr. a 1-seeded, winged samara.—About 50 species in the temperate regions of the northern hemisphere south to Cuba; 16 of them occur in the U. S.

The ashes are ornamental trees, most of them hardy, with rather large leaves and small flowers in panicles, either appearing before the leaves and greenish, or in the subgenus Ornus after or with leaves and whitish in showy panicles: the winged fruit is insignificant. They are valuable as street and park trees, and grow mostly into tall, pyramidal or broad-headed trees, with rather light green foliage, which turns yellow or dark purple in fall or remains green, as in *F. excelsior* and *F. Ornus.* The ash is seldom severely injured, though a number of insects and fungi prey on the leaves and wood, of which two borers, and a fungus attacking the leaves are perhaps the most obnoxious. Most of the species are hardy North except those from the southern states, southern Europe and Himalayas; of the subgenus Ornus, *F. Bungeana* and *F. longicuspis* seem to be the hardiest. The ashes are important forest trees, and the straight-grained and tough wood is much used for handles of tools, in the manufacture of carriages and wagons, for the interior finish of houses, and for furniture, for baskets and also for fuel. From *F. Ornus* manna is obtained as an exudation of the trunk, and some Chinese species, especially *F. chinensis* and *F. Mariesii*, yield the Chinese white wax.

The ashes grow in almost any moderately moist soil, *F. nigra* being somewhat more moisture-loving, while *F. oxycarpa*, *F. Ornus*, *F. syriaca* and *F. cuspidata* grow well even in drier situations. They are usually readily transplanted and grow rapidly when young. Propagation is by seeds gathered in fall and sown immediately, or stratified and sown in spring, covered with about 1 inch of good soil; sometimes they remain dormant until the second year. The varieties and rarer kinds are budded in late summer or grafted in spring on the seedlings of any of the common species.

A. *Fls. in terminal panicles on leafy shoots, perfect or polygamous, with or after the lvs. (Ornus.)*

B. *Corolla present, divided nearly to the base; stamens with long filaments.*

C. *Petioles not conspicuously enlarged at the base.*

D. *Lowest pair of lfts. not much smaller than the others.*

E. *Lfts. stalked.*

1. **Órnus,** Linn. (*Órnus europæa*, Pers. *F. floribúnda*, Hort., not Wall.). Small tree, becoming 25 ft.: winter-buds gray or brownish tomentulose: lfts. generally 7, stalked, oblong-ovate or ovate, irregularly serrate, rufously pubescent on the midrib beneath, 2–3½ in. long: fls. whitish, fragrant, in dense, terminal panicles 3–5 in. long: fr. erect, narrow-oblong, truncate or emarginate at the apex, about 1 in. long. May, June. S. Eu., W. Asia. Gn. 22, p. 117; 34, p. 78; 48, p. 286; 31, pp. 354, 355. F.E. 22:61. G. 18:541. G.M. 54:860. H.W. 3:60, p. 120. Var. **juglandifòlia,** Tenore (var. *latifòlia*, Dipp. *F. rotundifòlia*, Hort.). Lfts. ovate or broadly ovate-oblong. Var. **rotundifòlia,** Tenore (*F. rotundifòlia*, Lam.). Low tree: lfts. roundish-elliptic to roundish-obovate. Var. **angustifòlia,** Tenore (*F. Theophrástii*, Hort., partly). Lfts. lanceolate.

2. **Bungeàna,** DC. (*F. parvifòlia,* Lingelsh. *F. Bungeàna* var. *parvifòlia,* Wenzig). Fig. 1574. Small tree, to 15 ft., or shrub: winter-buds nearly black: lfts. generally 5, stalked, ovate, obovate or roundish, obtuse to short-acuminate, serrate, glabrous, 1–1½ in. long: panicles to 2½ in. long, many-fld.; calyx with narrow acute lobes; filaments longer than the linear petals: fr. narrow-oblong, obtuse or emarginate. May. China. G.F. 7:5 (adapted in Fig. 1574).

EE. *Lfts. sessile.*

3. **obovàta,** Blume (*F. Bungeàna* var. *obovàta,* Lingelsh.). Tree: petioles often slightly winged; lfts. 5–7, oval or obovate, short-acuminate to obtusish, cuneate at the base, crenate-serrate, dull green above and slightly pubescent on the veins, grayish green below and pubescent toward the base of the veins, 2–4 in long: infl. small; petals linear, longer than the stamens: fr. with narrow-oblong obtuse wing. Japan.

DD. *Lowest pair of lfts much smaller than the others; lfts. long-acuminate.*

4. **longicúspis,** Sieb. & Zucc. Slender tree, to 30 ft., with rufously pubescent winter-buds: lfts. 5–7, stalked, oblong-lanceolate, long-acuminate, obtusely serrate, almost glabrous, 2–4 in. long: fls. in rather slender, narrow panicles, to 4 in. long; petals linear-oblong, about as long as stamens: fr. oblanceolate, obtuse. May. Japan. S.I.F. 1:81. Var. **Sieboldiàna,** Lingelsh. (*F. Sieboldiàna,* Blume). Lfts. oval to oblong-ovate, short-stalked, usually pubescent below along the midrib. Japan, Korea. Var. **sambúcina,** Lingelsh. (*F. Sieboldiàna* var. *sambúcina,* Blume). Lfts. sessile.

5. **Mariésii,** Hook. f. Shrub or small tree: winter-buds grayish black: petiole minutely glandular-pubescent; lfts. 5–7, nearly sessile, close, touching each other, ovate to ovate-lanceolate, acute or acuminate, entire or finely crenate-serrate, yellowish green below and glandular-puberulous on the midrib toward the base, otherwise glabrous, 1½–3 in. long: panicle upright, 5 in. long; petals linear-spatulate about as long as stamens. Cent. China. B.M. 6678.—Handsome and free-flowering; blooms even as a small shrub.

CC. *Petioles distinctly enlarged at the base: lfts. sessile, the lowest pair smaller.*

6. **Spaethiàna,** Lingelsh. (*F. serratifòlia,* Hort., partly). Tree: young branchlets glabrous: winter-buds dark brown: lvs. 6–12 in. long; petiole grooved, reddish brown at the enlarged base, glabrous; lfts. 5–9, oblong to oblong-obovate, deeply crenate-serrate, dark green above, lighter green below and glabrous except along the midrib toward the base, 3–7 in. long: fls. and frs. unknown. Origin unknown.—Handsome tree with large lvs.

BB. *Corolla with a short tube or wanting.*

C. *The corolla with short tube; anthers almost sessile.*

7. **cuspidàta,** Torr. Shrub or small tree, to 20 ft., with dark, reddish brown buds: lfts. usually 7, slender-stalked, lanceolate or oblong-lanceolate, acuminate, coarsely serrate, almost glabrous, 1½–2 in. long: fls. fragrant, in 3–4-in. long panicles: fr. spatulate-oblong. April. Texas to Ariz. and New Mex. S.S. 6:260.—Handsome flowering tree for temperate regions.

CC. *The corolla wanting, or occasionally present; calyx often irregularly toothed.* (*Ornaster.*)

8. **chinénsis,** Roxbg. Tree, to 40 ft.: branchlets glabrous: winter-buds brownish black, conspicuous with a rufous woolly tomentum when opening: lvs. 5–8 in. long; petiole enlarged at the base, nearly glabrous; lfts. 5–7, short-stalked, elliptic to elliptic-oblong or ovate-oblong, acuminate, cuneate at the base, serrate, dark green above, light green below and hairy along the lower part of the midrib, 2–5 in. long: pistillate panicle 3–6 in. long: fr. oblanceolate, obtuse or emarginate at the apex, 1½ in. long and ¼in. broad. China. May. Var. **rhynchophýlla,** Hemsl. (*F. rhynchophýlla,* Hance). Lfts. entire or irregularly crenate-serrate, on slenderer stalks. Cent. and W. China. G.F. 6:485.

AA. *Fls. from leafless axillary buds, before the lvs.; without corolla; filaments usually shorter than anthers.*

B. *The fls. diœcious, with the calyx persistent on the fr.; anthers linear or linear-oblong: lfts. generally 5–7: buds brown.* (*Leptalix.*)

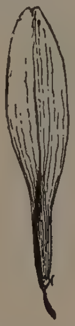
C. *Lvs. always pinnate.*

D. *Fr. oblanceolate or lanceolate; its body terete.*

E. *Lfts. stalked.*

F. *Under side of lfts. glaucous: wing of the fr. not decurrent.*

9. **americàna,** Linn. (*F. nòvæ-ángliæ,* Mill. *F. álba,* Marsh.). White Ash. Fig. 1575. Tall tree, to 120 ft.: branchlets and petioles glabrous: lfts. generally 7, stalked, ovate to ovate-lanceolate, entire or denticulate, dark green above, glaucous beneath, 3–5 in. long: fr. linear-oblong, with terete body, the wing not decurrent, 1½ in. long. From Canada to Fla., west to Minn. and Texas. S.S. 6:268. Em. 377. G.F. 7:405. F.E. 23:427.—Very variable. Var. **acuminàta,** Wesm. (*F. acuminàta,* Lam. *F. epíptera,* Michx. *F. americàna* var. *glaùca,* Hort.). Lfts. dark green and shining above, very glaucous and almost glabrous beneath, usually entire. Var. **juglandifòlia,** Rehd. (*F. juglandifòlia,* Lam.). Lfts. less shining above, usually broader, more or less pubescent beneath, serrate at least above the middle. This is the northern form, while the former is more common in the southern states. Var. **iodocárpa,** Fern. Frs. conspicuous by their reddish purple color. Var. **álbo-marginàta,** Hort. Lfts. edged white.



1575. Fruit or key of Fraxinus americana. (Natural size)

10. **Biltmoreàna,** Beadle. Tree, to 50 ft.: branchlets and petioles pubescent: lfts. 7–9, ovate-oblong to lanceolate, often falcate, acuminate, rounded or broadly cuneate at the base, entire or obscurely toothed, dark green and glabrous above, glaucous below and pubescent, particularly on the veins, 3–6 in. long: panicles pubescent: fr. linear-oblong, with terete body, the wing not decurrent, emarginate at the apex, 1½–1¾ in. long. May. Pa. to Ga., west to Ala., Mo. and Ill. S.S. 14:716.

FF. *Under side of lfts. green or grayish green: wing of the fr. decurrent, hence body margined.*

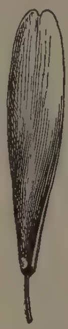
11. **lanceolàta,** Borkh. (*F. víridis,* Michx., in part. *F. pennsylvánica* var. *lanceolàta,* Sarg.). Green Ash. Tree, to 60 ft: branchlets and petioles glabrous: lfts. 5–9, stalked, ovate to oblong-lanceolate, irregularly serrate, green on both sides, almost glabrous, 2–5 in. long: fr. oblanceolate, with decurrent wing, hence body margined, about 1½ in. long. Canada to Fla., west to Rocky Mts. S.S. 6:272.

12. **pennsylvánica,** Marsh. (*F. pubéscens,* Lam.). Red Ash. Tree, to 60 ft.: branchlets and petioles pubescent: lfts. 5–9, stalked, ovate to oblong-lanceolate, acuminate, crenately serrate or entire, pubescent beneath, 3–6 in. long: fr. linear-spatulate, about 2 in. long, with somewhat decurrent wing. Canada to Fla., west to Dakota and Mo. S.S. 6:271.—This species varies considerably in the amount of pubescence and the shape of the lfts., and many forms under different names are grown in European nurseries and gardens. Var. **aucubæfòlia,** Hort., is a form with less pubescent lvs., blotched yellow. There are also variegated forms with the lvs. blotched white or edged white.

EE. *Lfts. sessile or short-stalked: branchlets and petioles pubescent.*

13. **velùtina,** Torr. (*F. pistaciæfòlia,* Torr.). Tree, to 40 ft., with velvety pubescent, rarely glabrous branches: lfts. 5–9, sometimes reduced to 3 or even 1, short-stalked, oblong to lanceolate, usually acuminate, narrowly cuneate at the base, entire or remotely serrate, yellowish green, firm and thick at maturity, pubescent or nearly glabrous beneath, 2–4 in. long: fr. spatulate, with marginless body. Texas to Ariz. and New Mex. S.S. 6:267. G.F. 8:15. —*F. Tòumeyi,* Brit., with narrower more distinctly stalked lfts., is probably only a variety of this species. M.D.G. 1913:556; also S.S. 6:267 represents this variety.—Particularly recommendable for saline and alkaline soil, where but few trees will grow; not hardy N.

14. **oregòna,** Nutt. Tree, to 80 ft.: petioles sometimes glabrous at length; lfts. 7–9, almost sessile or short-stalked, oblong or elliptic, acuminate, entire or obscurely and remotely serrate, light green, 2½–6 in. long, thick and firm at maturity: fr. oblong-obovate, with decurrent wing, about 1½ in. long. Wash. to Calif. S. S. 6:276.



1576. Key of Fraxinus nigra. (Natural size.)

DD. *Fr. elliptic or broadly spatulate, body compressed with the wing all around.*

15. **caroliniàna,** Mill. (*F. platycárpa,* Michx. *F. tríptera,* Nutt.). Water Ash. Tree, to 40 ft., with pubescent or glabrous branches: lfts. 5–7, stalked, ovate or oblong, acuminate, broadly cuneate or sometimes rounded at the base, serrate, rarely entire, pubescent or glabrous beneath, 2–5 in. long: fr. 1–2 in. long, with pinnately veined wing, often 3-winged. Va. to Fla., west to Ark. and Texas. S.S. 6:274, 275.

CC. *Lvs. usually simple, occasionally 3–5-foliolate: branchlets quadrangular.*

16. **anómala,** Wats. Shrub or tree, to 20 ft.: lfts. broadly ovate or roundish at the apex, rounded, acutish or emarginatc, entire or sparingly crenate-serrate, glabrous and dark green above, paler and pubescent below while young, 1½–2 in. long: fls. polygamous: fr. obovate-oblong, rounded or emarginate at the apex, ⅔in. long. Colo., Utah, Nev. and S. Calif. S.S. 6:266.

1577. Fraxinus excelsior. (×⅕)

BB. *The fls. without calyx (only No. 17 has a deciduous minute calyx); anthers cordate, rarely broadly oblong: lfts. generally more than 7, nearly glabrous. (Fraxinaster.)*

C. *Branches 4-angled and usually winged.*

17. **quadrangulàta,** Michx. Blue Ash. Tree, to 80, rarely 120 ft.: lfts. 7–11, short-stalked, ovate to lanceolate, acuminate, sharply serrate, yellowish green on both sides, 3–5 in. long: fls. perfect: fr. oblong, emarginate, winged all around, 1–2 in. long. From Mich. to Ark. and Tenn. S.S. 6:263.

CC. *Branches terete or nearly so.*

D. *Rachis at the base of lfts. with thick rufous tomentum: fls. diœcious.*

18. **nìgra,** Marsh. (*F. sambucifòlia,* Lam.). Black Ash. Fig. 1576. Tree, to 80 ft.: lfts. 9–11, sessile, oblong-lanceolate, rounded at the base, acuminate, sharply serrate, green on both sides, dark above, 3–6 in. long: anthers broadly oblong: fr. narrow-oblong, with decurrent wing. From Canada to Va., west to Mo. S.S. 5:264,265. Em. 382.

19. **mandschùrica,** Rupr. (*F. nìgra,* var. *mandshùrica,* Lingelsh.). Tree, to 100 ft., with obtusely quadrangular branches and dark brown buds: lfts. 9–11, almost sessile, ovate to oblong-lanceolate, sharply serrate, pubescent or hispid on the veins beneath, 3–6 in. long: fr. oblong-lanceolate, 1–1½ in. long. Manchuria, Korea, Saghalin, Japan. S.I.F. 2:62 (as *F. Sieboldiana*).

DD. *Rachis without conspicuous rufous tomentum: fls. perfect or polygamous.*

E. *Buds black.*

20. **excélsior,** Linn. Fig. 1577. Tall tree, to 120 ft.: lfts. 9–13, almost sessile, oblong-ovate or ovate-lanceolate, acute or acuminate, serrate, dark green above, paler beneath, 2–5 in. long: fr. oblong, often emarginate, about 1½ in. long. Eu., W. Asia. H.W. 3:59, pp. 115, 116. Gn. 22, p. 273. F.E. 24:395. Many different varieties are cult., some of the most distinct being the following: Var. **álbo-marginàta,** Hort. Lfts. edged white. Var. **argéntea,** Loud. (var. *álbo-variegàta,* Hort.). Lfts. blotched white. Var. **lùtea,** Loud. Lvs. variegated with yellow. Var. **jaspídea,** Desf. Bark of the young branches striped pinkish white. Var. **aùrea,** Pers. With yellow branches. Var. **aùrea-péndula,** Loud. With pendulous yellow branches, but a somewhat weak grower. Var. **eròsa,** Willd. (Var. *asplenifòlia,* Kirchn. Var. *laciniàta,* Hort. Var. *elegantíssima,* Hort. Var. *scolopendrifòlia,* Hort.). Lfts. very narrow, incisely serrate and often almost linear. Var. **críspa,** Willd. (Var. *atròvirens,* Var. *cucullàta,* Hort.), with very dark green curled and twisted lvs.; of slow growth. Var. **diversifòlia,** Ait. (*F. heterophýlla,* Vahl. *F. simplicifòlia laciniàta,* Hort. *F. rùfa,* Hort., not Bosc). Lvs. simple or 3-parted, usually incisely dentate. Gn. 22, p. 273. Var. **monophýlla,** Kuntze (*F. monophýlla,* Desf. *F. simplicifòlia,* Willd.). Lvs. simple, ovate, serrate, rarely with 1 or 2 small lfts. at the base. Var. **nàna,** Loud. (Var. *polemoniifòlia,* Var. *globòsa,* Hort.). A compact, slow-growing, dwarf form with very small lvs. M.D.G. 1904:380. Var. **péndula,** Ait. With pendulous branches. One of the best pendulous trees

for forming arbors and shady seats. Gn. 39, p, 451; 68, p. 400.

EE. *Buds brown.*

F. *Lfts. sessile or nearly so.*

G. *Number of lfts. 3–5, rarely 7.*

21. **syrìaca,** Boiss. (*F. sogdiàna,* Dipp., not Bunge. *F. turkestànica,* Carr.). In cult. usually small tree, the branches with short internodes and lvs. therefore crowded, often in whorls of 3: lfts. lanceolate, acuminate, cuneate at the base, serrate, bright green and quite glabrous on both sides, 1½–2½ in. long: panicles 1½ in. long: fr. usually obovate-oblong, obtuse. Syria to Kurdistan.

GG. *Number of lfts. 7–13.*

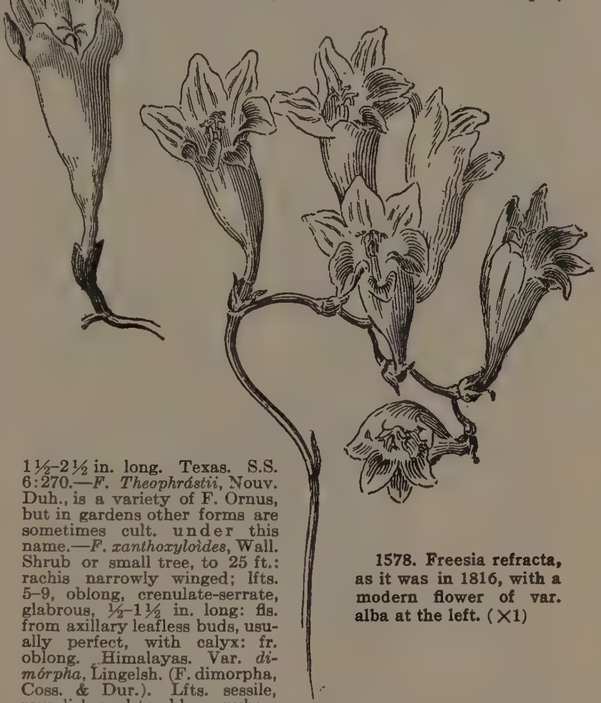
22. **oxycárpa,** Willd. (*F. oxyphýlla,* Bieb. *F. tamariscifòlia,* Hort., partly). Tree: lfts. 7–11, ovate-oblong to oblong-lanceolate, acuminate, cuneate at the base, sharply serrate, light green on both sides and glabrous except along the midrib below, 1½–3 in. long: fr. obovate-oblong, acute or obtusish, narrowed at the base. May. S. Eu. to Persia.

23. **rotundifòlia,** Mill. (*F. parvifòlia,* Lam. *F. lentiscifòlia,* Desf. *F. tamariscifòlia* Hort., partly). Shrub or small tree, to 15 ft., with slender, often purplish branches: lfts. 7–13, sessile, broadly oval to elliptic, rarely obovate, acute, or rounded at the apex, serrate, ½–1½ in. long: fr. oblong, obtuse or acute. W. Asia, S. Eu. Var. **péndula,** Rehd. (*F. parvifòlia* var. *péndula,* Dipp.), with pendulous branches, forming a graceful small weeping tree.

FF. *Lfts. distinctly stalked; stalk ⅕–⅖in. long.*

24. **potamóphila,** Herd. (*F. Règelii,* Dipp.). Small tree, to 30 ft., with rather stout, upright branches: lfts. 7–13, stalked, rhombic-ovate or ovate-lanceolate, serrate, acute or acuminate, glabrous or sparingly pubescent on the midrib below, 1–2½ in. long: fr. oblanceolate-oblong, with decurrent wing, acute, 1 in. long. Turkestan, Songaria.—Handsome tree with round head and dense small foliage.

F. angustifòlia, Vahl. Closely related to F. oxycarpa. Lfts. 7–13, elliptic-lanceolate to lanceolate, serrate, ½–1½ in. long: fr. obtuse at the base. S. Eu., N. Afr., W. Asia. Var. *austràlis,* Schneid. (F. australis, Gay). Lfts. below and rachis hairy.—*F. argéntea,* Loisel., is a variety of F. Ornus, not in cult., but in gardens often other ashes, especially variegated forms, are cult. under this name.—*F. austràlis,* Gay=F. angustifolia var. australis.—*F. Berlandieriàna,* DC. Allied to F. lanceolata. Tree, to 70 ft.: lfts. 3–5, ovate or obovate, serrate, downy along the veins beneath, to 4 in. long. Texas to Mex. S.S. 6:273.—*F. bracteàta,* Hemsl.=F. Griffithii.—*F. coriàcea,* Wats. Allied to F. velutina. Tree, to 30 ft.: lfts. 5, subcoriaceous, ovate to oblong, acute, broadly cuneate or rounded at the base, glabrous or pubescent below. S. Calif. to Utah, Ariz., Nev. S.S. 14:713.—*F. dimórpha,* Coss. & Dur.=F. xanthoxyloides var. dimorpha.—*F. dipétala,* Hook. & Arn. Allied to F. cuspidata. Shrub: lfts. 5–7, elliptic or ovate, serrate or entire, ½–2 in. long: fls. with 2 obovate petals. Calif., Mex. S.S. 6:261. Tender.—*F. floribúnda,* Wall. Allied to F. longicuspis. Tree, to 40 ft.: lfts. 5–7, ovate-lanceolate, serrate, reticulate beneath, 2–4 in. long: panicles large, to 10 in. long; petals oblong. Himalayas. Tender.—*F. floridàna,* Sarg.=F. pauciflora.—*F. Gréggii,* Gray. Allied to F. cuspidata. Small tree: lfts. 3–7, oblong-obovate, crenately serrate, or entire, ½–1 in. long: fr. linear-oblong, emarginate. S.S. 6:262. G.F. 2:451.—*F. Gríffithii,* Clarke (F. bracteata, Hemsl.). Allied to F. Mariesii. Tree, to 40 ft.: lfts. 5–7, subcoriaceous, elliptic to ovate-lanceolate, lustrous above, bright green below and pubescent on the veins, 2–4 in. long: infl. 6–8 in. high, with persistent lanceolate bracts; petals 4: fr. spatulate. Cent. China, Himalayas, Java.—*F. holotrícha,* Koehne. Allied to F. potamophila. Tree: lfts. 9–13, ovate-lanceolate or lanceolate, pubescent on both sides, 1½–3 in. long: fls. in 10-fld. racemes; ovary pubescent. Origin unknown.—*F. hýbrida,* Lingelsh.=F. pauciflora.—*F. pauciflòra,* Nutt. (F. floridana, Sarg. F. hybrida, Lingelsh.). Allied to F. caroliniana. Tree, to 40 ft.: lfts. 3–5, oblong, acuminate, cuneate at the base, tomentose below: fr. oblong-lanceolate, rounded or emarginate at the apex. Ga. to Fla. S.S. 14:717.—*F. Paxiàna,* Lingelsh. Allied to P. longicuspis. Tree, to 40 ft.: lfts. 7–9, sessile, ovate, crenulate, 4–7 in. long: panicle large and dense: fr. 1–1¼ in. long, ⅙in. broad. Cent. China, Himalayas.—*F. platýpoda,* Oliver. Allied to F. americana. Tree: petioles enlarged and winged at the base; lfts. 5–7, ovate-lanceolate, finely serrate, hairy along the midrib below, 2–4 in.: fr. narrow-oblong, acute. Cent. China. H.I. 20:1929.—*F. profúnda,* Bush. Allied to F. pennsylvanica. Lfts. 7–9, oblong-lanceolate, acuminate, entire, 3–6 in. long, tomentose beneath: fr. 2–2½ in., with decurrent wing. Ind., Ark., to Fla. S.S. 14:714–5.—*F. pubinérvis,* Blume. Allied to F. longicuspis. Lfts. usually 9, ovate to oblong-ovate, serrate with incurved teeth, pubescent on the veins below, 3–5 in. long: fr. oblanceolate. Japan.—*F. raibocárpa,* Regel. Shrub: lfts. 3–7, oblong or oblong-obovate, usually entire, obtuse, 1–2 in. long: fr. strongly falcate with obovate not decurrent wing. Turkestan, Bukhar.—*F. retùsa,* Champ. Allied to F. Mariesii. Tree: lfts. about 5, ovate to ovate-lanceolate, glabrous, reticulate, 2–3 in. long. Hongkong. Var. *Henryàna,* Oliver. Shrub or tree, to 35 ft.: lfts. slender-stalked, oblong to lanceolate, serrulate, 3–5 in. long: panicle dense, 4–6 in. long: fr. ¾–1 in. long, emarginate. Cent. China. H.I. 20:1930. Only the variety is in cult.—*F. sogdiàna,* Bunge. Allied to F. potamophila. Lfts. 7–11, ovate-lanceolate, bright green: fr. 1¼ in. long, obtuse or emarginate. Turkestan.—*F. texénsis,* Sarg. Allied to F. americana. Tree, to 40 ft.: lfts. 5, broadly oval or ovate, rounded or acute at the apex, 1½–2½ in. long. Texas. S.S. 6:270.—*F. Theophrástii,* Nouv. Duh., is a variety of F. Ornus, but in gardens other forms are sometimes cult. under this name.—*F. xanthoxyloìdes,* Wall. Shrub or small tree, to 25 ft.: rachis narrowly winged; lfts. 5–9, oblong, crenulate-serrate, glabrous, ½–1½ in. long: fls. from axillary leafless buds, usually perfect, with calyx: fr. oblong. Himalayas. Var. *dimórpha,* Lingelsh. (F. dimorpha, Coss. & Dur.). Lfts. sessile, roundish oval to oblong, pubescent on the midrib below. N. Afr. Var. *dumòsa,* Lingelsh. (F. dimorpha var. dumosa, Carr.). A low shrubby form of the preceding variety, with small lfts.—This species belongs to the section Sciadanthus, having perfect apetalous fls. with calyx.



1578. Freesia refracta, as it was in 1816, with a modern flower of var. alba at the left. (×1)

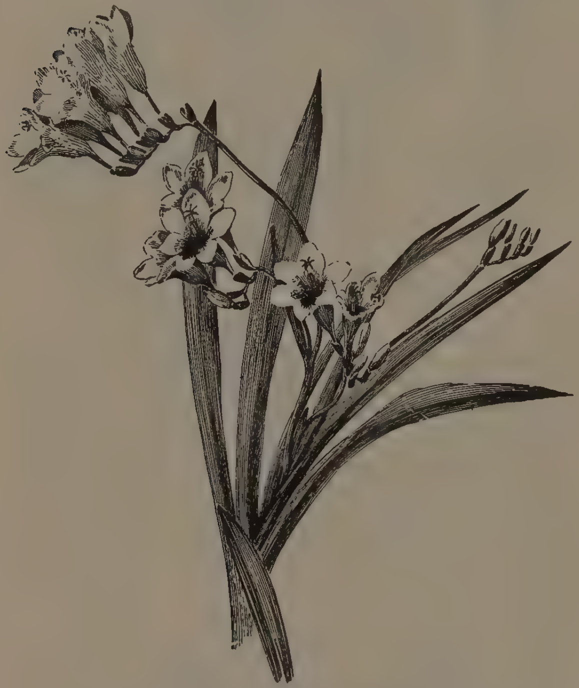
Alfred Rehder.

FREÈSIA (name unexplained, perhaps personal). *Iridàceæ.* Popular "bulbs" for fall planting and winter blooming, and next to the Chinese narcissus, which may be grown in water, they flourish in home windows with less care than most other bulbs; they are also much-prized florists' plants; easily grown, attractive, and fragrant.

Cormous plants, with plane narrow lvs. at the base and somewhat on the sts., and showy fls. in small clusters at the top of the slender st.: perianth tubular and funnel-shaped, the segms. more or less unequal; stamens 3, inserted in the tube, the anthers linear; ovary ovoid or oblong, 3-celled, with crowded ovules, the style filiform and the branches 2-fid (Tritonia, closely allied, has simple style-branches): fr. a loculicidal 3-valved caps., bearing turgid seeds.—S. Afr., probably 2 or 3 original species, but the specific limits difficult of determination.

Freesias have well-shaped tubular flowers, white or pale yellow. The five to seven flowers are upright and attached along a jointed axis which is suddenly bent back almost at right angles to the vertical peduncle. The popularity of freesias is a growth of the last quarter century or more, although they have been in cultivation since 1816 or earlier. Conservative botanists now suppose that the usual garden freesias are all originally of one stock, which species should be called *F.*

refracta. Extremes of variation in form are shown in Figs. 1578 and 1579, from the long and slender tube of var. *alba* to the short and broader tube of var. *Leichtlinii.* One of the earliest pictures of the plant is that in the "Botanical Register" for 1816 (Plate 135, as *Tritonia refracta*), a part of which is reproduced in Fig. 1578 to show the great irregularity of the corolla-lobes at that early period, and the straggling habit of the flowers, some pointing down and others up. The garden evolution of the freesias has proceeded along two lines. The greatest effort has been expended to produce a pure white flower, and in the best strains the white color is mostly associated with a long and slender tube. The ideal of a yellow flower is less popular, and is mostly associated with the shorter and broader tube. In both cases the forms with straggling inflorescence and irregular corolla-lobes have been suppressed. One may readily see how strongly two-lipped and gaping were the flowers of 1816, and how much the tube was bulged on one side. Any tendencies toward such forms in modern bulbs are signs of undesirable characters. In pedigree plants the lobes are rounded and the flowers symmetrical.



1579. Freesia refracta var. Leichtlinii. (×½)

These plants are much forced by florists, chiefly for cut-flowers at Christmas. If cut when only two flowers are out, the others will open. They may be had in flower from Christmas until June by successional plantings from August to February. For the best results the largest and highest-priced bulbs should be planted as early as August. Under good care, the bloom may be secured in ten to twelve weeks after the bulbs are planted; it is not necessary that the bulbs be kept cool or stored for a time after potting, as is the case with hyacinths and tulips, for they root quickly and start rapidly into growth. For holiday bloom, the bulbs are planted in October. One of the strong points of freesias is that planting may be delayed longer than with many other bulbs. Bottoms may be dried off gradually in the pots and then be shaken out and kept dry during summer. Repot; the larger bulbs will bloom, but will not give so good results as medium-sized imported bulbs not previously forced. When the plants are growing, keep them cool and moist. Provide good drainage, and let the potting earth contain a little sand and more or less fibrous material. Usually several bulbs are planted together in pots or boxes (about six bulbs in a 5-inch pot). Offsets are freely produced and these may be used for propagation; or seeds may be employed, giving blooming plants in two or three years, or sometimes the recent hybrid forms are said to give bloom in six to seven months from seeding.

refrácta, Klatt. Fig. 1578. Weakly erect, 1–1½ ft., from an ovoid reticulated corm, the st. more or less distantly branched and bearing a few reduced lvs: the basal lvs. about 6, linear, firm, about 6 in. long: fls. in loose secund spikes on a flexuose rachis, the spathe-valves oblong-lanceolate and acute and not covering the ovary; perianth greenish yellow or bright yellow, to 1½ in. long, the tube abruptly constricted below the middle, the limb distinctly labiate and the segms. unequal. B.R. 135 (as *Tritonia refracta*).—The original type is probably no longer in cult. Var. **álba,** Baker (*F. álba,* Hort.). Lvs. broader: infl. less branched; spathe-valves broader, toothed, covering the ovary; fls. large, clear white, with a gradually narrowing tube, the perianth-limb not bilabiate (or only indistinctly so), the segms. obtuse and nearly equal. G. 5:97; 8:575; 27:88. G.M. 50:927. Gn.W. 15:10. J.H. III. 43:272. The common garden form, much prized. *F. virginalis grandiflora* is a seedling of this, the fls. being much larger, ground-color white and less yellow in throat. G. 31:215. Var. **odoràta,** Baker (*F. odoràta,* Klatt). Lvs. broader than in the type, less rigid, and infl. less branched and fls. fewer: spathe-valves broader and more obtuse, toothed at the apex, covering the ovary; fls. bright yellow, the tube abruptly constricted, the limb not distinctly bilabiate and the segms. obtuse and nearly equal. L.B.C. 19:1820 (as *Tritonia odorata*). Var. **Leíchtlinii,** Hort. (*F. Leíchtlinii,* Klatt), (Fig. 1579), differs in its shorter abruptly constricted tube and large pale yellow fls.; by many considered to be a distinct species.

Ármstrongii, W. Wats. Differs from *F. refracta* in the color of the fls. and absence of purple from the lf.-bases: 16–20 in.: tube white with orange at base, the segms. markedly bordered with rose-purple: about one month later in blooming then *F. refracta alba.* Named for W. Armstrong, of S. Afr. Gn. 59, p. 374. G.M. 48:833.

hýbrida, Hort. Here belong many hybrid forms, some of them known as the "colored freesias," as: *F. Chápmanii,* a cross of the typical *F. refracta* (*F. aurea,* Hort.), with var. *alba,* producing a soft yellow flushed with deeper yellow and with an orange blotch (Gn. 71, p. 165. G.M. 50:164. G. 31:175); *F. Tubérgenii,* being a cross of *F. refracta alba,* and *F. Armstrongii* (G.W. 13, p. 199. G. 28:215. Gn. 69, p. 184. J.H. III. 52:299); *F. kewénsis,* hybrid probably between *F. Armstrongii* and *F. Leichtlinii; F. Màidenii,* being *F. refracta alba* × *F. Armstrongii; F. Ragionièri,* a race resulting from the crossing of *F. refracta, F. Leichtlinii* and their hybrids with *F. Armstrongii,* described as producing scented fls. tinted in shades of pink, rose, purple, blue, brown, orange, and spotted and veined.

L. H. B.†

FREMÓNTIA (after John Charles Fremont, distinguished western explorer, who discovered it in 1846). Syn. *Fremontodéndron. Sterculiàceæ.* Ornamental woody plant, grown chiefly for its showy yellow flowers.

Deciduous shrub or small tree with stellate pubescence: lvs. alternate, slender-petioled, palmately lobed: fls. solitary on short, lateral branchlets, apetalous; calyx large, deeply 5-parted, with 3 small bracts at the base; stamens 5, connate toward the base into a tube; ovary superior, inclosed by the staminal tube; style filiform: fr. a 5-celled, hirsute, dehiscent caps. with many seeds.—One species in Calif., allied to the Mexican Cheiranthodendron. Its bark is sometimes used as a substitute for that of the slippery elm and the plant is therefore locally known under this name.

This is a beautiful free-flowering shrub, with rather small, palmately lobed leaves and large yellow flowers appearing in great profusion in June. It is not hardy North, and in cooler regions it should have a sunny and sheltered position, preferably against a wall of southern aspect; it prefers well-drained, rather dry soil, and dislikes, especially during the winter, an excess of moisture. Propagation is by seeds or by greenwood cuttings under glass in summer.

califórnica, Torr. (*Fremontodéndron califórnicum,* Coville). To 20 ft.: lvs. generally roundish ovate, cordate or rounded at the base, obtuse, 3–5-lobed or almost entire, whitish or ferrugineous pubescent beneath, ¾–1½ in. long: calyx 1½–3 in. across, deep yellow, with stellate hairs outside, villous at the base within; lobes orbicular: caps. densely beset with hispid hairs, 1 in. long. S.S. 1:23. B.M. 5591. Gn. 3, p. 55; 22, p. 115; 29:8; 33, p. 566. G. 5:397; 32:457. G.M. 50:29. F.S. 22:2349. R.H. 1867:90. I.H. 13:496. B.H, 17:13.

Alfred Rehder.

FREYCINÈTIA (Chas. Louis de Freycinet, 1779–1842, French navigator). *Pandanàceæ.* Climbing or straggling shrubs sometimes seen under glass and perhaps planted far S., but apparently not in the American trade. The sts. are often prolonged, rooting: lvs. sheathing at base, the free part long and narrow, carinate, serrate or entire: fls. diœcious, in terminal fascicled spadices surrounded by fleshy leafy often colored bracts; males consisting of several stamens with short filaments; females of many 1-celled many-ovuled densely packed ovaries: fr. an oblong mass of fleshy or hard drupes.—Species above 50, islands of the Pacific, Austral., New Zeal. *F. Bánksii,* Cunn., is a tall climber, sometimes attaining the tops of high trees, with many stout branches, the arching lvs. to 3 ft. long and most abundant toward the ends of the branches: fl.-bracts numerous and leafy, the inner ones with thick succulent bases, sweet, and often eaten in New Zeal., where the plant is native: fr. rather fleshy, brown at maturity, ⅓in. long, edible. B.M. 6028. *F. Cumingiàna,* Gaud., of uncertain nativity, is more slender, lvs. not arching and divaricate. The freycinetias are little grown indoors as they require much room. They may be used as pillar plants. Prop. by offsets. L. H. B.

FRINGE-TREE: *Chionanthus virginica.*

FRITILLÀRIA (Latin *fritillus,* commonly understood to be a checker-board, but may have meant dice-box). *Liliàceæ.* Fritillary. This group includes the crown imperial and the fritillaries, hardy bulbous plants, mostly low-growing and spring-blooming, with drooping or nodding flowers which are often checkered or tessellated with dark purple and green, but some also with brighter colors.

Various leafy-stemmed simple herbs, the st.-lvs. narrow, sessile, alternate or whorled, the bulb mostly of few fleshy scales: perianth deciduous, mostly bell-shaped or sometimes bowl-shaped, the segms. nearly or quite equal, oblong or ovate, all or the inner ones with a nectar-bearing cavity or area at the base; stamens 6, with slender filaments and linear or oblong anthers; ovary 3-celled, nearly or quite sessile: fr. an ovoid or subglobose loculicidal winged or angled caps., with numerous seeds.—Species perhaps 70, widely distributed in the north temperate zone. Fritillaries resemble lilies in having drooping or nodding fls. but their anthers are fixed at the base, while those of the lilies are fastened on the back but are free to swing about. Lilies have funnel-shaped fls., while fritillaries and tulips have bell-shaped fls., and tulip fls. are erect. Nearly all the Old World fritillaries resemble tulips in having coated bulbs, while the American fritillaries resemble lilies in having scaly bulbs.

The most popular kinds are the checkered lily (*F. meleagris*) and crown imperial (*F. Imperialis*). Figs. 1582, 1583. These are hardy, easy to cultivate, and variable. The crown imperial is one of the most characteristic plants of old-fashioned gardens, but it has been banished from many modern gardens because of its strong fetid odor. It is the most robust species, and until lately was supposed to be the only one with its flowers in umbels, all the others being solitary or in racemes. It rejoices the children early in every spring by its pearly drops of nectar, which seem never to fall. *F. meleagris,* the most popular of the purple kinds, is the common snake's-head or checkered lily, so called from the tessellation of purple and green, which is prettiest when as sharply and regularly defined as possible. This plant grows wild in moist English meadows, and can be naturalized in large quantities in such situations. Other ancient inhabitants of European gardens are *F. latifolia, F. lutea* and *F. persica.* Other kinds are apparently less known in gardens. As a rule, the kinds that are chiefly purple or green, or mixtures of both colors, are dull, unattractive and curious compared with the few kinds that have brilliant yellow or red. Of the duller and purple kinds, two of the choicest, next to *F. meleagris,* are *F. tulipifolia* (which is flamed like a tulip and never checkered) and *F. camtschatcensis,* great masses of which in Alaska make one of the "summer sights" remembered by the tourists. The white in fritillaries is perhaps always more or less greenish, and the white color in *F. meleagris* is as good as in any species. A most brilliant species is *F. recurva,* which is also difficult of culture. Next in brilliancy come such species as *F. lutea, F. aurea, F. Moggridgei* and *F. pudica,* all highly individual and all yellow, some checkered, others not.

The culture of fritillaries is rather various, as some species are capable of being naturalized, some cultivated in borders, some in rockeries and others in pots. The crown imperial, being exceptionally vigorous, requires deep planting, rich soil and much room. The earth should be trenched. Well-rotted manure may be worked into the soil 6 inches below the bulbs and the bulbs set on a level 6 inches from the surface of the ground. If possible it should be shaded from the mid-day sun, as southern exposures are said to make the flowers smaller and shorter-lived. In border cultivation of fritillaries the essential peculiarities are a sheltered shady site, early fall planting, division every two or three years, and, as a rule, a warm, deep, sandy loam, which is not too cold or too retentive of moisture. Bulbs of the taller kinds may be planted 3 to 4 inches deep; bulbs of the dwarf kinds may be set at half that depth. As all fritillaries increase rapidly by offsets, it is desirable to lift and divide the plants at least every three years, or the small bulbs will rob the big ones. For the same reason, fritillaries are rarely propagated by seeds. The dwarf and rare sorts require more care and some leaf-mold in their soil, and some kinds require an evergreen carpet through which they may spring, as *Sedum hispanicum* or its var. *glaucum.*

Our native fritillaries, which include the bright-flowered *F. recurva* and *F. pudica,* are confined to the Pacific coast. Of these Carl Purdy makes two cultural groups, based on the character of bulb, the kind of soil and the conditions of shade. The first group contains *F. biflora, F. liliacea, F. pluriflora* and *F. Purdyi;* the second *F. atropurpurea, F. coccinea, F. lanceolata, F. parviflora, F. pudica* and *F. recurva.* The former grow in the sun in open fields in heavy clay soils; the latter in shady woods in well-drained soils, but *F. pudica* does not need so much shade as the others of its group, and must have sandy loam and slight shelter. The bulbs of the first group are composed of thick, heavy scales attached to a thin rhizomatous base, and the stems are 4 to 12 inches high and very leafy at the base; in the second group the bulbs are of one piece, and low-conical in form, their sides thickly covered with small, round, white rice-like offsets, and the slender stems are 1 to 3 feet high and leafy above the base. For the first group Purdy recommends a rich loam, and a slight shade to draw out the stems and prolong the bloom; for the second group a light, loose soil, rich in mold, a sheltered place and considerable shade. At the best these are not profuse in their bloom.

The key to the various subgenera here given is essentially Baker's in his monograph in Jour. Linn. Soc. 14:251 (1875); it rarely happens that the botanical and horticultural interests agree in using such simple and obvious characters as those of the bulb and style. The nectaries or glands are less useful and reliable, but they help to explain the natural groups in this varied genus.

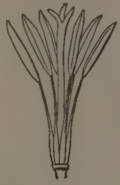
1. **meleàgris,** Linn. CHECKERED LILY. SNAKE'S-HEAD. Figs. 1580–1582. St. 1 ft. or more high: lvs. 3 or 4, linear or lanceolate, typically 1-fld.: fl. dull red with the inside checkered and spotted with higher color; segms. oblong, narrowed at both ends, about 1½ in. long, the inner ones bearing an oblong or linear cavity; fls. sometimes white or yellowish, or purplish and more or less checkered. England and Norway, through Cent. Eu. to Caucasus. Gn. 32:536; 47, p. 330; 52, p. 243.—The Dutch bulb-growers keep several kinds distinct. The extremes of color-range are (1) a greenish white, (2) a sufficient degree of purple to make the checkering as distinct as possible, and (3) an approach to yellow. Some kinds bear 2–3 fls.; some are double; some fls. spread so widely as to be almost funnel-shaped. Var. **álba,** Hort. White. G. 29:355. Gn.W. 21·221. Var. **contórta,** an old monstrosity, instead of segms. free all the way, and a shouldered base, has the lower third of the perianth united into a funnel-shaped tube. The yellow of some fls. is conjectured to be the result of a cross with *F. lutea* made before Gerarde's time. In England the species flowers toward the end of April G. 18:182; 35:273. J.H. III. 52:329. Gn.M. 10:117; 12:228. Gn. 61, p. 306 (vars.) G.M. 52:770.

2. **Whíttallii,** Baker. Height 1 ft.: st. 1-fld.: lvs. linear, glaucous: fls. checkered green and brown; nectaries orbicular. Mt. Taurus.

3. **tubæfórmis,** Gren. & Godr. (*F. delphinénsis,* Gren.). St. 6–12 in., often only 1-fld.: lvs. above middle of st. oblanceolate to linear: fls. wine-purple, spotted yellow and somewhat checkered, inodorous; segms. obtuse. Alps.—Distinguished by the glands 3–4 lines long and stigmas very short. Baker gives the same color-range as for *F. meleagris.* The most desirable form is var. **Móggridgei,** Boiss. (*F. Móggridgei,* Hort.), with bright yellow, checkered inside with bright red or reddish brown. This is a dwarfer form from the maritime Alps with wider lvs. (6–9 lines), longer stigmatic cusps, approaching *F. lutea,* and essentially yellow-fld. G.C. II. 13:533. Gn. 18:132. F.M. 1880: 405.—It blooms early. Var. **Burnàtii,** Planch., bright plum-color, checkered greenish yellow: fl. solitary, broadly bell-shaped, smaller, earlier and with smaller glands.



1580. Stamens and pistil of Fritillaria Meleagris.

From Flora Danica, showing the 3-cut stigma, an important character in this genus.

4. **verticillàta,** Willd. (*F. leucántha,* Fisch.). Height 1½ ft.: sts. simple, often 1-, sometimes 2–5-fld.: lvs. near the middle of the st., ovate and tapering toward the apex: fls. white or yellow, with small darker spots at the base. Altai Mts. B.M. 3083.—In the type the lvs. are numerous, 20–40: anthers barely half as long as the filaments: style no longer than the ovary, but in var. **Thúnbergii,** Hort. (*F. Thúnbergii,* Miq.), the upper lvs. are often sparse: anthers as long as the filaments; style 1½–2 times as long as the ovary. G.C. II. 13:532. It is doubtful whether the yellow-fld. form is cult.

5. **Walujèwi,** Regel. Probably belongs here, as its linear lvs. have tendrils: st. 1 ft.: fls. silver-white or lead-colored outside and crimson-brown spotted white or yellow inside. Turkestan. Gn. 52:243.

6. **ruthénica,** Wikst. Height 1–2 ft.: st. 1–3-fld.: lvs. 6–20, linear-lanceolate: fls. livid purple, obscurely checkered. Caucasus.

7–9. **lùtea,** Miller, and its allies **F. latifòlia,** Willd., and **F. aùrea,** Schott. These 3 names may be taken as representing the 3 well-marked types of color: *F. lutea* an intermediate form, essentially yellow, but greenish, and with the purple checker-marks duller in color and not so sharply defined and regular. *F. latifolia* representing the extreme of dark purple and green without yellow; *F. aurea,* at the other extreme, being essentially yellow, the checker marks smaller and more sharply defined, and the colors bright. In this sense the pictures may be referred to the types as follows: B.M. 1538 to *F. lutea;* B.M. 853 and 1207 to *F. latifolia;* B.M. 7374, R.H. 1878, p. 287, Gn. 42: 72, J.H. III. 28:357, to *F. aurea. F. latifolia* represents the extreme width of lvs., and *F. aurea* is said to differ in having the lower lvs. often whorled. All these grow ½–1 ft. high. One of the most anciently cult. of all fritillaries is *F. lutea,* which is found promiscuously mingled with the wider-lvd. form, both wild and cult. At present the most popular of the 3 is probably *F. aurea.* The Dutch bulb-growers advertise several varieties of *F. latifolia.* These 3 species are fom S. W. Asia.—*F. lùtea.* St. often 1-fld.: lvs. alternate, linear-lanceolate: fls. yellow, more or less marked or suffused with purple; segms. oblong-lanceolate. *F. latifòlia* (*F. luteo* var. *latifolia*) has

1581. Strange form of doubling in the checkered lily, pictured as early as 1613.

lanceolate lvs., the upper ones opposite: fls. purple. *F. aurea.* Lvs. 10–12, lower in 3's, linear, somewhat glaucous and fleshy: fls. solitary, bright yellow.

10. **pallidiflòra,** Schrenk. Height 6–15 in.: lvs. many, large and broad, glaucous-blue: fls. 1–6, yellow, handsomely tessellated inside. Siberia. B.M. 6725 (green, with a few dark purple spots). Gt. 6:328. R.H. 1880, p. 215. G.C. II. 19:573. Gn.W. 23:397.

11. **meleagroìdes,** Patrin. (*F. mìnor,* Ledeb.). Height 1–2 ft.: st. very slender, mostly 1-fld.: lvs. 3–6, narrowly linear: fls. dark purple, spotted green; anthers a third the length of the filaments. W. Siberia. B.M. 3280.

12. **pyrenàica,** Linn. Height 1–1½ ft., mostly 1-fld.: lvs. 6–10, linear, glaucous: fls. dark purple, spotted green; anthers two-fifths the length of the filaments. Pyrenees. B.M. 664, not 952 or 1216.

13. **oranénsis,** Baker. Height 1–1½ ft.: lower lvs. lanceolate; upper lvs. linear: fls. dark purple, obscurely checkered green. Mt. Oran. G.C. II. 13:341.

14. **Élwesii,** Boiss. Lvs. 5–6: fls. green, flushed purple on back and tips, not checkered. Lycia. B.M. 6321 (erroneously, as *F. acmopetala*). Gn. 65, p. 307. Gn.W. 21:445.

1582. Common Snake's-Head or Checkered Lily (Fritillaria meleagris).

Faithfully redrawn from Besler's Hortus Eystettensis, published in 1613. (Incorrect as to stamens and some other characters.)

15. **tulipifòlia,** Bieb. Height 2–8 in.: st. 1-fld.: lvs. 3–4, elliptic, concave, nerveless, 1½–2½ in. long: fls. solitary, inside rusty brown-purple, not checkered, outside dark glaucous blue, streaked with the same purple. Caucasus. B.M. 5969.—One of the choicest and daintiest kinds. Very distinct. Foliage glaucous blue: fls. resembling a tulip in shape, and with a chalky look outside.

16. **armèna,** Boiss. Height 6–12 in.: st. 1-fld.: lvs. 4–5, lower lanceolate, upper linear: fls. between funnel- and bell-shaped, dark purple, not checkered. Armenia. B.M. 6365. J.H. III. 35:83. Var. **fúsco-lùtea,** Hort., tawny yellow.

17. **pùdica,** Spreng. St. 2–10 in.: lvs. 3–8, lower ones strap-shaped, often opposite (while in *F. tulipifolia* and *F. armena* they are alternate), upper ones linear: fl. usually solitary, pale or dark yellow, rarely purple, never checkered; segms. oblong-spatulate and obtuse, more or less spreading. N. W. Amer. Gn. 13:598; 61, p. 337. R.H. 1895, p. 229. G.C. III. 19:403. J.H. III. 32:295. Mn. 4:49.—The stamens (as in Nos. 14 and 15) are nearly as long as the perianth. "Deep orange-yellow, fragrant."—Van Tubergen.

18. **Sewérzowi,** Regel. Height 1–1½ ft.: lowest lvs. lorate-lanceolate, 1 in. wide, often opposite, upper lvs. lanceolate, 6–7-nerved, 3–4 in. long: pedicels 3–6 lines long; fls. 6–10, green, not checkered, but with a few purple spots outside; filaments purple; anthers green. Turkestan. Gt. 760. B.M. 6371. J.H. III. 30:319. G.C. III. 1:457. Gn. 69, p. 133.

19. **pérsica,** Linn. Robust, 2–3 ft. high: lvs. 40–60, glaucous, linear, 4–6 in. long, 6–9 lines wide: raceme 10–50-fld.; fls. small bell-shaped, slightly odorous, lilac-purple, sometimes chalky outside and lined with purple but never checkered; stamens a trifle shorter than the perianth. Orient. Fls. end of April or beginning of May. B.M. 1537. Var. **mìnor,** Sims, B.M. 962 (excluding synonymy), has smaller fls. and anthers barely exserted.

20. **libanótica,** Baker. Closely resembling No. 19, but with 6–30 strongly odorous fls., pale lilac, with darker vertical veins; stamens a third shorter than the perianth; anthers purplish. Palestine, rocky and shady parts of Mt. Lebanon.

21. **pluriflòra,** Torr. Pink Fritillary. Height 6–12 in.: lvs. few, mostly at the base, oblong-lanceolate, about 4 in. long: raceme 4–12-fld.; fls. rosy purple, not checkered, the glands not evident; stigma shortly 3-lobed. Calif. G.C. III. 21:231.—Blooms early. **F. Púrdyi,** Eastw., differs in the fl. being white beautifully tinged purple. Humboldt Co., Calif.

22. **lanceolàta,** Pursh. Sts. 1–3 ft.: lvs. 4–10, lanceolate, whorled on the upper part of st. (or sometimes scattered), ovate-lanceolate, 2–4 in. long: fls. 1–4, bowl-shaped, dark purple mottled greenish yellow, somewhat variable in color; segms. ovate to oblong, concave, with large gland. Calif. Var. **grácilis,** Wats. Fls. very small with narrow and more acuminate segms., deep purple or almost black. Var. **floribúnda,** Benth. (*F. mùtica,* Lindl.). Fls. 3 to many, dark purple or greenish and conspicuously spotted or checkered, the segms. crisped or erose.—The bulbs of *F. lanceolata* live one year; the scales are few or none, and the bulb is covered with rice-like bulblets (whence the name "rice-root lily").

1583. The Crown Imperial.—Fritillaria Imperialis.

23. **parviflòra,** Torr. St. 5–20-fld.: lvs. about 9, mostly whorled, linear: fls. purple, suffused green, not checkered, on short and strongly recurved pedicels; segms. with shallow nectaries. Sierra Nevadas in Calif.

24. **atropurpùrea,** Nutt. St. 1–6-fld., lower and more slender than in No. 23: lvs. 12–20, scattered or imperfectly whorled: fls. dark purple obscurely checkered with green, on slender pedicels. Wyo. and Utah, to the Sierras and the Columbia River.

25. **coccínea,** Greene. Scarlet Fritillary. St. 1–4-fld.,

slender, 12–18 in. high: lvs. 3–7, in 2 or 3 whorls at middle of st., narrow-linear: fls. scarlet, slightly mottled within with yellow. Calif.—Said to be very like *F. recurva*, but lower and less leafy and the fls. of different color; it has a smaller bulb and takes more readily to cult.

26. **Imperiàlis,** Linn. (*Imperiàlis coronàta*, Dum. Cours.). Crown Imperial. Fig. 1583. Height 2–3 ft.: lvs. numerous, crowded, ascending, ½–1 in. wide, highest often in whorls of 8–10: fls. end of March. B.M. 194 and 1215. Gn. 46, p. 101; 52, p. 243. A.G. 13:488. R.B. 20:196.—There are single and double forms in yellow and red, and kinds with foliage striped white, and with gold. There are varieties Aurora, Maximus, and William Rex, red; Sulphureus, sulfur-yellow; and Crown upon Crown, Couronne Orange, Red Slagzwaard and others. Var. **longipétala,** Hort. Gn. 56:358, with long segms. Var. **chitralénsis,** Hort., has rich yellow fls.: said to be a common form in Chitral (British India). G.C. III. 47:171. G.M. 54:682. **F. Raddeàna** Regel, from Turkestan, is somewhat dwarfer, blooms earlier, has floral lvs. recurved-spreading, fls. straw-colored or greenish yellow and shorter than the pedicels.

27. **recúrva,** Benth. Height 6–24 in.: st. 2–8-fld., purple, mottled green: lvs. 6–12, lower ones in whorls of 3–4, linear, ascending: fls. narrow, bell-shaped. Calif., Ore. B.M. 6264. Gn. 18:458; 59, p. 415; 61, p. 336. —This has stamens only a little shorter than the perianth, while in the next 3 species they are only half the length of the perianth. Distinct by the color of the fls., which are bright red outside without a trace of purple, and brilliant yellow inside, spotted with red.

28. **liliàcea,** Lindl. White Fritillary. Height 3–12 in.: st. 1–6-fld.: lvs. on st. few, linear-oblong or linear, those of the radical tuft narrowly or broadly oblong: fls. between funnel- and bell-shaped, whitish, veined green, not checkered; gland at base of segms. greenish and purple-dotted. Calif. in Coast Range from San Francisco south. Gt. 1871:715.

29. **biflòra,** Lindl. Black Lily. Chocolate Lily. Height 6–18 in., stout: st. 1–3-fld.: lvs. 2–6, most of them near the base, scattered or whorled, oblong: perianth greenish or dark purple or lined with purple; segms. elliptic-obovate, with a greenish longitudinal band. S. Calif.—Fls. often described as dark chocolate-brown to nearly black.

30. **camtschatcénsis,** Ker-Gawl. Mostly written *kamtschatcensis* and variously misspelled. (*Lílium camtschatcénse*, Linn.). Black Lily. Height 6–18 in.: st. 1–3-fld.: lvs. 10–15, lanceolate, the lower ones whorled: fls. livid wine-purple, not checkered, 1¼ in. or less long. Siberia, Alaska. Gt. 5:290. Gn. 25:232; 52, p. 242. F.S. 12:1232. G. 14:362.

F. agréstis, Greene. Bulbs very deep-seated: sts. 1–1½ ft.: lvs. 8–12, oblong-lanceolate to linear-lanceolate: fls. 3–8, on abruptly recurved pedicels, yellowish green, with prominent midnerve on each segm. Calif.—Said by Purdy to occur in 2 forms, one a dainty plant a few inches high with fls. having light green or yellow base-color and heavily lined with brown (Mendocino Co.); the other a foot or two tall and similarly marked, so fetid as to be called "stink bells" (edge of San Joaquin Valley, Contra Costa Co.). Probably not in cult.—*F. askabadénsis*, Mich. St. about 3 ft.: upper lvs. linear-lanceolate, whorled: fls. 5–8, hanging amongst the uppermost lvs., about 1 in. long, bell-shaped, pale yellow-green. Cent Asia. B.M. 7850. G.C. III. 31:238; 45:184. Gn. 61, p. 256. G.M. 45:745. R.H. 1903:180. J.H. III. 44:293. F. S. R. 1:134.—*F. cònica*, Hort. Lvs. in a rosette: fls. bell-shaped, pale yellow outside and bright yellow inside. Greece.—*F. póntica*, Wahl. St. tall, 1½ ft., leafy at middle, the lvs. broadly lanceolate, lower ones opposite: fls. yellow-green, margined and tipped red, the segms. bearing nearly orbicular nectaries. Asia Minor. Gn.W. 21:407.—*F. tuntàsia*, Heldr. St. 8–10 in.: lvs. long and glaucous: fls. 4–6, bell-shaped, about 1 in. across, intense dark maroon. Greece. Gn.W. 23:435.—*F. Záhnii*, Hort. Fls. bell-shaped, rather large, brown, checkered with green inside and streaked with yellow outside. Greece.

Wilhelm Miller.

FRŒLÍCHIA (J. A. Froelich, physician of Ellwangen, Germany, monographed Gentiana in 1796; died 1841). *Amarantàceæ.* About a dozen species of woolly or hairy American annuals, found chiefly in W. Indies, Mex. and Brazil, scarcely planted: lvs. opposite, entire or nearly so: spikes opposite, terminal; fls. perfect, 3-bracted; calyx tubular, 5-cleft, hardened and spiny-crested in fr.; stamens 5, with united filaments: fr. an indehiscent utricle, inclosed in the filament-tube. **F. floridàna,** Moq., has been advertised for sale in Amer. It is cult. abroad. Height 1–4 ft., leafless above: lvs. linear to oblong or lanceolate: spikes 2 in. long or more; fls. white and woolly, set off by small blackish bracts: fr. broadly winged and irregularly toothed. July–Sept. B.M. 2603 (as *Oplotheca floridana*). Dry sandy areas, Del. to Fla., and west. *F. campéstris*, Small, is by some authors considered not to be distinct.

L. H. B.†

FROST. Hoar frost or white frost is ice deposited upon the surface of plants or other objects. Sometimes it consists of frozen dew-drops, sometimes of feathery spinelike ice-crystals, but usually both formations are present. The moisture from which the deposit of ice is formed comes partly from the ground, partly from the air, and in the case of plants, probably partly from the plant itself.

The term "black frost" is used when plants are frozen without the appearance of any deposit of ice upon them. It occurs when the temperature falls below the freezing-point (32° F.), but not low enough to cause the moisture in the air to come out in the form of hoar frost.

The term "frost," when unqualified, means simply temperatures that are injurious to vegetation without regard to any deposit of ice. It is in this sense that the term "frost" is used in this article.

Degrees of frost.

With respect to the effect of frost on vegetation, the Weather Bureau recognizes three degrees of frost—light, heavy, and killing. A light frost is recorded when only the tenderest plants are injured; a heavy frost, when the injury to tender plants is more marked and the hardier plants are damaged; and a killing frost, when the staple products of the region are injured severely or are killed. When no deposit of frost occurs and the temperature of the air as indicated by the thermometer falls during the night to 32°, a killing frost is recorded also. Frost charts and frost tables, published by the Weather Bureau, are based on the records of killing frosts only.

How plants are injured by frost.

When ice appears on the leaves or blossoms of the plant, it is evidence that the temperature of the plant is at or below the freezing-point; but if the temperature does not go below 32° F., or does not remain at that point too long, little injury will result to any temperate-zone plants. In fact, the phenomenon that we usually have in mind when we speak of killing by low temperature occurs only when ice forms within the tissue. Careful observers have found that the ice formed in the tissue is nearly always in the intercellular spaces, the water being withdrawn from the cells to form these crystals. Whether the withdrawal of water from the cell is the cause of death or is merely associated with it, is not certain. In case of winter dormant tissue, that is very resistant to low temperature, the injury at a given temperature is much greater when the temperature-fall is very rapid. In the case of a few tissues, like ripe apples and pears and leaves of *Agave americana* and of lettuce, the rapidity of thawing influences the extent of injury at the highest killing temperature of the tissue. However, it is not a determining factor, since, if the temperature be carried somewhat lower, the tissue will kill regardless of the rate of thawing.

Varieties as well as individual plants differ greatly in their ability to withstand cold, and a temperature that may destroy a plant at one time may cause little injury at any other time. Hence, no general statement can be made with regard to injurious temperatures that will apply in all cases.

The following table indicates the temperatures (Fahr.) that have been found injurious to tree fruits during the blossoming period:

Fruits	Petals closed	In blossom	Setting	Later
Apples	27	29	30	30
Peaches	20	25	28	30
Cherries	22	28	29	29
Pears	27	29	29	30
Plums	30	31	31	29

General atmospheric conditions that cause frost.

The loss of heat that brings the temperature of plants to the freezing-point occurs in two ways,—(1) loss by conduction, and (2) loss by radiation. Loss of heat by conduction occurs when the air in contact with the plant is colder than the plant itself. This allows the heat to flow directly from the plant into the colder air about it. Frosts due to this cause alone result almost invariably from the importation of large masses of cold air, brought down from the upper atmosphere by descending currents, or from higher latitudes by northerly winds, both of which movements usually are active when the weather clears after a storm.

Frosts, particularly in the late spring or early fall, result also from loss of heat by radiation. Plants radiate heat continuously. During the day more heat is received by them from the sun than they give off, and the plant becomes warmer; at night plants pour more heat into the atmosphere than they receive from it, hence they become colder.

Radiation proceeds most rapidly when the sky is clear and the atmosphere is quiet. Clouds check radiation, because the heat given off from the earth does not penetrate them easily. Much of it is reflected back toward the earth, warming the whole stratum of air between the earth and the clouds.

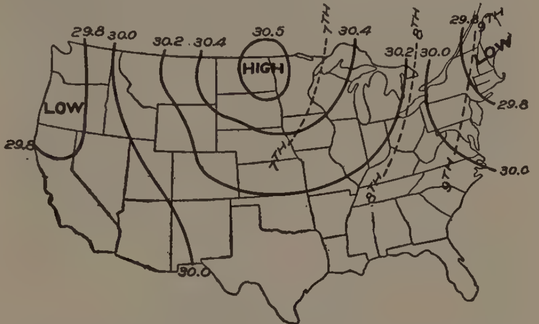
A quiet atmosphere allows the colder, therefore heavier, particles of air to settle to the surface of the earth. Thus, on quiet, clear nights, when frost is likely to occur, the air near the ground may be 10° colder than the air 10 or 15 feet above the ground. The wind, by stirring up the atmosphere, prevents the settling of the cold air, and in this way maintains the stratum of air near the surface at a more nearly uniform temperature.

Frost results seldom from conduction or radiation alone. Both usually are active when frost occurs.

Forecasting frost from weather maps.

Frosts that injure vegetation are a part of the regular weather sequences. The weather comes to us in what may be termed waves that travel with more or less regularity in the middle latitudes from west to east. The weather map is a survey of the atmosphere. It charts the daily progress of these weather waves. By the aid of such a chart it is possible to foresee in a measure the coming of a frost, and to judge its probable extent and severity.

The weather map is based on observations of pressure, temperature, cloudiness, wind, and precipitation, made at many places scattered over a large area. Low atmospheric pressure indicates the trough of the weather wave, and high pressure its crest. The low-pressure area is called the cyclone, because the winds whirl or eddy about its center, the direction of rotation being counter clock-wise in the northern hemisphere. In approaching the center, the winds have an ascending as well as an inward component of motion. The cyclone also is called a storm, because it is attended on its eastern side by southerly or easterly winds, cloudiness, rain or snow, and comparatively high temperature, and on its western side by northerly winds, clearing weather, and a decided fall of temperature.

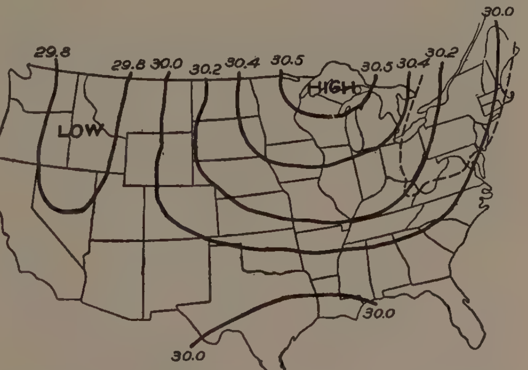


1584. Weather map, 8 a.m., June 7, 1913.

The crest of the wave is indicated by increased pressure, and is called the anti-cyclone. It is so named because its structure is exactly opposite to that of the cyclone. The winds of the anti-cyclone blow outward from its center, and have a downward component of motion; the sky is clear; the precipitation is scanty or absent; and the temperature is comparatively low.

Frosts are most likely to occur in the rear (western side) of the cyclone, and just in front (eastern side) of the crest or center of the anti-cyclone. Here is found the mass of cold air, imported from the north by the northerly winds, and augmented by the cold brought down from above by the gently descending currents; the sky is clear; and as night comes on the air becomes quiet. Thus, the conditions that cause frost are fulfilled.

A weather wave, in which frost was the most pronounced characteristic, moved from North Dakota to the Atlantic coast from June 7 to 10, 1913 (Fig. 1584). The general conditions on the morning of the 7th and 8th (Fig. 1585) are shown by the accompanying weather maps for those dates. The eastward progress of frost from day to day is indicated by the dotted lines on the map of the 7th. The relative position of the cyclone (low) and the anti-cyclone (high), on the 7th, indicates clearly that frosts will occur over the Upper Mississippi Valley and the Upper Lakes on the following morning, while the conditions shown by the map of the 8th make it certain that the frosts will spread eastward over New York and the New England states by the morning of the 9th.



1585. Weather map, 8 a.m., June 8, 1913.

The Weather Bureau issues frost warnings when frosts are indicated for any part of the United States.

The warnings are distributed by mail, telegraph and by telephone. They are telegraphed at Government expense to many telephone companies.

Forecasting frost from local observations.

It is not possible to forecast frost twenty-four or thirty-six hours in advance without the aid of the weather map; but, by observing the local conditions during the late afternoon and early evening, it is possible often to determine whether a frost will occur before morning. Assuming that it is the frost season, the conditions to be considered are: (1) the character of the preceding weather, (2) the state of the sky, whether cloudy or clear, (3) the direction and force of the wind, (4) the trend of the temperature, and (5) the atmospheric pressure.

Preceding weather.—Since the weather comes in waves, an abnormally warm period is likely to be followed by the opposite extreme.

State of the sky.—A clear sky increases loss of heat by radiation, as explained already.

Direction and force of wind.—A southwest to west wind indicates that the cyclone is passing (except perhaps on the Pacific coast, where other conditions may modify the directions), and that the anti-cyclone is approaching, while a northwest to north wind indicates that the anti-cyclone is near. If the wind dies away it will become colder near the ground.

Trend of the temperature.—If the temperature falls steadily during the late afternoon, reaching 40° by 6 or 8 P. M., with a clear sky and a light wind, frost is indicated before morning.

Atmospheric pressure.—The actual stage of the barometer is not important, except if the pressure has been very low during the day it indicates the passage of a deep depression which is likely to be followed by a high crest. If the barometer rises rapidly during the late afternoon or early evening it indicates the rapid approach of the anti-cyclone.

The influence of local conditions on frost.

Everyone who has lived in the open country is familiar with the fact that some places are more subject to frost than other places. Crops in one part of a field may be destroyed by frost, and in another part of the same field remain uninjured. The explanation for this seeming discrimination is found in the influence of local conditions.

There are five factors that determine the frost risk at any place: (1) location, city or country, (2) elevation and topography, (3) proximity to bodies of water, (4) exposure to the sun, (5) soil and soil coverings.

Location.—Frosts are much more likely to occur in the open country than in cities. Many investigations confirm this. The higher night temperatures of cities is attributed to the heat given off from buildings and pavements, and to the smoke from the many city fires that collects over cities on quiet nights.

Elevation and topography.—The average temperature decreases with elevation above sea-level at a rate of 1° for each 300 feet of ascent. From this it might be expected that hilltops would be more frosty than adjacent lower lands. Such is not the case. On clear quiet nights the colder air that settles to the surface drains away from the hilltops and hillsides and accumulates over the low lands, decreasing the temperature of the vegetation and sometimes causing frost. If the valley into which the cold air drains is closed, so that it cannot flow away as rapidly as it accumulates, a "frost pocket" results. Some farms have many such "frost pockets." A walk over a farm on a clear quiet night often will reveal their location and extent. Low hilltops and hillsides, but not too near the valley floor, should be chosen for fruits or other crops that are liable to be injured by frost.

Proximity to bodies of water.—Under similar conditions, land warms and cools about five times as rapidly as water. During the season of spring frosts, the water is relatively cool, although considerably above the freezing-point. Therefore, it tends to cool the air over adjacent lands during the day and to warm it at night. The influence of a body of water on nearby vegetation is twofold: by lowering the day temperature it retards growth, and by increasing the night temperature wards off frost. The fruit-belts along the various lakes are examples of this twofold influence. The cool air from the lake by day retards the blooming period, and also gives immunity from frost at night. The influence of a body of water is more marked in the fall than in the spring, because of the heat stored up by the water during the summer. It also increases the length of the growing season over adjacent lands by warding off frost both in spring and fall. The distance to which the influence of a body of water will extend inland depends upon the volume of water, its temperature relative to that of the land, the area of its free surface, the slope of its shores, and the prevailing winds. The prevailing winds in the middle latitudes are from the west. Thus, the influence of a lake extends farthest on its east side, and farthest also when the land slopes gently away from the water. The influence of Lake Michigan, mainly because of the gentle slope of its eastern shore, extends nearly half way across the state of Michigan, while the influence of Lake Erie, because of the abrupt rise of its eastern shore, extends inland only a few miles.

Exposure.—Hillsides exposed toward the south are warmest; next come those facing east, then west, and finally north. Frost liability follows in the reverse order, being greatest on the north side. In the eastern states many fruit-growers prefer the northern slope for an orchard site, notwithstanding its greater liability to frost. This preference is based partly on the opinion that the colder soil and air of northern slopes tends to retard the blooming time until the period of spring frosts is passed.

Soil and soil coverings.—Dark-colored, sandy soils, because good absorbers of heat, are least liable to frost. Many cranberry-growers cover the surface of the bogs with an inch or two of sand as a means of protecting from frost. The sand stores up heat by day with which to combat frost at night. Well-drained soils are less frosty than poorly drained soils, because, when the soil is wet, the heat from the sun is expended in evaporating the water, and not in warming the soil. Good tillage reduces the frost risk, because a loose, porous soil absorbs more heat than a hard, compact soil.

WILFORD M. WILSON.

The protection of orchards against frost-injury.

Although much interest has been manifested in the prevention of frost-injury to orchards in recent years, it is well known that the protection of plants and fruits from such injury dates back more than 2,000 years. Pliny the Elder, one of the most noted of Roman writers, who lived from 23 to 79 A.D., states that the Romans practised heating and smudging as a protection against frost-injury. We have no doubt that the practice was successful, since it was recommended by Pliny whose one surviving work, his "Natural History," is considered a storehouse of facts. Smudging was also recommended by Olivier de Serres, a French agriculturist, in the sixteenth century. He recommended the use of wet straw and half-rotten manures so as to produce a heavy smoke. In the latter part of the eighteenth century, the practice of smudging was compulsory in parts of Germany, and failure to comply with certain regulations resulted in prosecution before an officer of the law. According to Boussingault, the celebrated

French chemist, smudges have been used for centuries on the plains of Cuzco, Peru, on still clear nights by Indians, to retard the loss of heat from the soil. This practice was inherited by them from the pre-Spanish civilization. From the fragmentary pieces of literature we are able to find concerning the matter of frost-prevention, there is no doubt that the practice has been more or less common from the most remote times to the present day.

It is only in recent years, however, that the matter of frost-prevention has been scientifically investigated. The literature on the subject has been, until very recently, of very little importance, because the methods advocated were very crude and could not be used by the commercial fruit-grower. However, during the 1880's and early 1890's, the French vine-growers did some remarkable work. Even at that time, they used heavy oil and tar as fuels, placing these in flat ironware dishes much the same as the modern practice of using smudge-pots with crude-oil. There had also been devised systems of automatic lighting operated by a mercuric column, not very much unlike some of our more recently patented automatic alarm thermometers and self-lighters. About the same time that the French vine-growers were perfecting their work in frost-prevention, the California and Florida orange-growers were also making experiments along the same line. The first successful attempt to prevent frost-injury by the use of heating devices on a large scale occurred in California about 1896. Edward Copely is credited with inventing the wire coal-basket as well as a machine to make it cheaply. These baskets were filled with kindling and about twenty-five pounds of coal, twenty-five to thirty baskets being provided to the acre. They were suspended by wires to limbs of trees. The first use of oil of which there is a record was by Everett at Arlington, California; and the first use of hot water was by Meacham, at Riverside, California. Later, J. P. Bolton, of the United States Weather Bureau, stationed at Fresno, California, devised an oil-pot for use in the vineyards during the period of spring frosts.

1586. Method of protecting windward side of an orchard by doubling the number of orchard-heaters.

The occasion for considerable activity in the matter of frost-fighting at this time was due to a very severe frost in December, 1895, causing great damage to the orange and lemon groves in the Riverside section. It may be said that the beginning of frost-fighting in a commercial way dates from this time. The Riverside Horticultural Club in the winter of 1897–98 took an active interest, and many experiments were conducted, using all sorts of devices for adding moisture to the air by means of fires of damp straw and stable manure, evaporation of water by means of evaporating-pans, sprayers and sprinklers, and by irrigation of the orchards. Boilers were also used with connecting pipes whereby steam was generated and carried to the different parts of the orchards. Direct heating of the air by means of fires was also tried and proved to be the most successful method of preventing frost-injury.

The deciduous fruit-growers of the Sacramento Valley, California, also practised orchard-heating more or less successfully, adopting the methods employed by the citrus fruit-growers of the South. It is remarkable that some of this work did not bear so good results as it should. Fully ten years passed without any advance having been made in the methods of orchard-heating. About 1906, a renewed interest was taken in the work and since that time orchard-heating has been given scientific study. Within the last four or five years the fruit- and vegetable-growers throughout the United States have taken much interest in the practice of protecting their crops from frost-injury, and it has become a recognized part of orchard work in districts in which frosts regularly occur.

The literature on the subject has now assumed considerable importance since it is the result of scientific investigation of frost-injury and frost-prevention at the hands of scientific men. There are many important articles and bulletins on the subject.

The losses occasioned by frost in the citrus and deciduous fruit districts of the United States often reach enormous proportions. It has been impossible to secure accurate information as to what the average annual loss has been over a period of years; but it is safe to say that the loss would approximate $10,000,000 a year. If one takes into consideration the freezes which occurred in the citrus belt in Florida during 1880, 1884, 1886, 1894, and 1895, where not only the fruit but the trees themselves were killed, the loss would average still greater. It is estimated that the freeze of 1894–95 destroyed 3,000,000 boxes of oranges in the Florida groves. Although the citrus industry in California had not yet reached large proportions, the losses were correspondingly heavy. In January, 1913, the losses in the southern California citrus district reached the enormous sum of $50,000,000, all of which might have been saved by means of the present methods of frost-prevention. Deciduous fruits have suffered quite as heavily from frost-injury. Very often almost the entire crop of fruit throughout the eastern and southern states is a complete failure. In the middle West, especially in Colorado, the one great drawback to fruit-growing has been the danger of damage by frost. This has also been true of the deciduous fruit districts of the inter-mountain and Pacific coast states. However, since the advent of the present methods of protecting against frost-injury, much security has been added to deciduous fruit-growing.

The problem of preventing injury to plants from frost may be classified under the following heads:

1. The prediction of frost, and the issuance of adequate frost-warnings.
2. The construction and use of devices and apparatus to be used in frost-prevention.
3. The cost of orchard heating.
4. The physics of orchard-heating.
5. The use of electricity in frost-prevention.

The prediction of frost and issuance of frost-warnings.

The prediction of frost and issuance of adequate frost-warnings necessarily belong to the United States Weather Bureau. It is wholly impossible accurately to predict frost locally without a knowledge of general weather conditions over a considerable area. However, a local observer with a complete knowledge of the climatology of his district and a knowledge of the air-currents, humidity, maximum and minimum temperatures, and the like, is capable of making very accurate forecasts in coöperation with the United States Weather Service. For careful work, a detailed mapping of the climatological features of each district should be made. It is known that temperatures vary greatly within any district, dependent upon elevation, contour, proximity to large bodies of water, and so on.

Frosts usually occur during periods of high barometric pressure, following a period of low pressure in which there has been some precipitation. Under such conditions the air is very dry and dust-free, producing conditions favorable to intense radiation, and consequently causing rapid cooling of both plants and soil.

1587. Orchard-heating with fifty coal-heaters to the acre. Each heater holds from twenty-five to thirty-five pounds of soft coal.

It has been stated more or less empirically that the temperature of the dew-point is a safe guide in the local forecasting of frosts, but recent investigations have shown that it is not dependable when used alone and in disregard of other important factors, such as the daily maximum temperature, temperature-curve, wind-direction, barometer, and condition of the sky. To this should be added a complete knowledge of general weather conditions as obtained from the nearest District Weather Bureau Office.

In 1882, Lieutenant (now Brigadier General) James Allen published a pamphlet entitled "To Foretell Frost by the Determination of the Dew-point." He said that if the dew-point is above freezing in the early evening the minimum temperature next morning will be above freezing; if the dew-point is below freezing, the minimum temperature next morning will also be below freezing. If the prediction of frosts were so simple, anyone with the aid of the psychrometer, or wet-and-dry bulb thermometer, might easily make independent forecasts. However, it has been found that the dew-point is an aid only when used in combination with a perfect knowledge of the other weather factors and a knowledge of the climatology of the district. The dew-point temperature is used in the Rogue River Valley, Oregon, because it has been found a very safe guide in combination with the above factors which were determined by several years of observation and study. From 1909 to 1913 the average departure of the minimum temperature of the following morning from the previous evening's dew-point temperature during periods of spring frosts has been 0.10 F. It is possible that every district, by a careful study of all the factors governing frost conditions, may be able to predict accurately not only the minimum temperature that will occur, but also the time when the firing in the orchards must begin. This is now done in the Rogue River Valley, Oregon, and has been practised for several years without a single error.

The several ways of preventing fall in temperature.

In order to prevent the fall in temperature, the following methods have been practised: (1) Direct heating of the air. (2) Adding water-vapor. (3) Adding both heat and water-vapor. (4) Ventilation or mixing the air. (5) Irrigation, or use of water. (6) Use of heated water and steam. (7) Use of screens or covers to prevent loss of heat by radiation. (8) Spraying with water.

In the discussion of preventing frost-injury, all the methods excepting that of adding heat will be omitted, as recent experiments have shown that direct heating of the stratum of air in contact with the trees and fruits is the only practicable way of handling frost-prevention on a large scale. All the other methods have been given extensive trials, and, while practicable for small gardens, cannot be used over large areas on account of the large amount of labor necessary, and the further fact that their application cannot be made general. Direct heating is not only simple, but is the least costly, and has, therefore, the advantage of general application.

Methods of direct heating in frost-prevention.—As stated above, it has been demonstrated beyond question that adding heat directly to the air through the agency of fires distributed throughout the orchard is the most successful and practicable way to handle the frost problem in commercial orchards. A multitude of devices and many kinds of fuel have been experimented with, and it is now the opinion among growers who have fought frost that the best heat-producing material so far demonstrated is crude-oil or distillate burned in some form of sheet-iron receptacle or smudge-pot. In the first place, oils are easy to handle, may be readily stored, and, compared with other fuels, produce more heat in proportion to the cost. The cost of handling and igniting such fuels as coal and wood, together with the disadvantage of so much bulky material distributed throughout the orchard which interferes with cultivation, decidedly places these fuels at a disadvantage, excepting in very small tracts. No matter how remote a fruit district may be from an oil-field, there is no question but that oil is the best fuel to be used, especially in large commercial orchards when the labor problem is one of more than ordinary importance. There is very much difference in the oils as secured in different parts of the country. For the most part, eastern crude-oils have a paraffine base, while those on the Pacific slope have an asphaltum base. The crude-oil, or petroleum, as it comes from the wells is very rich in gases and the lighter oils, such as benzene, gasolene, kerosene, and others, and, therefore, is not used as such for orchard-heating. The gases and lighter oils are all removed by fractional distillation, leaving behind the heavier oils and the asphaltum or paraffine base, as the case may be. The fuel-oils on the market are, therefore, residuals, and as such are used for orchard-heating. A residual oil with a paraffine base will burn in the common smudge-pot without leaving behind anything but a little soot; but the oils with an asphaltum base do not. For this reason it is found necessary to remove the asphaltum base in so far as is practicable. Asphaltum does not burn readily in a simple smudge-pot, and, therefore, remains behind after the lighter oil has burned. Upon cooling, it becomes very hard, and reduces the capacity of the pot for future fillings. The best oil for orchard-heating purposes is one of approximately 20° Beaumé test, considering the matter of cost as an item. A lighter oil up to 32° Beaumé may be used, but being lighter, it will burn more rapidly and reduce the effective burning time of the orchard-heater.

The orchard-heater.—During recent years, large numbers of types of orchard-heaters have been placed upon the market. As stated elsewhere in this article, the first smudge-pot devised for orchard-heating was the invention of J. P. Bolton, of Fresno, California, and the object of this invention was to produce a device which would effect fairly complete combustion. In fact, the idea in all of the more recent types of orchard-heaters has been to bring about more perfect combustion of the fuel-oil and a consequent reduction in the amount of soot given off. Also, there has been an effort to increase the burning time of the pot by increasing the capacity for fuel-oil. This has been partially effected by several interesting devices, but the perfect pot producing complete combustion of fuel-oil has yet to be invented. The so-called soot-arrester of some types is a misnomer. Very extensive experiments have been made with all the devices on the market, and it has been shown that the plain sheet-iron pot holding approximately five quarts of fuel-oil is just as effective as the more complicated and expensive types. This pot is inexpensive, and when made of No. 29 or 26 sheet-iron will cost from 5 to 8 cents. In using a heater of such small size, the number to the acre should not be less than 100, and preferably more in districts in which periods of low temperature continue more than four or five hours. Owing to the cheapness of such pots, a very large number may be used in preference to using a few expensive heaters of the reservoir type. Many small fires give better results than a few large ones, as the heat is better distributed and convective air-currents are not produced. It must be understood that any orchard-heating device that is in any way complicated by dampers, cocks, valves, and the like, must be avoided. At best, an orchard-heater is roughly handled and the more expensive and complicated types would find a very short existence in actual orchard-heating practice. Furthermore, the matter of storage must be considered. The simple pot which will nest easily and occupy very little space will be more desirable. There is no objection to the high-priced reservoir heater providing it is not complicated, but the same results may be secured by the more simple lard-pail type, holding about five quarts and having a burning time of four and five hours, depending upon the quality of fuel-oil used.

Equipment for orchard-heating.—The equipment absolutely necessary for effective orchard-heating consists of the following:

1. Storage reservoir.
2. Distributing wagon tank.
3. Orchard-heaters.
4. Lighters for igniting the fuel-oil.
5. Thermometers.
6. Frost alarm thermometers.

(1) The storage reservoir should be built of concrete or steel and should have a capacity sufficient to provide for at least five fillings of the orchard-heaters—that is to say, for five frost-periods. Such a reservoir, if built of concrete, should be constructed in such a way as to make the walls and floor one continuous pouring, so as to provide against leakage of oil. Residual oils have no effect upon the concrete, and all leakage is due to improper pouring of the cement. A rich cement mixture should be used. The reservoir should be so placed that it may be filled and emptied by gravity. At best, it is expensive to handle oil, and there should be no pumping. Oil should be secured in tank-car lots, and, if the proper arrangements are made, all the handling may be done by gravity. The reservoir should have an outlet pipe 2½ to 3 inches in diameter and supplied with a close-fitting valve. A cover to keep out dust and rain should also be provided. (2) The supply-tank should be placed upon a heavy low truck and should hold between 300 and 400 gallons. It should be provided either with two heavy gate valves at the rear or with two lines of hose with valves for the purpose of distributing the oil into the orchard-heaters. This tank may be the ordinary supply-tank used to carry spray material. (3) The number of orchard-heaters to be used to the acre will depend upon a knowledge of the conditions under which they are to be used. If the simple one-gallon type of heater is used, at least 100 to 120 should be provided to the acre. Besides, a double row should be placed around the side from which the prevailing air-movement comes in the periods of frosts. In fact, it is best to reinforce all sides of the orchard. After filling the heaters, they should be covered so as to prevent the entrance of moisture or to provide against evaporation of the oil. In placing the heaters, it is best to arrange them somewhere near the intersections of the diagonals made by the trees; but any arrangement which will not place a pot directly under a tree will suffice. (4) Fuel-oil is rather difficult to ignite, and a small amount of gasolene must be used so as to provide for quick lighting. The best method of lighting is to use a machinist's oil-can filled with gasolene, and a torch made of two pieces of thin iron pipe. The larger piece is fitted with a screw cap and is filled with a mixture of kerosene and lard oil. A section of small pipe through which is drawn a piece of waste is then fitted by a reducer to the other end. The waste is kept saturated with the mixture of lard and kerosene and when lighted provides a very good torch. This iron torch is very useful in taking off lids or caps of heaters when lighting. The machinist's oil-can filled with gasolene is carried in the left hand and about two tablespoonfuls are poured on the surface of the fuel-oil in the pots. The torch is applied and the gasolene ignites, firing the heavy fuel-oil. A simpler and lighter torch is easily made by wiring a piece of waste into a ball and twisting the wire into a handle. The waste is kept saturated by plunging it into the oil of the heater, igniting it from the surface flame as it is removed. (5) A most necessary part of any orchard-heating equipment is a sufficient supply of fairly accurate thermometers. There should be at least one thermometer to the acre. The thermometers should be hung with the bulb about 4 to 5 feet from the ground, depending, of course, upon the relative position of the fruiting area of the tree. In many orchards the thermometers will be placed higher, in others, lower. All thermometers should read correctly to within ½°, and if the correction be greater it should be placed upon a tag attached to the thermometer. In reading the thermometers, a pocket electric flashlight is much better than a lantern. The heat from a lantern will cause the mercury to rise before it can be read and the thermometers will, therefore, not give the true atmospheric temperature. The thermometers should be in the open in order to get the approximate temperature of the plants to be protected. This temperature is always slightly lower than the true atmospheric temperature. Besides the thermometers in the orchard, other thermometers placed at a safe distance from the heated area should be provided. A self-registering thermometer, while not necessary as a part of the equipment, would be very useful in determining the actual minimum as well as the rate at which the tem-

perature is falling. (6) The frost-alarm thermometer is a device for sounding an alarm when a certain temperature is reached. This point is usually a degree or two above the danger point, and serves the purpose of giving notice of approaching danger. The thermometer is placed at a point any distance away and where the lowest temperatures usually occur. Wires are led from the thermometer to the house. When the mercury falls below a certain point, the electric circuit is broken and a relay causes a bell to ring. If a thermograph is at hand, the man on duty may easily note by the character of the temperature curve whether or not it may be necessary to prepare for lighting the fires. There are several types of frost-alarm thermometers on the market, but the simplest and most trustworthy of all is the one in which the mercuric column breaks an electric circuit which in turn operates a relay connected with an electric bell.

Besides the above necessary devices for orchard-heating, there have been invented certain automatic devices for lighting a large number of pots at the same time, either by hand or electrical control. Such devices are always complicated, and, disregarding their cost which is an item of considerable importance, they are impractical in large operations. If the means be electrical or mechanical, an expensive cartridge must be used, the cost of which is greater than the cost of the labor for lighting the pots by hand. Besides, all automatic devices require that a large number of wires be strung through the orchard, which would interfere with other orchard practice. As a rule, the period over which frost-injury may occur may be a month or six weeks, and during this time various orchard work must be in progress.

1588. Using wood for orchard heating—fifty fires to the acre.

Injurious temperatures.—The temperatures at which the principal orchard fruits are liable to be injured cannot be accurately stated, since weather conditions previous to a freeze determine to a very great extent the ability of plants to withstand low temperatures. Not only do the different degrees of cold produce different effects on the same plant, but the same plant will often behave differently when subjected to the same degree of cold. It is well known that plants or parts of plants in active growth are more easily killed by low temperatures than the same plants or parts of plants when dormant. Actively growing plants contain large quantities of water; that is to say, the protoplasm or cell-sap is watery, and, as a rule, the larger the proportion of water contained within the plants the more likely they are to be injured by low temperatures. Injury to plants is due to changes or disturbances produced in the protoplasm by low temperatures and, because of the unlike specific characters of different plants, is not always produced in exactly the same way. Some plants are injured at temperatures above freezing, while others are injured by the formation of ice at temperatures which they can withstand if the formation of ice is prevented. Again, some plants are not injured if the formation of ice does not progress too far, while some are resistant to the lowest temperatures. As yet we do not know the nature of the peculiarities which determine the different powers of resistance of individual plants or of the same plant at different stages of growth. It is well known that the resistance to injury can be increased to a certain extent by raising the concentration of the cell-sap. Cold, in itself, acts as a stimulus, inducing an increased production of sugar in many plants. The presence of an increased amount of sugar in a plant acts in such a way as appreciably to lower the freezing-point. While tables giving injurious temperatures to fruit when in bud, blossom, and so on, have been prepared, it is safe to say that these temperatures are not entirely reliable. This is because conditions are never the same in any frost period. It may be stated that in the practice of orchard-heating the safest plan is to keep the temperature just above the freezing-point no matter what the variety of fruit. No doubt, this will often be 2° to 3°, or even more, higher than necessary, but the practice is on the safe side. In orchard-heating practice the temperature should never be allowed to go much below the danger point, as it is usually difficult to bring it back without some chance of injury to the fruit.

Effect of orchard-heating on pollination.—That pollination and subsequent fertilization of the orchard fruits is in any way affected by orchard-heating is yet to be proved. It has been contended by some that the smoke or soot incident to the use of fuel-oil has a tendency to prevent the normal activities of such insects as visit the blossoms of fruit trees. However, there is no proof that the presence of soot on the trees has any effect in keeping insects, especially the honey-bee, away from the newly opened blossoms. Under normal conditions, the blooms which bees visit open during the early part of the day and, therefore, only such blossoms attract them. These blossoms have been closed during the time when smudging was being done, and, therefore, the nectaries, pistils and stamens have no soot deposited upon them. With citrus fruits, soot may have an injurious effect upon the fruit, but it has been found that such fruit may be freed from soot by a washing process which does not materially increase the cost of handling.

The cost of orchard-heating.—The cost of orchard-heating is such a variable quantity that it is almost impossible to make a general estimate which will be of any value. Equipment, cost of fuel, length and number of firing periods, and so on, will vary in different localities and seasons. Orchard-heaters will cost all the way from 6 cents to 50 cents each, and from fifty to two hundred heaters, depending upon conditions, will have to be used to the acre. The quantity of oil will vary with the season, and the cost will be all the way from 1 to 5 or 6 cents a gallon. Usually, no less than 300 gallons an acre should be provided. At least one wagon-tank will have to be provided for each 10 acres at a cost of $25. Lighters and torches will cost from $1 to $2 an acre; thermometers 75 cents to $1 an acre. The cost of a storage-tank charged to each acre will depend upon its size, but will not be far from $10 an acre for large tracts. It is possible to get at the actual cost of fuel-oil to the acre in the following way: The quantity of fuel-oil necessary to raise the temperature 5° F. above the surrounding air in an orchard in full bearing with wide-spreading trees will be approximately twelve and one-half gallons an hour to the acre. This will be true if the air remains calm or does not move more than 1 or 2 miles an hour. In young orchards with the fruiting area low, practically double the quantity of fuel-oil as given will be necessary. The simple lard-pail type of heater, or, for that matter, any type of orchard-heater providing a burning area of about 44 square inches, will burn about one quart of fuel-oil an hour. Fifty one-gallon heaters will burn approximately twelve and one-half gallons of fuel-oil an hour, and if this oil costs 4 cents a gallon, the cost of an acre-hour will be about 50 cents when all the pots are burning. In other words, under the above conditions, it will cost approximately 1 cent an hour for each heater used, providing this heater does not have a burning surface greater than 44 square inches. It will require less fuel to heat an orchard in the square form than one of any other shape. The more the orchard-heaters are massed in the form of a square, the better the results. In fact, it is almost impossible to protect an orchard of only a few rows because there is no massing of the heat generated on account of the lack of braking effect on air-movement.

The physics of orchard-heating.

By common consent, the one-gallon or ten-pound lard-pail type of orchard-heater has been made the standard. This heater has a top diameter of 7½ inches, a bottom diameter of 6¾ inches, and a depth of 8 inches. It has a top burning surface of about 44 square inches, an average burning surface of 40 square inches, and under actual field conditions will hold five quarts. As will readily be seen, the rate of burning fuel-oil will not remain constant owing to the form of the pot. Since the rate of burning does not remain constant, it is natural to suppose that a corresponding change in the orchard temperature-characteristic takes place. In other words, the difference in temperature between the air outside the heated area and that in the heated area does not remain constant. The characteristic for any orchard-heater having sloping sides will be approximately the same as for the standard lard-pail type.

1589. Smudging used to prevent frost-injury.

By repeated experiment it has been shown that the standard lard-pail type heater will burn about two pounds (two pints) of fuel-oil an hour, providing the oil is neither too heavy nor too light gravity. A very simple rule which will determine the burning time of any fuel-oil in the standard pot is to divide the weight of a gallon (in pounds) by two. This will give the number of hours a gallon will burn under actual conditions in the field.

For any other size heater of the lard-pail type, the burning time will vary in accordance with the following law: $K=T\ (DH)^2$, in which T=the time of burning, D=the mean of the top and bottom diameters, and H=the depth, K=a constant. In other words, it has been found that if the mean diameter times the depth be squared and multiplied by the burning time (in hours) of a unit quantity (one gallon) of fuel-oil, the product will be the constant for the same fuel-oil burned under the same conditions, no matter what the size of the pot may be, providing it is not too much out of proportion.

The calorific power of fuels.—Analyses of various fuel-oils on the market have shown that the heating power averages about 18,000 British thermal units to the pound. A pound of dry pine wood, or, for that matter, the best oak wood, if perfectly dry, will generate about 6,000 B. T. U.'s under perfect combustion; bituminous coal under the same conditions will generate 12,000 B.T.U.'s. It will be seen, therefore, that the ratio of wood, coal and fuel-oil is about as 1:2:3. A cord of well-seasoned pine will weigh about 2,000 pounds and that of oak about 4,000 pounds. These figures are, of course, only approximate, but will serve as a basis for calculation in case anyone should desire to use wood or coal for orchard-heating purposes. Since the calorific power of fuel-oil is about 18,000 B.T.U.'s to the pound, the standard fuel-pot burning two pounds of fuel-oil an hour will generate 36,000 B.T.U.'s. This is largely theoretical as, owing to the character of the heater, combustion is by no means perfect. Nevertheless, the amount of oil, as indicated, is consumed, and will, therefore, be accounted for on the basis of complete combustion. By repeated experiment, it has been shown that the quantity of fuel-oil necessary to raise the temperature 5° F. above the surrounding air in an orchard in full bearing with the trees forming a protective covering and the air calm or moving not more than 1 or 2 miles an hour, is approximately twelve and one-half gallons or 100 pounds an hour to the acre. This quantity of fuel-oil is approximately the amount which would be burned in one hour by fifty standard orchard-heaters. In very young orchards, or with a wind of 10 to 15 miles an hour, fully two or three times as much fuel-oil will be necessary to maintain a temperature 5° F. above that of the surrounding air. Under average orchard conditions, with the trees in good bearing, the maximum height at which the bulk of the fruit crop is borne is usually not more than 12 to 15 feet above the surface of the ground. In many cases frost-injury does not occur above this height, the cold-air stratum being relatively thin. During periods of injurious low temperatures, the atmosphere is very dry and, therefore, calculations may be based upon the heating of the air only, since the small amount of water-vapor present at such times is of little importance. Taking an acre as the unit area, and assuming that the height to which the air must be heated to protect the crop is 12 feet, the total weight of the air inclosed within this space would be 42,000 pounds. As stated above, a pound of fuel-oil has a thermal capacity of 18,000 B. T. U.'s, and since it will require 100 pounds of fuel-oil an hour to the acre to maintain the temperature of the air 5° F. above the surrounding atmosphere, 1,800,000 B. T. U.'s or about 700 mechanical horsepower will be expended an hour to the acre on 42,000 pounds of air. But 1,800,000 B. T. U.'s would raise the temperature of 360,000 pounds of water 5° F., and since the specific heat of air is 0.24, it would raise the temperature of

1,500,000 pounds of air 5° F. However, it is seen that 1,800,000 B. T. U.'s are just capable of maintaining 42,000 pounds of air 5° F. above the surrounding atmosphere when there is no wind-movement. This means that even with large trees having the ability of reflecting back a considerable amount of heat, and with the soot and smoke acting more or less as a blanket, the loss by radiation, convection and absorption is enormous. As a matter of fact, $\frac{35}{36}$ of the heat generated by the orchard-heaters is lost, and the efficiency is, therefore, less than 3 per cent. Though effective and well within the financial possibility of application, the orchard-heater is nevertheless a wasteful appliance.

In the above calculations, the effects of wind-movement have not been taken into consideration. Take the case of a pot placed in an outside tree row heating a space 25 feet square and 12 feet high. This space contains in round numbers 600 pounds of air. The standard pot will generate 600 B. T. U.'s a minute, or sufficient heat to raise the temperature of 600 pounds of air about 4° F. This will be true if there is no wind-movement and if there is very little radiation of heat. However, if the air moved only 100 feet a minute, or a little more than 1 mile an hour, the temperature could never rise more than 1° above the temperature of the incoming cold air. At 4 miles an hour it could rise but ¼° F. This will be true only in the outside tree rows, on the side from which the air-movement comes. This shows why it is often difficult to protect the outside rows from frost-injury. Naturally, with the orchard in the form of a square, all the rows beyond the first, on account of air-movement, would receive a certain amount of heat from the first row. However, with a high wind of 18 to 20 miles an hour and a temperature of 10° F. or more below the danger-point, the problem of frost-prevention becomes a serious one. The number of fuel-pots must be three or four times the number required for ordinary orchard-heating.

The value of smoke.—The discussion so far has considered mainly the value of fuels from the standpoint of heating. There is some value in the smoke which is generated but very much less than there is in the heat. When it is calm there is little difficulty in maintaining a heavy smudge with only fifty orchard heaters, or fires, to the acre, but a very light breeze will quickly drive it away. Experience has shown that the smudge is valuable when the temperature drops somewhat below the danger-point about sunrise. In cases of this kind, the smoke acts as a screen and prevents the too sudden warming up or thawing of the frozen fruit. However, it is unsafe to depend on smudge alone.

The use of electricity in frost-prevention.—During recent years much thought has been given the matter of frost-prevention by electrical engineers. However, let it be said that some other means than that of direct electrical heating must be employed. If we take the above figures indicating the amount of heat energy which must be expended to the acre to raise the temperature 5° F. in an orchard and maintain it above that of the surrounding atmosphere, we find that this is equivalent to approximately 700 H. P. of mechanical energy. In the transmission of electrical energy from the source of power, there is always a heavy loss, so that fully 1,000 H. P. of mechanical energy would have to be generated in order to raise the temperature 5° F. in an acre of orchard. From this it will be seen that, although our large electrical power plants are carrying a very light load during the hours of 1 A.M. to 7 A.M., the amount of reserve power would be so small in comparison with the demands that the largest power plant would cover but a very small area. Of course, this consideration takes into account the conversion of mechanical energy into heat energy. In actual practice, the electrical heater is so inefficient that it is wholly beyond the range of possibility for orchard-heating. The problem of frost-prevention by electrical methods must be attacked from a different side, either by the use of high tension discharges or by the use of large electric fans that will tend to stir the air or produce a chimney effect so as to carry the cold air upward. Even the latter will be useless when very low temperatures are accompanied by high winds.

A simple method of estimating the quantity of fuel necessary to raise the temperature of the air in an acre of orchard any number of degrees Fahrenheit under every condition is as follows: In a full bearing orchard there are approximately 500,000 cubic feet of air to the acre which must be heated continuously, it being considered that the height to which heat must be added is about 12 feet. By experiment, it has been shown that it will require about 0.75 to 1.00 B. T. U. to the cubic foot an hour to maintain the temperature 1° F. above that of the surrounding atmosphere. Therefore, it will require 375,000 to 500,000 B. T. U.'s an hour, under average conditions to maintain the temperature of an acre of orchard 1° F. above that of the surrounding atmosphere. Since one pound of crude-oil or distillate contains approximately 18,000 B. T. U.'s, the number of pounds of fuel-oil required to the acre-hour will be twenty to twenty-eight pounds. Since a pound of oil is approximately one pint, the quantity of oil an acre-hour for 1° F. rise will be two and one-half to three and one-half gallons. As shown above, the ratio of wood, coal and oil is about as 1:2:3, wood having 6,000, coal 12,000, and oil 18,000 B. T. U.'s to the pound.

S. Weather Bureau.

P. J. O'Gara.

FRUIT-GROWING comprises all the knowledge and practice that are directly concerned in the producing and handling of fruits. Pomology (literally, *science of fruits*) is synonymous with fruit-growing. There has been an effort to divorce the terms pomology and fruit-growing, making the former to comprise the scientific and classificatory subjects and the latter the practical subjects; but such division is arbitrary and is opposed to usage. The word "growing" can no longer be held, when used in such connection, to designate merely the planting and care of fruit-plants, for all good practice is necessarily associated with scientific knowledge and theory. Fruit-growing is a more familiar and homely term than the Latin-Greek word pomology, and for that reason it has seemed to some persons to be less adaptable to the formal presentation of the knowledge connected with fruits. It is significant, however, that with the exception of Prince's "Pomological Manual," the fruit books that have done much to mold public opinion in America have not been known as pomologies, notwithstanding the fact that the greater number of them have given great attention to formal descriptions of varieties. The term pomology is founded on the Latin *pomum*, a word that was used generically for "fruit." In later Latin it came to be associated more particularly with the apple-like fruits. The word is preserved to us in the French *pomme*, meaning "apple," and in other languages of Latin derivation. In English we know it as *pome*, a botanical term used to designate fruits that have the peculiar morphological structure of the apple and pear. This use of the term is explained under the article *Pyrus*. However, the root of the word pomology is derived from the Latin *pomum* rather than from the botanical *pome*.

The limitations of fruit-growing, as art and discussion, depend on the use of the word "fruit." This word, as used by the horticulturist, is impossible of definition. Products that are classed with fruits in one country may be classed with vegetables in another. To the horticulturist a fruit is a product that is closely associated, in its origin, with the flower. As used in this country, it is the product of a bush or tree or woody vine, the most marked exception being the strawberry. Most fruits may be grouped under three general heads, —orchard or tree fruits, vine fruits (of which the grape is the type), and small-fruits or "berries." Of the orchard fruits, the leading groups are the pome-fruits (apple, pear), drupe-fruits (peach, plum, cherry), and the citrus-fruits (orange, lemon). Of the small-fruits, we may distinguish the bush-fruits (raspberry, blackberry, currant, gooseberry, blueberry), cranberry, and the strawberry. There are many fruits, particularly in the tropics, that do not fall within these groups. The species of fruits that are fairly well known in North America are not less than 150, but the important commercial species are not more than forty.

1590. A vineyard of American grapes (New York). Picking-crates are shown in the foreground.

Fruit-growing is the most important and characteristic horticultural interest of North America. It is of high excellence as measured by commercial standards, quantity of product, and the quickness with which scientific theory and discovery are applied to it. Most remarkable examples of the quick assimilation and application of theoretical teachings are afforded by the readiness with which fruit-growers within recent years have adopted the ideas associated with tillage, spraying, pollination, fertilizing, pruning, inter-planting, and the modifications in conditions of marketing. Yet, great as have been the advances, progress has only begun; and in the precise and painstaking application of the best teaching the American fruit-grower has much to acquire.

The American ideals in fruit-growing are quite unlike the European. The American aims at uniformity over large areas. The European gives more attention to special practices, particularly in training of fruit trees. This is well illustrated in American nurseries as contrasted with European nurseries (see *Nursery*). The American merely prunes his fruit trees in the nursery: he does not train them. The American is likely to give most attention to the fruit by the bushel or by the barrel; the European is likely to consider his fruits singly or in small numbers, and often to sell them by the piece or by the dozen.

In many parts of North America, the extension of fruit-growing is the most radical change of base taking place in farming operations. This growth of the fruit business is possible because the consumption of fruit is increasing, the facilities for transportation have been improved, scientific discovery has insured the production of good crops, and also because many other kinds of farming have been relatively unprofitable.

While the phenomenal development of American fruit-growing has been due in great measure to climatic and economic conditions, it also has been hastened by book writings. More than fifty authors have contributed books of greater or less size, either on the general subject or on special fruits, beginning with Coxe's "View of the Cultivation of Fruit Trees" in 1817, and followed by Thacher's "American Orchardist" in 1822. These pioneer writings gave much of their space to orchard management, with little mere compilation of descriptions of varieties. Subsequent volumes, for nearly fifty years, were in large part compilations and collations of accounts of varieties. To this latter class belong the works of Prince, Kenrick, Downing, Thomas, Warder. It is only in the present time that we have come to treat the subject fundamentally, by giving the weight of discussion to principles of orchard management. (For lists of books, see the article *Literature*.) In recent years, the bulletins of the United States Department of Agriculture and of the many experiment stations, and the extensive discussion in the rural press, have greatly spread the knowledge of fruit-growing and have undoubtedly stimulated its practice.

The sources of American fruits—of the species and races that are cultivated on this continent—are chiefly four: (1) Original or early importations of western Asian and European fruits; (2) oriental types, from the China-Japanese region; (3) the introduction within fifty years of fruits from the Russian region; (4) the development of native species. In the first group are included the prevailing types of apples, pears, quinces, cherries, domestica plums, olives, currants, some of the gooseberries. In the second group are citrous fruits, peaches, apricots, Japanese plums, kaki, and others, many of them having come to us by way of Europe. In the third class—the Russian fruits—are types of orchard fruits of such recent introduction that we have only recently ceased disputing violently about their merits and demerits; therefore a special review of the subject is given at the close of this article. The fourth class—the native fruits—includes the grapes of the eastern states, blackberries, dewberries, raspberries, many gooseberries, strawberries (of Chilean origin), many plums, cranberries, blueberries, and a few apples.

Recently, there has been much interest in fruit-growing on the part of persons who desire to establish themselves on the land. The attractiveness of fruit appeals to them, and they think that the raising of it is not laborious and that the business is adaptable to beginners. This is one expression of amateurism. Fruit-growing entails continuous, active and often hard, disagreeable labor, and, in the case of most orchard fruits, it requires long waiting for perfect results. The business demands much special knowledge, quick action, and first-rate salesmanship. The competition is sharp. Persons should enter the business with caution, and only with a full comprehension of the elements of failure and success. The business has additional risk when one must leave the property to be managed and cared for by hired labor. Usually, the most profitable results are secured when part of the farm is devoted to other products than fruit, for one is then able to employ help and equipment more advantageously, to raise produce for the teams and other live-stock, and to have secondary sources of revenue.

In North America, it is chiefly the commercial large-area fruit-growing that is most highly developed. The amateur phase,—for fancy and for home use,—was once relatively more important, as explained in a subsequent paragraph. The "fruit garden" is now little seen. It is very desirable, however, that the growing of the choicest fruits in the most painstaking personal way shall be encouraged amongst us; and with the further development of the country this will take place if writers do not overlook the subject.

In Canada, the total yields of fruits for thirty years have been as follows, in quantities (Canada Yearbook, 1910):

Canada	1871	1881	1891	1901
Apples (bushels).	6,365,315	13,377,655	7,519,913	18,626,186
Peaches (bus.)...	......	......	43,637	545,415
Pears (bushels)...	......	......	229,240	531,837
Plums (bushels).	......	......	266,350	557,875
Cherries(bus.)...	......	......	192,369	336,751
Otherfruits(bus.).	358,963	841,219	320,641	70,396
Grapes (pounds).	1,126,402	3,896,508	12,252,331	24,302,634
Small-fruits (qts.)	......	......	......	21,707,791

The exports of fruits from Canada to all countries has been as follows:

	1906	1908	1909	1910
Apples, green or ripe (barrels)..	1,217,564	1,629,130	1,092,066	1,604,477
Apples, dried (lbs)	3,651,260	6,939,088	4,973,562	8,186,984

Of the green apples, the most part went to Great Britain, but the dried fruit went largely to other countries than Great Britain or the United States. Ontario was far in the lead of any other province in fruit-production in 1901, in grapes, small-fruits and apples exceeding all the other provinces combined.

In the United States, the value of fruits (including small-fruits or berries) and nuts produced in 1909 (as reported in the thirteenth census) amounted to $222,024,000, or 4 per cent of the total value of farm crops. The value reported for 1899 was $133,049,000, the increase for the decade amounting to 66.9 per cent. While it is impossible to reduce the quantity of the product to a single total, the statistics for individual classes show that in general the value increased by a much larger percentage than the production. Of the total value in 1909 of fruits and nuts, $140,867,000 was contributed by orchard fruits, $29,974,000 by small-fruits, $22,711,000 by citrous-fruits, $22,028,000 by grapes, $4,448,000 by nuts, and $1,995,000 by tropical and sub-tropical fruits (other than citrous). In both acreage and quantities, strawberries far exceeded any other class of small-fruits; similarly, apples are far in excess of any other orchard fruit; oranges far exceed in value all other citrous-fruits taken together. In nuts, the production in pounds in 1909 was, Persian or English walnuts 22,026,524; black walnuts 15,628,776; pecans, 9,890,769; almonds, 6,793,539; unclassified, 7,988,402. The values of fruits and nuts in 1909, by states, are displayed in Fig. 1593.

The progress in fruit-growing.

The development of American fruit-growing is well illustrated in the radical change of ideals within recent time. These new points of view may be arranged conveniently under seven general heads:

(1) The most important shift is the fact that there is a horticultural industry as distinguished from a general agricultural industry. At the opening of the nineteenth century American agriculture was more or less homogeneous, largely because the extent of it was limited and because there was little demand for other than the few staple commodities. The horticulture of that time was confined chiefly to a small area about the homestead. A few vegetables, flowers and fruits in a small plantation, with here and there a single greenhouse, represented the horticultural effort of the time. At the present day we conceive of great geographical areas as horticultural regions. Persons now buy farms with the explicit purpose of devoting them to the production of fruits or other horticultural products. Even sixty years ago horticulture was largely an amateur's avocation, but today it is one of the leading commercial occupations of the country, and the most important single factor in it is fruit-growing. With this rise of the horticultural industries came a demand for new knowledge on a host of subjects which were unheard of even as late as a half-century ago. The contemporary progress in pomology is largely a breaking away from the old ideals. Practices that were good enough for amateur purposes, or for the incidental and accidental fruit-growing of our fathers, may be wholly inadequate to the new-time conditions.

1591. Young plum orchard, showing clean tillage and high-heading.

Some growers head-in vigorous young trees like the above; others prefer to let them take their natural course, keeping the heads open rather than thick and close. Neither method is best under all circumstances.

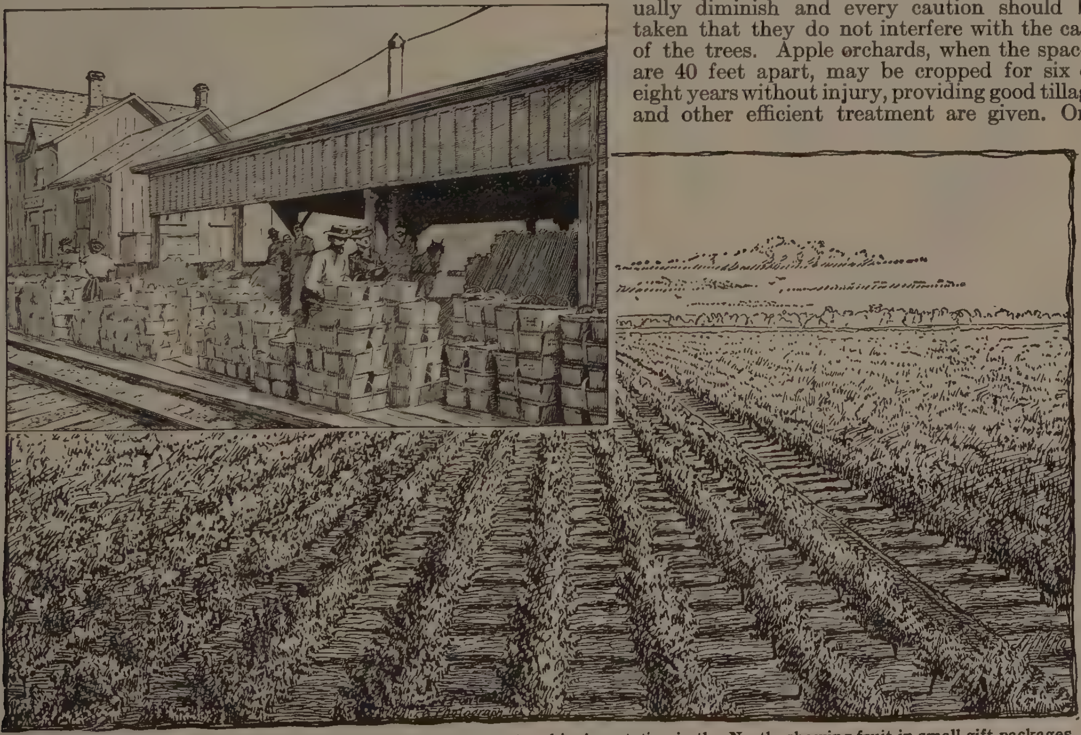
A century ago there was practically no commercial orcharding. The apple was grown somewhat extensively in many parts of the country, particularly in New England, but it was used chiefly for the making of cider. Small-fruit growing, as a business, had not developed. In fact, commercial strawberry-growing (the most readily developed of the fruit-growing industries) may be said to have begun with the introduction of the Hovey in 1836, although previously there were market plantations of small extent about some of the larger towns. The commercial culture of blackberries and raspberries, although it began about the middle of the century, did not acquire distinct importance until after the reaction from the Civil War. The fruit-growing industries now constitute a distinct branch or department of our agricultural condition, in the newer regions as well as in the old. In fact, great areas of virgin lands are now put at once into orchards.

(2) With the rise of commercial fruit-growing, there have developed novel questions related to marketing. The new marketing revolves about three centers: (*a*) The necessity for special products for special uses, (*b*) the growing demand for small packages, and (*c*) the remarkable development of transportation facilities and of pre-cooling, handling, and storage. There has arisen an increased desire for special grades and for particular kinds of fruit. The fruits that were current fifty years ago may not be good enough for the markets of today. Commercial fruit-growing rests on the fact that more persons are consuming fruits. Many of these persons buy only in small lots for present consumption. They go to the market often. They have no facilities for storing the fruit, and they do not buy for the purpose of selling. Therefore, the small package has come to be increasingly more important. There has been a

widespread demand for a package that can be given away with the fruit. This demand for the small and individual package may be expected to increase with all the better kinds of fruits or with those that appeal to the personal customer. This is true in all lines of trade. Not so long ago, boots and shoes were distributed in large board cases, but now each pair is sold in a neat cardboard box. We are still conservative in respect to the handling of apples in barrels. In the general trade and for the staple varieties of apples, the barrel may continue to be the best package, but for the personal customer and particularly with all the finer or dessert varieties, a small package must come into use. In most parts of the world, except in the central and eastern part of the United States, apples are not handled in barrels. The fact that the grower must give attention to his package as well as to the growing of his crop, forces him to adopt a new point of view in his fruit-growing and to visualize his market or even his customer.

(3) Modern commercial orcharding has developed the tillage ideal. Under the old régime, the tree was able to take care of itself and to bear a product good enough to meet the uncritical demands. Nowadays, however, the tree must receive the very best of care, for annual crops of great quantity and of the best quality are desired. Therefore, the plant must be supplied with abundance of plant-food and moisture. Time was when it was thought that the mere application of chemical plant-food to the soil would be sufficient to make a plant productive. It is now understood, however, that plant-food is only one of the requisites of good growth. The soil must be deep and loose and fine, so that it will hold moisture and promote all those chemical and biological activities that make the land to be productive. In former times the best attention in tillage was given to the annual crops. The orchard was usually in neglect. This was because the fruit plantation had small commercial importance. Now that the fruit plantation has risen to first importance, in many cases, it must be given as good care as any farm crop. In recent years there has been great development of special tools and implements for the tillage of orchard lands. Greater attention is given to the original preparation of the land, so that planters no longer ask how large the hole must be to receive a tree, but accept Warder's advice that the hole should be as large as the orchard. The philosophy of orchard tillage, as understood by the best teachers and for most parts of the country, is (*a*) to prepare the land thoroughly at the outset, (*b*) to give frequent light surface tillage in the early part of the season or until the crop is nearly or quite grown, and then (*c*) to cover the land with some crop that will remain on the ground over winter and be plowed under in spring. If the land has been well prepared, it is not necessary to plow it deep after the first two or three years, unless one is turning under a heavy cover-crop. The surface tilth may be secured by breaking the top-soil early in spring with a cutaway harrow, gang-plow or other surface-working tools. This may not be possible, however, on very heavy lands. The cover-crop adds humus and protects the land from puddling and baking in the winter. If it is a leguminous crop it also adds a store of available nitrogen. It is possible, perhaps, to use cover-crops so freely that the land becomes too full of vegetable matter, but all such dangers are easily avoidable. Usually the cover-crop is plowed under in spring at the very earliest opportunity in order to save the soil moisture. It is by no means the universal practice to use cover-crops on fruit lands, but the practice is now accepted, and the grower may adopt it or not as his judgment dictates.

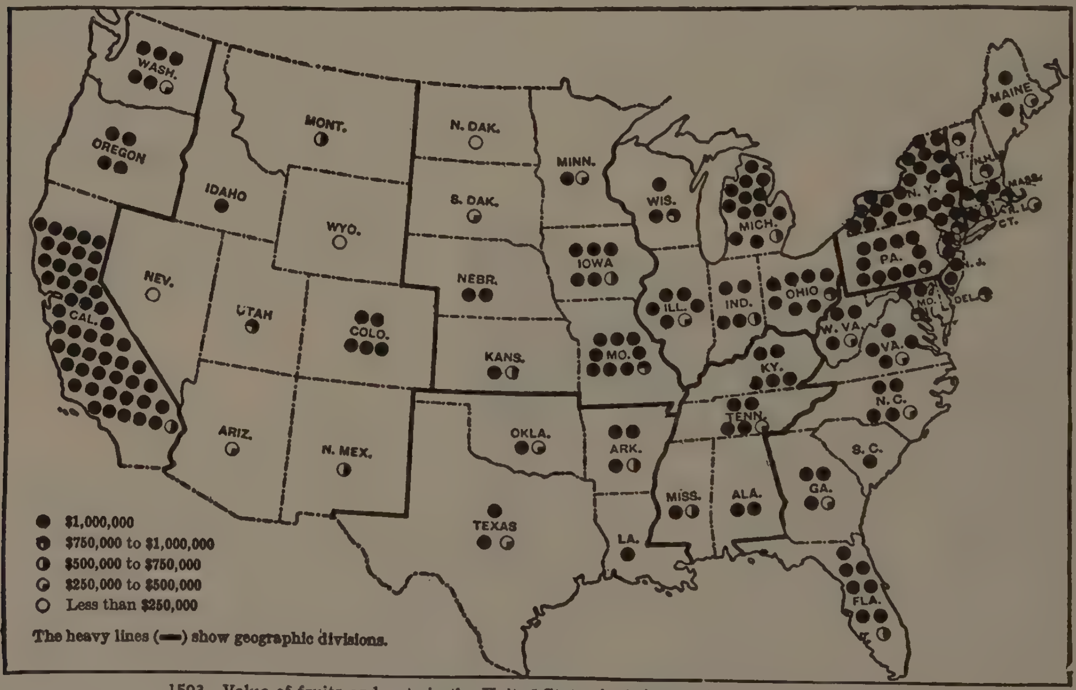
To facilitate the economical and efficient tillage of fruit lands, it is coming to be the practice to devote the land wholly to the fruits. The fertility of the land is not permanently divided between trees and hay, or trees and other crops. With plums and pears and some other orchard fruits, it is often allowable to use the intermediate land for the first two or three years for annual crops, but these crops should gradually diminish and every caution should be taken that they do not interfere with the care of the trees. Apple orchards, when the spaces are 40 feet apart, may be cropped for six or eight years without injury, providing good tillage and other efficient treatment are given. One



1592. Peach-growing on a large scale in Georgia; also a scene at a shipping-station in the North, showing fruit in small gift packages.

reason for allowing orchards to stand in sod in the old times was the difficulty in plowing beneath full-grown trees. Those persons who desired to plow and till their orchards, therefore, advocated very high pruning. The difficulty with these old orchards was the fact that the land was allowed to run into dense sod. Heavy plowing in an old orchard indicates that the plantation has been neglected in previous years. Orchards that have been well tilled from the first do not require much laborious tillage, and the roots are low enough to escape tillage tools. There has been a development of tillage tools which will do the work without necessity of pruning the tops very high. The practice of tilling orchards has increased rapidly. At first it was advised by a few growers and teachers, but the movement is now so well established that it will take care of itself, and in the commercial orchards the man who does not till his orchard is the one who needs to explain. On the Pacific coast, the importance of tillage is universally recognized because of the dry summer climate. The necessity of tilling orchards has forced a new ideal on the pomologist; and when he goes to the expense of tilling he feels the necessity of giving sufficient care in other directions to insure profitable returns from his plantation. It is true, to be sure, that orchards sometimes thrive under sod treatment, but these are special cases.

Of the same purpose with tillage is irrigation,—the purpose to fit the land for its work. Great fruit regions in the western half of the continent are on an irrigation basis and a special literature on fruit-raising under such conditions is now appearing. This irrigation practice for fruit is another expression of the idea that in the future nothing is to be left to chance so far as it is within the power of the grower to prevent it. For certain intensive fruit-culture, particularly of berries, special irrigation practices are appearing in the East, and often they make the difference between failure and success.



1593. Value of fruits and nuts in the United States in 1909, as displayed by the census.

(4) As competition increases, it is necessary to give better attention to pruning. It is unfortunately true that trees will bear without pruning. This, therefore, puts a premium on neglect. The old practice allowed the tree to grow at will for three or four years and to become so full of brush that the fruit could not be well harvested, and then the top was pruned violently. The tree was set into redundant growth and was filled with water-sprouts. This tended also to set the tree into wood-bearing rather than into fruit-bearing. By the time the tree had again begun fruit-bearing, the orchardist went at it with ax and saw and a good part of the top was taken away. It is now understood that the ideal pruning is that which prunes a little every year and keeps the tree in a uniformly healthy and productive condition. The pruning of trees has now come to be a distinct purpose, and this ideal must gain in definiteness and precision so long as fruit trees are grown. The practice proceeds on established principles, and is not of the nature of discipline.

(5) Now that there is demand for the very best products, it is increasingly important that fruits be thinned. The thinning allows the remaining fruits to grow larger and better, it saves the vitality of the tree, and it gives the orchardist an opportunity to remove the diseased specimens and thereby to contribute something toward checking the spread of insects and fungi. Thinning is exceedingly important in all fruits that are essentially luxuries, as peaches, apricots and pears. It is coming also to be important for apples and for others of the cheaper fruits. In the thinning of fruits, there are two rules to be kept in mind: (*a*) Remove the injured, imperfect or diseased specimens; (*b*) remove sufficient fruit so that the remaining specimens stand at a given distance from each other. How far apart the fruit shall be, depends on many conditions. With peaches it is a good rule not to allow them to hang closer than 4 or 5 inches (sometimes 7 or 8 inches), and in years of heavy crops they may be thinned more than this. This extent of thinning often removes two-thirds of the fruits. It nearly always gives a larger bulk of fruit, which brings a higher price. Thinning is

usually performed very early in the season, before the vitality of the tree has been taxed, and after the normal "drop" from non-pollination has occurred.

1594. Various spraying rigs. 1. A tall platform rig, to enable one to spray very high trees. 2. A simple barrel outfit for small orchards and small trees. 3. Compressed air outfit. 4. A low rig, with barrel. For larger machines, and other patterns, see pages 1058–1060 (Vol. II).

(6) Spraying of fruit plantations has now come to be a definite purpose and an established orchard practice; no good orchardist is now without his spraying apparatus any more than he is without his tillage tools. When spraying was first advised, the practice seemed to be so revolutionary that great emphasis had to be laid on its importance to induce people to undertake it. How and when to spray and what materials to use are matters that will always be discussed, because the practices must vary with the season, the kind of fruit, the geographical region, the insects and fungi to be combated. Spraying may not be necessary every year, and certainly not equally necessary in all geographical regions; but the fact that spraying is necessary as a general orchard practice is now completely established. A proof of the firm hold that spraying has taken of the fruit-growing business is afforded by the great numbers and the mechanical excellence of the machinery and devices now on the market; and this fact also attests the vitality of fruit-growing as an occupation. A special literature has developed on fruit diseases and fruit insects and the means of combating them, and the grower must keep fully informed by means of the government, state and provincial publications.

(7) Perhaps the most gratifying modern development in fruit-growing is the demand for instruction in fundamental principles, or in the reasons why. Years ago, the grower was satisfied if he had definite directions as to how to perform certain labor. He was told what to do. At present, the pomologist wants to be told what to think. There seems to be a tendency in horticultural meetings to drop the discussion of the mere details of practice and to give increasingly more attention to the underlying reasons and the results that are to be expected from any line of practice. Knowing why a practice should be undertaken and what the results are likely to be, the grower can work out the details for himself, for every fruit plantation and every farm is, in a certain way, a law unto itself. There must be a rational procedure; the details and the applications are complex: therefore the fruit-growing subjects become effective means of education.

Systematic pomology.

The classifying and describing of the kinds of fruits is a particular kind of pomological knowledge that is left to specialists, who are for the most part writers. With the increase in numbers of varieties, it becomes increasingly more important that the most careful attention be given to describing them and to assembling them into their natural groups in order that similar kinds may be compared and also that it may be possible to determine the name by analyzing the specimen. Necessarily, all classificatory schemes for varieties are imperfect since the varieties often differ by very slight characters, and these characters may vary in different regions and under varying conditions. Theoretically, the most perfect classification is one that considers characters of flowers as well as of fruits, but such schemes are usually impracticable because fruit-growers cannot secure flowers and fruits at the same time. For examples of classificatory schemes the reader may consult the various fruit manuals, but the following examples from the older literature will show something of the range and method connected with the problem:

John J. Thomas' scheme for classifying peaches:

Division I. Freestones or Melters.
 Class I. *Flesh pale or light-colored.*
  Section 1. Leaves serrated, without glands.
  Section 2. Leaves crenate, with globose glands.
  Section 3. Leaves with reniform glands.
 Class II. *Flesh deep yellow.*
  Section 1. Leaves crenated, with globose glands.
  Section 2. Leaves with reniform glands.
Division II. Clingstones or Pavies.
 Class I. *Flesh pale or light-colored.*
  Section 1. Leaves serrated, without glands.
  Section 2. Leaves crenate, with globose glands.
  Section 3. Leaves with reniform glands.
 Class II. *Flesh deep yellow.*
  Section 1. Leaves serrate, without glands.
  Section 2. Leaves with reniform glands.
 Class III. *Flesh purplish crimson.*
  Section 1. Glands reniform.

Following is John A. Warder's scheme for classifying apples, adopted "after a long and careful consideration and study of this subject." See Figs. 1595, 1596.

Class I. *Oblate or flat,* having the axis shorter than the transverse diameter.
 Order I. *Regular.*
 Order II. *Irregular.*
  Section 1. Sweet.
  Section 2. Sour.
   Subsection 1. Pale or blushed, more or less, but self-colored and not striped.
   Subsection 2. Striped or splashed.
   Subsection 3. Russeted.
Class II. *Conical,* tapering decidedly toward the eye, and becoming *ovate* when larger in the middle and tapering to each end, the axial diameter being the shorter.
 Orders I and II, as above.
  Sections 1 and 2. as above.
   Subsections 1, 2 and 3, as above.
Class III. *Round, globular* or nearly so, having the axial and transverse diameters about equal, the former often shorter by less than one-quarter of the latter. The ends are often so flattened as to look truncated, when the fruit appears to be cylindrical or globular-oblate.
 Orders, Sections and Subsections as above.
Class IV. *Oblong,* in which the axis is longer than the transverse diameter, or appears so. These may also be truncate or cylindrical.
 Orders, Sections and Subsections as above.

Robert Hogg's classification of pears ("Fruit Manual," 5th ed., London):

A. The length from the base of the stalk to the base of the cells greater than from the base of the cells to the base of the eye.
 Section 1. Length from the base of the stalk to the base of the eye greater than the lateral diameter.
 Section 2. Length from the base of the stalk to the base of the eye less than the lateral diameter.
 Section 3. Length from the base of the stalk of the base of the eye equal to the lateral diameter.
B. The length from the base of the stalk to the base of the cells less than from the base of the cells to the base of the eye.
 Section 1. Length from the base of the stalk to the base of the eye greater than the lateral diameter.
 Section 2. Length from the base of the stalk to the base of the eye less than the lateral diameter.
 Section 3. Length from the base of the stalk to the base of the eye equal to the lateral diameter.

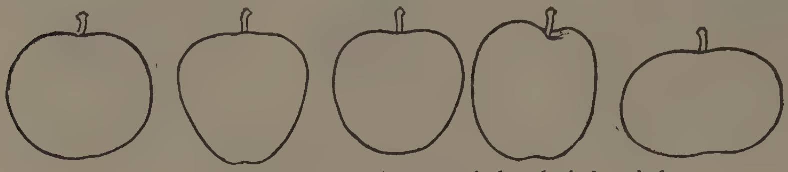
c. The length from the base of the stalk to the base of the cells equal to that from the base of the cells to the base of the eye.

Section 1. Length from the base of the stalk to the base of the eye greater than the lateral diameter.

Section 2. Length from the base of the stalk to the base of the eye less than the lateral diameter.

Section 3. Length from the base of the stalk to the base of the eye equal to the lateral diameter.

A stable and attractive systematic pomology must give careful attention to the names of varieties. In North America much has been done, particularly under the auspices of the American Pomological Society, to simplify and codify the ideas associated with the nomenclature of fruits. The current rules or code of nomenclature of the American Pomological Society are as follows:



1595. The forms of fruits, showing, respectively, spherical, conical, ovate, oblong and oblate forms.

Priority.

Rule 1. No two varieties of the same kind of fruit shall bear the same name. The name first published for a variety shall be the accepted and recognized name, except in cases where it has been applied in violation of this code.

(*a*) The term "kind," as herein used, shall be understood to apply to those general classes of fruits which are grouped together in common usage without regard to their exact botanical relationship; as, apple, cherry, grape, peach, plum, raspberry, etc.

(*b*) The paramount right of the originator, discoverer, or introducer of a new variety to name it, within the limitations of this code, is recognized and emphasized.

(*c*) Where a variety name through long usage has become thoroughly established in American pomological literature for two or more varieties, it should not be displaced nor radically modified for either sort, except in cases where a well-known synonym can be advanced to the position of leading name. The several varieties bearing identical names should be distinguished by adding the name of the author who first described each sort, or by adding some other suitable distinguishing term that will insure their identity in catalogues or discussions.

(*d*) Existing American names of varieties which conflict with earlier published foreign names of the same, or other varieties, but which have become thoroughly established through long usage, shall not be displaced.

Form of names.

Rule 2. The name of a variety of fruit shall consist of a single word, whenever possible, or compatible with the most efficient service to pomology. Under no circumstances shall more than two words be used. When the exigencies of a case make it appear expedient, such words as early, late, white, red, and similar ones may be used as a part of a name.

(*a*) No variety shall be named unless distinctly superior to existing varieties in some important characteristic nor until it has been determined to perpetuate it by bud-propagation.

(*b*) In selecting names for varieties the following points should be emphasized: distinctiveness, simplicity, ease of pronunciation and spelling, indication of origin or parentage.

(*c*) The spelling and pronunciation of a varietal name derived from a personal or geographical name should be governed by the rules that control the spelling and pronunication of the name from which it was derived.

There are relatively few special technical terms used in the descriptions of pomological fruits. The greater part of them pertain to the pome fruits. The diagrams (Figs. 1595, 1596) illustrate some of these terms: *Spherical*, nearly or quite globular, the two diameters being approximately equal; *conical*, longitudinal diameter equaling or exceeding the transverse diameter, and the shoulders or apex somewhat narrowed; *ovate*, broad-conical, the base more rounded; *oblong*, longitudinal diameter distinctly the longer, but the fruit not tapering; *oblate*, distinctly flattened on the ends. In the true Japanese or sand pears, the fruit is usually apple-form. In Fig. 1596 are shown special parts of the fruit: *basin*, the depression at the apex, in which is the *calyx* or *eye; cavity*, the depression at the base, in which is the *stem* or *stalk; suture*, or the groove on the side of plums and other fruits; *corrugated* or *furrowed* sides. The outline shape of an apple or pear is best seen by cutting the fruit in halves lengthwise; the flat side may then be used to print the form on paper.

If descriptions are to be accurate and comparable, they should characterize all the leading or designative attributes of the fruit, and to a less extent of the plant as a whole. Many persons who are called on to describe varieties have adopted "forms" or regular outlines, in order that all characterizations in any one fruit shall be comparable. The following forms, adopted by the late John Craig, illustrate the points that a good description should cover:

Name... ....

1596. Illustrating special terms used in describing fruits, showing, respectively, basin, cavity, suture, corrugation.

At present, the scoring or judging by points is a favorite exercise in classroom and at exhibitions. The score-card with points or attributes totaling 100 indicates the perfect fruit: the judge puts against the perfect score such percentage of perfection as he thinks the specimen in hand may deserve. This judgment of course varies with the person, as the marks are not mathematical; but experienced judges make very similar or uniform returns on given specimens.

Following are examples of score-cards:

SCALE OF POINTS FOR JUDGING FRUITS.

Established by the Massachusetts State Board of Agriculture.

	No. of points	Score
Quality	20

L. H. B.

Russian fruits.

The Russian apples and their close relatives, the Siberian crabs and their hybrids, constitute the hardiest types of pomaceous fruits in cultivation. It was the demand for hardy varieties for the northwestern states and Canada that led to their introduction.

1597. Longfield, one of the Russian apples. (×⅓)

There are four varieties of Russian apples that may be looked on as American pioneers; these are Alexander, Tetofsky, Duchess (Borovitsky) and Red Astrachan. These varieties were imported by the Massachusetts Horticultural Society from the London (England) Horticultural Society about 1835. They were brought to England from Russia in the early part of the last century by the executive of the latter society. Dr. Hogg is authority for the statement that Alexander was cultivated for 50 years in England prior to 1808. Robert Manning, superintendent of the test garden of the Massachusetts Horticultural Society at Salem, described these varieties from home-grown American specimens in 1839. Their productiveness and the handsome appearance of the fruit attracted attention. Through the efforts of Warder and other western pomologists they were rapidly distributed throughout Ohio, Wisconsin and Minnesota. It would appear that in the last half- or three-fourths-century—which practically covers the pomological history of the West—the periodicity of "hard" or "test" winters has been more or less regular. When the normal or "mild" winter obtains, the apples of the New England states or their descendants do not, as a rule, suffer injury except in the colder parts of Minnesota. These mild winters have followed each other with delusive regularity for periods of ten, fifteen or eighteen years. Under these conditions, fruit-growers have been prone to efface from their memories the effects of the last "test winter" and have planted freely of the American type. With this type have been usually mingled Alexander, Oldenburg and Red Astrachan. It has been invariably noted that after the visitation of an exceptionally cold winter varieties of the Oldenburg or Alexander types were usually unharmed, while Greening, Janet, and Baldwin were killed. "Test winters"—the name has more or less local adaptation in the West—visited the northwestern states in 1855–6, 1872–3, 1885–6, and also in 1898–9. Thus it is that Oldenburg (Duchess) has become a standard of hardiness among apples in the colder parts of the United States and Canada. Importations of cions were made by nurserymen and fruit-growers between 1867 and 1875, but the main introduction was made by the United States Department of Agriculture in 1870 at the urgent request of the State Agricultural Society of Minnesota, which began the agitation as early as 1867. This importation consisted of young trees secured through the coöperation of Edward Regel, director of the Imperial Botanic Gardens at St. Petersburg. The trees were planted on the grounds of the Agricultural Department at Washington. The collection consisted of about 300 varieties. They were taken charge of by William Saunders, superintendent of gardens and grounds. All available cions were cut and distributed annually for five years. They attracted considerable attention in the colder apple-growing regions. Subsequent importations of cions and trees were made by the Iowa Agricultural College between 1875 and 1880. In 1882 Charles Gibb, of Abbotsford, Canada, accompanied by J. L. Budd, of the Iowa Agricultural College, went to Russia and spent the summer in investigating these fruits. Large importations of apples, plums, pears and cherries followed. In these later importations the east-European fruits were collected without discrimination, and in most instances have been erroneously regarded in this country as authentic Russians.

Russian apples: characteristics and nomenclature.

It is now very difficult to say which are Russian apples, which German, Polish or Swedish. If we were to choose the Astrachan variety as a type of the Russian apple, which in all probability would be a correct basis, only a comparatively small number of varieties could be grouped about it. But this is only one of the several apparently authentic groups which might be erected upon certain characteristics of tree. In addition to Astrachan might be cited (1) Hibernal type: trees vigorous growers, with open spreading tops, and very large, leathery leaves. (2) Oldenburg type: moderate growers, with compact, round-topped heads; leaves of medium size. (3) Longfield type: slow growers; branches horizontal or pendulous; leaves whitish and woolly underneath. The Longfield apple, one of the best known of the Russians, is shown in Fig. 1597. (4) Transparent and Tetofsky type: trees pyramidal; bark yellow; spurs numerous; leaves large, light green. (5) Anis type: trees upright, spreading or vase-shaped; leaves medium, veins reddish. It would seem reasonable to suppose that the Anis family was derived from the Astrachan type. The flesh of the fruit of the various types is very similar.

These represent the principal types of Russian apples. The fruit they bear in the prairie climate matures in the summer, autumn or early winter. It does not appear that any of the especially hardy varieties of undoubted north or east Russia origin are winter kinds when grown in the Mississippi Valley. Such late-keeping kinds as give promise of commercial value appear to have originated in the Baltic provinces or to have been transported at an early date from the countries to the west. These types—the Synaps for instance—have characteristically small leaves, slender twigs, and are less hardy than members of the groups cited above.

The "bloom," or glaucous covering, of the Russian apple is characteristic. It does not persist to the same extent, however under all climatic conditions. In eastern Quebec it fails to develop to the same extent that it does under the drier atmospheric conditions of the eastern states. As additional proof that this pruinose bloom is an immediate climatic effect, one has but to compare the Colorado Spy with that grown in New York. The smooth, thin skin and abundant bloom of the Colorado apple is characteristic in a greater or less degree of all varieties produced in the dry regions adjacent to the Rockies, as it is of the Russian apples in the more arid portions of that country.

The names of Russian apples are much confused. There is no pomological society in Russia to assist the fruit-grower in eliminating synonyms; on the other hand, the factors conducive to confusion are strongly in evidence. These are illiteracy on the part of the grower and the practice of propagating fruit trees from the seed instead of by grafting. Gibb says "nomenclature in Russia is hopelessly confused. Different names are given to the same apples in different localities, the same name to different apples growing in adjacent districts."

1598. Vladimir, one of the typical Russian cherries. The fruit is somewhat tapering to the stem. (×⅗)

Fruit-growers of the West, realizing that Americans should have a uniform system, at least in the nomenclature of these varieties, called a meeting made up of interested representatives of the fruit-growers' associations of South Dakota, Minnesota, Iowa and Wisconsin. These delegates, collectively styled the "Russian Apple Nomenclature Commission," met at La Crosse, Wisconsin, August 30, 31, 1898. They decided that it would be wise to attempt a grouping to be based upon "family resemblance." In accordance with this the following statement was adopted: "The varieties here grouped as members of the same families, while in a few cases differing somewhat in characteristics of tree, are so nearly identical in fruit that for exhibition and commercial purposes they are practically the same and should be so considered." It is to be regretted that a commission on nomenclature should take such a radical stand as this, because the characteristics of a variety cannot be changed by voting to call it by the same name as the other member of the group which it most resembles and almost, though not quite, duplicates. The trend of modern pomology is to preserve small differences, to differentiate rather than blend. The work of the future will consist in large part in studying small differences with a view of finding closer adaptations. The propriety of ignoring Russian nomenclature and the rule of priority is questionable, but in a measure is defensible on the grounds of a confused Russian nomenclature and the unpronounceableness of Russian names. The findings of the committee have on the whole met with the approval of those interested in Russian apples.

Russian cherries.

These, next to the apples, constitute the most clearly defined group of Russian fruits; yet many cherries commonly called Russian are in reality Polish, Silesian or German. The typical cherry of northern Russia is represented by the Vladimir type (Fig. 1598). This was first introduced into America as a distinct variety. Later importations and experience demonstrated that Vladimir was a type, not a variety. This type appears to have been grown in Russia for centuries from seeds and sprouts. In this way a special class has been developed. The Vladimir type is characterized by its dwarf stature—5 to 8 feet high—its peculiarly rounded and compact top, its dark red, meaty-fleshed fruit. Koslov-morello is evidently a light-colored juicy variety of Vladimir. The characteristics of the tree are the same as Vladimir, although when grown from seed in this country the seedlings exhibit considerable variation. The amarelles and weichsels of Germany have been grown in Russia for centuries, generally from seed, and have become specialized forms. Cherries of the Vladimir and Koslov-morello types are the hardiest of the cherries. The Vladimirs have not, as a rule, been productive in this country. The fruit-buds appear to be sensitive to cold and as easily injured as some of the recognized tender types of cherries. Although the trees are hardy, the introduction of this type has not extended the area of commercial cherry-growing in this country farther north than the regions already outlined by the profitable cultivation of Early Richmond.

Russian plums.

The plums imported from Russia do not differ materially from those of the domestica type in cultivation in this country. The trees are probably somewhat hardier than Lombard or Green Gage, but the fruit-buds are subject to winter injury wherever Lombard is uncertain. In the main they have been unproductive. Among the most widely tested varieties are Early Red, Moldavka and Merunka, all of the Lombard type.

Russian pears.

These are hardy handsome trees, but none bears fruit of good quality. Where blight is prevalent they are extremely susceptible. Among the hardiest of the class are Bessimianka (meaning seedless, which is only partly true), Gakovsky and Tonko-vietka. These thrive wherever the climate admits of the cultivation of the Oldenburg apple. The fruit ripens in August, and rots at the core if allowed to mature on the tree.

Russian apricots.

Apricots were brought to Nebraska and Kansas by Russian Mennonites about twenty-five years ago. A few of those named and distributed are likely to be retained in the fruit lists of the West.

Russian mulberries.

Russian mulberries have been widely sold as fruit-bearing plants by enterprising agents, but their use to the fruit-grower should be restricted to hedging and the formation of windbreaks. For these purposes they are valuable in the colder and more rigorous regions.

Russian peaches.

So-called hardy Russian peaches are sold, but they really belong to Bokara or Turkestan. The peaches of the Baltic provinces do not differ essentially from the ordinary Persian strain in form or hardiness.

In general.

The introduction of the Russian fruits has given us hardy types from which to breed varieties for northern latitudes. In Iowa, Minnesota and Wisconsin this work is under way. Seedlings and hybrids are appearing each year, which may be considered valuable additions to the fruit lists of these regions

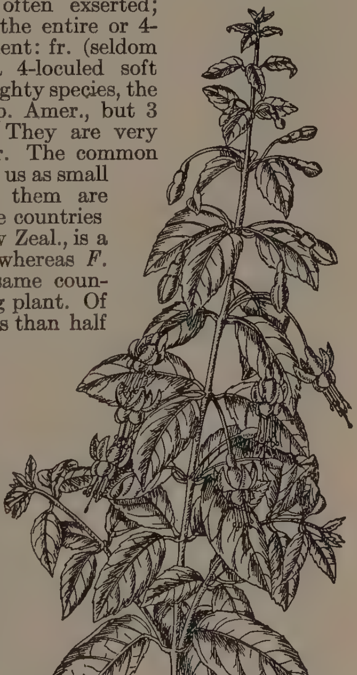
Literature.

But two books appear to have been written on Russian pomology up to 1838, one by Nicolai Krasno Glasov, 1848, the other by Regel, director of the Imperial Botanic Gardens, St. Petersburg, in 1868. The latter is called "Russkaya Pomologaya." It contains a description of 225 varieties of apples, nearly all of Russian origin. A wood-cut of each appears, in addition to 144 colored plates. Gibb calls it "a grand, good fundamental work." American literature on Russian fruits is mainly confined to three sources; the reports of the Montreal Horticultural Society, publications of the Division of Pomology, Department of Agriculture, Washington, and Bulletins of the Horticultural Department of the Iowa Agricultural College. To Charles Gibb, Abbotsford, Canada (Quebec), we are indebted for the faithful and accurate translation of the names given in the collection imported by the Department of Agriculture in 1870. This was adopted by the American Pomological Society in 1885.

John Craig.

FÙCHSIA (Leonard Fuchs, 1501–1565, German professor of medicine, and a botanical author). *Onagràceæ.* Handsome and popular flowering plants of greenhouses, conservatories, window-gardens and open grounds, blooming most freely in spring and summer.

Shrubs and small trees, with opposite, alternate or verticillate simple lvs.: fls. mostly showy, axillary or sometimes racemose and paniculate, usually pendulous, in shades of red and purplish and with some of the parts often white; tube prolonged beyond the ovary and bell-shaped to tubular, with 4 spreading lobes; petals 4, sometimes 5, or in some species wanting; stamens usually 8, often exserted; style long-exserted, the entire or 4-lobed stigma prominent: fr. (seldom seen under glass) a 4-loculed soft berry.—Seventy or eighty species, the greater part in Trop. Amer., but 3 or 4 in New Zeal. They are very variable in character. The common fuchsias are known to us as small herbs, but most of them are shrubs in their native countries *F. excorticata*, of New Zeal., is a tree 30–40 ft. high, whereas *F. procumbens*, of the same country, is a weak, trailing plant. Of the many species, less than half a dozen have entered largely into garden forms. The common garden kinds have come mostly from *F. magellanica.* This species was intro. into Great Britain from Chile in 1788, or about that time. It is variable in a wild state as well as in cult., and plants subsequently intro. from S. Amer. were so distinct as to be regarded for a time as separate species. Even at the present day some of



1599. Fuchsia magellanica var. globosa. (×¼) the forms of *F. magellanica* are commonly spoken of as species, so much do they differ from the type. As early as 1848, 541 species and varieties—mostly mere garden forms—were known and named (Porcher, "La Fuchsia, son Histoire et sa Culture"). The fuchsia reached the height of its popularity about the middle of the past century. At present it is prized mostly for window-gardening and conservatory decoration. The garden forms of the present day are with difficulty referred to specific types. The long-tubed or so-called speciosa forms are probably hybrids of *F. magellanica* and *F. fulgens* (Figs. 1603, 1604). Others are evidently direct varieties from the stem types. There are many full double forms. For the history and the garden botany of the fuchsia, see Hemsley in the Garden 9:284 and 11:70; also Watson, the Garden 55:74.

1600. Fuchsia magellanica var. Riccartonii. (×¼)

In mild climates, fuchsias make excellent outdoor shrubs, some of them withstanding frost. These are of the *F. magellanica* group. They are familiar to travelers in Ireland, and they may be seen as far north as the Shetland Islands. In California, many of the fuchsias are excellent and popular subjects for planting in the open. Under glass, forms of *F. magellanica* may be grown into large rafter shrubs, where they produce great abundance of bloom.

Fuchsias are among the most ornamental and popular of the cool greenhouse flowering plants. They may also be used in summer as bedding plants, and they are among the very few flowering plants that will bloom in the shade. If fair-sized specimen plants in 10- or 12-inch pots are desired, the best time to root them is the end of August. The best cuttings are secured from suckers that start from the base of the plants that are bedded out. The cutting should be 3 inches in length, and if the intention is to grow large specimens, pot them singly in 2-inch pots, in three parts sand, one part loam, and another of leaf-mold. Place the cuttings when potted in a shady position in a temperature of not less than 60° at night. When the very small plants are well rooted, shift them along into a pot 2 inches larger, using this time a compost of equal parts of loam, leaf-mold, and sand and add a third part of well-rotted manure. In this size of pot, the shoot will have made four or five joints, and should now be pinched to encourage side breaks. The plant, where it is stopped, will start into two breaks, and the strongest should be taken for a leader; pinch the weaker one when two leaves are well formed. Strict attention from now on should be paid to keep the plants in good shape. The side shoots must be kept in bounds, so that the symmetry of the plant is preserved, pinching the stronger ones hard and allowing the weaker to grow a little longer so that they gain more vigor. The leader may be allowed to make six pairs of leaves, and then be stopped, always choosing the strongest breaks to increase the height of the plant. Potting should be strictly attended to, never allowing the plant to form a mat of roots around the ball before it gets a shift into a larger pot. The potting material for all future pottings may be composed of two parts good fibrous loam, with an equal amount of well-rotted horse-manure, one part flaky leaves, and one part sharp sand. The whole should be as rough as can be conveniently used when working it equally around the ball of the plant, in the potting operation. It is necessary to have a good straight stake down the center of the plant to support it in an upright position. When the plant is well established in the pot in which it is desired to flower it, manure waterings will be in order, as these plants are gross feeders when in active growth. Green cow-manure, fertilizers, and soot secured from soft coals agree well with fuchsias. The amount to be used is an ordinary handful to two and a half gallons of water. Water twice in between with clean water. Give the last pinch to the plants about six weeks before they are desired to be in full flower.—For bedding-out purposes, cuttings may be rooted in the spring, and grown on into 5- or 6-inch pots. Old plants may be kept through the winter, in a cool light pit, from which frost is kept. Keep them rather dry during October, November, and December, only giving enough water to maintain the wood plump. In January they may be removed to a temperature of 50° by night, allowing a rise of 10° or 15° during the day. This temperature, by the way, is most suitable for fuchsias after they are rooted until they come in flower. After it is seen where all the live eyes are on the old plants, trim them into shape, and remove all the dead wood. Turn them out of the pots, and remove all the loose dirt from the ball with a hose with a gentle pressure of water on it. They may be potted in the same size of pot, and when well rooted in that, give them a shift two sizes larger. Pinch the plants two or three times during the winter, and one will be rewarded with better plants the second year than the first. If well attended to every year, fuchsias may be kept for many years, attaining an enormous size. Fumigate with hydrocyanic gas, during winter, and that, with syringings on all bright days, until they come in flower, will keep down insect pests. (George F. Stewart.)

A. *Fls. drooping* (Nos. 1–9).

B. *Tube of fl. mostly shorter than the calyx-lobes (or in F. speciosa sometimes as long again); petals obovate and retuse, convolute in the bud.*—Ladies' Ear-Drops.

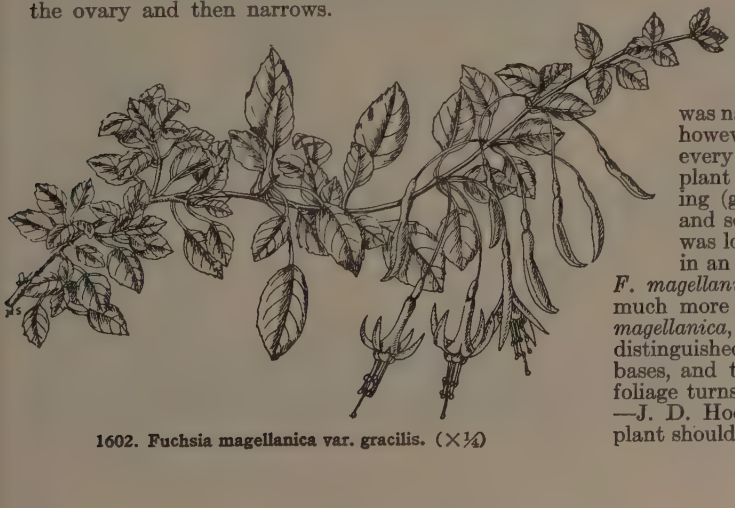
1. **magellánica**, Lam. (*F. macrostèma*, Ruiz & Pav. *F. macrostémma*, Auth. *F. coccinea*, Curtis, not Ait.). Tube little longer than the ovary, oblong or short-cylindrical; petals normally blue, and shorter than the red and oblong-lanceolate calyx-lobes; stamens long-exserted: lvs. opposite or in 3's, lance-ovate, very short-petioled, dentate. Peru and south to Terre del Fuego. B.M. 97 (*F. coccinea*). The leading types are as follows:

Var. **globòsa**, Bailey (*F. globòsa*, Lindl. *F. macrostémma* var. *globòsa*, Nich.). Fig. 1599. Lvs. opposite, short-petiolate, ovate, acute, lightly dentate, glabrous: fls. red-purple, axillary on slender peduncles, small and short, the bud nearly globular and the tips of the sepals cohering even after the fl. begins to burst; tube very short; petals erect, twice shorter than the calyx-lobes. B.R. 1556. Gn. 55, p. 75.—A profuse bloomer, and a common type amongst old-fashioned fuchsias. There is a form with variegated lvs.

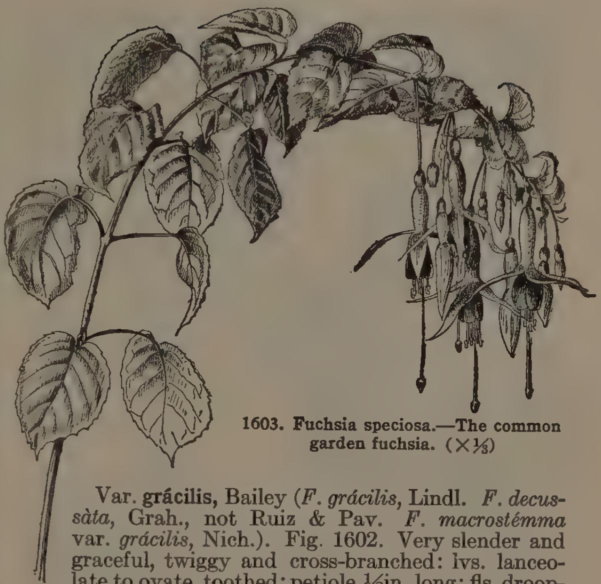
Var. **Ríccartonii** (*F. Ríccartonii*, Hort.). Fig. 1600. Very like var. *globosa* and reported to be a seedling of it, is a very hardy and floriferous form, standing in the open in Scotland, blooming particularly well in autumn: 6–10 ft., making a trunk 3 in. diam., and becoming wide-spreading: shoots slender: fls. red. J.H. III. 58:329.—A handsome and desirable fuchsia, said to have been raised at Riccarton, near Edinburgh, about 1830, but reported as originating in the Falkland Isls. Excellent in Calif.

Var. **díscolor**, Bailey (*F. díscolor*, Lindl. *F. Lòwei*, Hort.). Fig. 1601. Dwarf, compact and hardy: branches deep purple: lvs. rather small undulate-toothed: peduncles axillary, slender, exceeding the lvs.; fls. red, small, with slender, short tube and wide-spreading, rather narrow calyx-lobes, which are somewhat longer than the tube; petals obtuse, shorter than the calyx-lobes. Falkland Isls. B.R. 1805.

Var. **cònica**, Bailey (*F. cònica*, Lindl. *F. macrostémma* var. *cònica*, Nich.). Shrubby, very leafy: lvs. 3–4 together, toothed, ovate, the petiole one-third length of blade, pubescent: fls. axillary, solitary, on peduncles much longer than lvs.; calyx scarlet, the tube conical (or widest at base) and equaling the lobes; petals dark purple, erect and emarginate; small-fld. Raised from seeds brought from Chile. B.R. 1062.—Lindley says that it differs from *F. gracilis* in having broader lvs., being less floriferous, and in the conical tube which widens above the ovary and then narrows.



1602. Fuchsia magellanica var. gracilis. (×¼)



1603. Fuchsia speciosa.—The common garden fuchsia. (×⅛)

Var. **grácilis**, Bailey (*F. grácilis*, Lindl. *F. decussàta*, Grah., not Ruiz & Pav. *F. macrostémma* var. *grácilis*, Nich.). Fig. 1602. Very slender and graceful, twiggy and cross-branched: lvs. lanceolate to ovate, toothed; petiole ½in. long: fls. drooping on very long pedicels which are single or in pairs; tube slender, nearly as long as the narrow spreading lobes; calyx scarlet; petals purple, retuse, shorter than the long acute calyx-lobes. Chile. B.R. 847; 1052 (var. *multiflora*). B.M. 2507. Gn. 55, p. 74. Mn. 2, p. 186.—Perhaps a distinct species. A var. *variegàta* is advertised. *F. Thómpsonii*, Hort., is said to belong here.

With the *F. magellanica* set may be classed *F. corállina*. Hort., *F. élegans*, Paxt., *F. tenélla*, Hort., and others. There are apparently many hybrids. The short-flowered fuchsias are less popular than formerly, but many varieties are now in cult.

2. **speciòsa**, Hort. (*F. hýbrida*, Hort.). Figs. 1603, 1604. The greater part of present-day garden fuchsias are of the longer-tubed type shown in the illustrations. These are probably hybrid derivatives of *F. magellanica* forms and *F. fulgens*. Amongst the named sorts every gradation will be found, from the short-tubed Storm King to the Earl of Beaconsfield with fls. 3 in. long. The old *F. exoniénsis*, Paxt., B.M. 153, is figured as a very showy plant, marked by very long-pointed calyx-lobes and sharp-pointed buds, said to be a hybrid of *F. cordifolia* (a Mexican species) and *F. globosa*. The plant subsequently figured and cult. under that name does not agree, having shorter fls. and much less prominently pointed calyx-lobes.

3. **coccínea**, Ait. Not known to be cult. in Amer., and inserted here for the purpose of clearing up the synonymy of *F. coccinea*. This species appears to have been intro. before *F. magellanica*, and it was named *F. coccinea* by Aiton. *F. magellanica*, however, "usurped its name and spread it to every garden in the kingdom, whilst the true plant lingered in botanic gardens, lastly surviving (greatly to the credit of the Baxters, father and son) in that of Oxford alone." The species was lost from its intro. in 1788 to its rediscovery in an Oxford garden in 1867; meantime forms of *F. magellanica* passed as *F. coccinea*. "*F. coccinea* is much more graceful than any of the varieties of *F. magellanica*, flowers even more freely, and is readily distinguished by the almost sessile leaves with broad bases, and the hairy twigs and petioles; further, its foliage turns of a bright crimson when about to fall." —J. D. Hooker, B.M. 5740. Probably Brazilian. The plant should be looked for in collections.

4. **spléndens,** Zucc. Fig. 1605. Much-branched, shrubby: lvs. ovate-cordate, pale green, serrate: peduncles slender, axillary, solitary and single-fld.; fls. drooping, rather short; fl. 1½ in. long, scarlet tipped pale green, the base swollen and the tube then compressed; petals shorter than calyx-lobes, ovate, greenish; stamens much exserted, the anthers yellow. Mex. B.M. 4082. B.R. 28:67. G.C. III. 45:338. G. 1: 649; 9:693.

1604. The common garden fuchsia—F. speciosa.

BB. *Tube thrice or more the length of the calyx-lobes; petals pointed, nearly or quite as long as the calyx-lobes.*

5. **fúlgens,** Moc. & Sessé. St. somewhat succulent, glabrous, often red-tinged: lvs. large and coarse, cordate-ovate, soft, small-toothed: fls. in terminal leafy clusters or racemes, the red long-tubular calyx-tube 2–3 in. long and very slender at the base; the calyx-lobes short and pointed, greenish at the tip, not very widely spreading; petals deep scarlet, pointed, shorter than calyx-lobes; stamens only short-exserted. Mex. B.M. 3801. B.R. 24:1. Gn. 55, p. 75. R.H. 1881:150 (var. *pumila*).—A brilliant plant, sometimes seen in choice conservatory collections. Evidently one parent of the *F. speciosa* tribes. *F. pendulæflòra*, Hort., is supposed to be a hybrid, but the fls. very long like *F. fulgens:* lvs. ovate, acuminate, with violet midrib: tube of fl. 3–4 in. long, trumpet-shaped; fls. rich crimson shaded maroon. J.H. III. 51:301.

6. **triphýlla,** Linn. Fig. 1606. Low and bushy (18 in. high), pubescent: lvs. often in 3's, small, oblanceolate, petiolate, dentate, green above and purple pubescent beneath: fls. 1½ in. long, in terminal racemes, cinnabar-red, the long tube enlarging towards the top; petals very short; stamens 4, not exserted. St. Domingo, W. Indies. B.M. 6795. Gn. 41:32. I.H. 43, p. 94. G.M. 49:333. Gn.W. 5:389.—Known in botanical collections and sparingly in the trade. The species has a most interesting history, for which see the citations made above. Upon this plant Plumier founded the genus Fuchsia in 1703, giving a rude drawing of it. Upon Plumier's description and picture Linnæus founded his *F. triphylla.* Plumier's figure is so unlike existing fuchsias that there has been much speculation as to the plant he meant to portray. No fuchsia was known to have four stamens or to be native to the W. Indies. In 1877 Hemsley wrote of it: "The figure, however, is so rude that nobody, I believe, has been able to identify it with any living or dried plant. Possibly it is not a fuchsia at all in the sense of the present application of the name, for it is represented as having only four stamens." But in 1873, Thomas Hogg, of New York, secured seeds of a St. Domingo fuchsia which turns out to be Plumier's original, thus bringing into cult. a plant that had been unknown to science for 170 years. It came to the attention of botanists in 1882. For a discussion of further confusion in the history of this plant, see Hemsley, G.C. II. 18, pp. 263–4.

7. **venústa,** HBK. Branches slender, somewhat hairy: lvs. opposite and in 3's, elliptic, acute, entire, glabrous, somewhat shining: peduncles axillary, slender, about the length of the scarlet fls., more or less racemose above; fls. elongated, the tube 2 in. long beyond ovary and narrow-trumpet-shaped, the lobes ovate-lanceolate and acuminate; petals about equaling calyx-lobes, scarlet, the margins undulate. Colombia. F.S. 5:538. J.H. III. 49:243.

8. **boliviàna,** Carr. Compact, branching, 2–4 ft., producing the showy fls. in profuse drooping sometimes branched clusters: lvs. large, elliptic-ovate, acute or acuminate, toothed: fls. 2–3 in. long, trumpet-shaped, rich red. Bolivia. R.H. 1876:150. G.W. 8, p. 316.—Very like *F. corymbiflora*, but said to be more ornamental: fls. brilliant coral-red, the calyx-lobes and petals acuminate and equal or subequal, the former spreading-star-shaped or reflexed, the petals erect or close about the stamens; filaments red, anthers whitish; stigma very large, ovoid: fr. fleshy, violet-black.

9. **corymbiflòra,** Ruiz & Pav. Tall but weak grower, needing support when allowed to attain its full height, therefore excellent for pillars and rafters: lvs. large, ovate-oblong and tapering both ways, serrate, pubescent: fls. deep red, hanging in long brilliant corymbs; calyx-tube 3–4 in. long and nearly uniformly cylindrical, the lobes lance-acuminate and becoming reflexed; petals deep red, lance-acuminate, about the length of the calyx-lobes; stamens length of the petals. Peru. B.M. 4000. Gn. 11:70 (as F. boliviana); 55:74. F. 1841:161. H. U. 2, p. 324. Var. **álba,** Hort., has white or nearly white calyx-tube and -lobes. F.S. 6: 547. Gn. 55:74.—A very handsome plant, but not common

AA. *Fls. erect.*

10. **arboréscens,** Sims (*F. syringæflòra*, Carr.). A shrub: lvs. lance-oblong and entire, laurel-like: fls. lilac-scented, pink-red, small, with a short or almost globular tube, in an erect terminal naked lilac-like panicle; calyx-lobes and petals about equal in length. Mex. B.M. 2620.—Little grown, but excellent for winter-flowering; should not be lost to cult.

1505. Fuchsia splendens. (×¼)

11. **procúmbens,** Cunn. Trailing Fuchsia. Trailing Queen. Trailing, with slender much-branched sts.: lvs. alternate, small (⅓–½in. across), cordate-ovate, long-stalked: fls. solitary and axillary, apetalous, the short tube orange and the reflexing obtuse lobes dark purple, anthers blue: plant diœcious: berry glaucous-

red. N. Zeal. B.M. 6139. G. 35:97.—A very interesting little plant, suitable for baskets.

Species not known to be in the American trade are: *F. amplidta*, Benth. Fls. large, scarlet, long-tubed, drooping. Colombia. B.M. 6839.—*F. bacillàris*, Lindl. Compact, with short-jointed branches: fls. very small, flaring-mouthed, rosy, drooping. Mex. B.R. 1480.—*F. cordifòlia*, Benth. Fls. 2 in. long, slender, drooping, hairy, red, on very long pedicels. Mex. B.R. 27:70.—*F. Dominiàna*, Hort. Garden hybrid with long drooping red fls. of the speciosa type. F.S. 10:1004.—*F. excorticàta*, Linn. f. Shrub or small tree of New Zeal., reaching 40 ft. high and the trunk sometimes 2–3 ft. diam., the bark thin, papery and loose: lvs. alternate, ovate-lanceolate to lanceolate, entire or nearly so: fls. 1¼ in. or less long, solitary and drooping, trimorphic. B.R. 857.—*F. macrántha*, Hook. Largest-fld. fuchsia; 4–6 in. long, pink-red, in large, drooping clusters. Colombia, Peru. B.M. 4233.—*F. microphýlla*, HBK. Dwarf, small-lvd., with deep red, small axillary, drooping fls.: pretty. Mex. B.R. 1269.—*F. serratifòlia*, Ruiz & Pav. Fls. long-tubed, speciosa-like, on drooping pedicels from the axils of the whorled lvs., pink with greenish tinge: handsome. Peru. B.M. 4174.—*F. simplicicaùlis*, Ruiz & Pav. Lvs. usually in 3's, entire: fls. crimson, long and slender-tubed, in drooping clusters: resembles F. corymbifera. Peru. B.M. 5096.—*F. thymifòlia*, H.B.K. To 6 ft.: lvs. small, opposite or nearly so, ovate or roundish, downy above: fls. red, on axillary pedicels, the petals obovate and undulate. Mex. B.R. 1284.

L. H. B.

FUMÀRIA (*fumus*, smoke, the application perhaps to the smoke-like odor of roots or other parts of some species). *Fumariàceæ*, a family by some botanists united with *Papaveràceæ*. This genus includes the common fumitory, *F. officinalis*, formerly held in great repute for various ailments, but now practically banished from medical practice. Seeds are still rarely sold to those who have faith in old physic gardens. The plant has a large literature, which is especially interesting to those who delight in herbals. As an ornamental plant, it is surpassed by Adlumia. There are about 40 species of Fumaria in the Medit. region and Cent. Eu., and S. Afr.: mostly annual herbs, with compound much-dissected lvs., usually diffuse and branching, sometimes climbing, glaucous: corolla 1-spurred at base, and thereby distinguished at once from Adlumia; sepals 2, very small; petals 4; stamens 6, diadelphous: fr. a roundish 1-seeded indehiscent nutlet. *F. officinàlis*, Linn., the common fumitory, of Eu., is sparingly run wild in waste places: 2–3 ft. high: lvs. petioled, the segms. linear, oblong or cuneate and entire or lobed: fls. small, flesh-color with crimson tip, in narrow racemes. Variable.

L. H. B.†

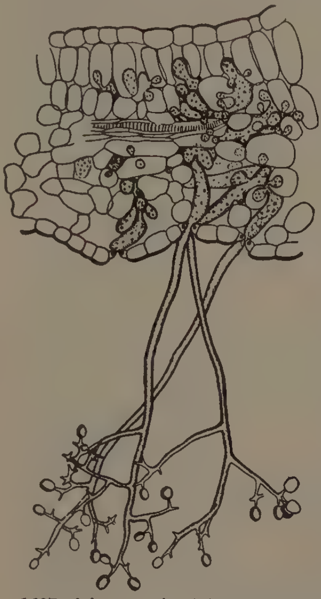
1606. Fuchsia triphylla. (×⅓)

FUMITORY: *Fumaria officinalis.*

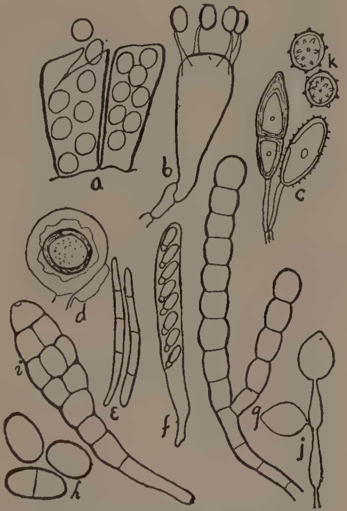
FÚNCKIA, FÚNKIA: *Hosta.*

FUNGI are plants. They differ from other plants chiefly in their lack of chlorophyll, the green coloring matter of green plants, and in the character of the substance of which their cell-walls are composed. This is sometimes spoken of as fungous cellulose, and has characters both of the cellulose of other plants and the chitin of insects. There are thousands of species of fungi, varying greatly in form and structure. Some forms are more or less familiar to everyone; for example, mushrooms, or toadstools, molds, mildews smuts and rusts. Other groups of plants often included under the term fungi are the slime-molds or myxomycetes and bacteria. While they have certain characters in common with fungi, they are sufficiently distinct to be considered separately.

The fungus plant consists of a vegetative feeding portion, the mycelium, which, in a way, corresponds to the roots of higher plants, and the fruiting structure, the sporophore. The latter bears the reproductive bodies, the spores, which, while much simpler in structure, function in the same way as do the seeds of higher plants (Fig. 1607). The sporophore is the part most often observed by the layman. The mushroom or toadstool, the puffball, the smut boil on corn, the white powdery mildew on the grape or rose, or the blue mold on stale bread or cheese, are almost entirely the sporophores and spore masses. The mycelium is usually buried in the substratum from which the food is derived and is thus not often observed. In fact it is often too minute and colorless to be seen with the naked eye. It may be observed as a white branching weft in the dung of mushroom beds or in the leaf-mold in the forest. This form is commonly spoken of as spawn. It may also be seen as a white weft-like growth between the bark and wood of rotting logs or dead trees, or as brown leathery sheets in the cracks of rotting logs. It sometimes appears as brown or black shreds or strands under the bark of dying trees. This form of mycelium strand or rhizomorph is characteristic of the often very destructive mushroom parasite of trees, *Armillaria mellea*. The spores of fungi are minute microscopic bodies cut off from the sporophores for the purpose of reproducing the plant. They are usually one- or two-celled, though often many-celled (Fig. 1608). They are often colorless, though they may be variously tinted or colored, greenish, brown, black, and so on. When placed in



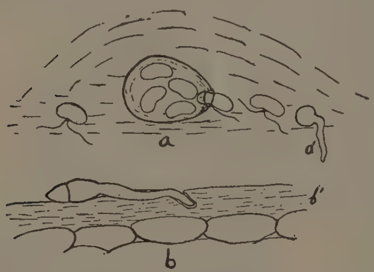
1607. A fungus. A mildew, showing the mycelium in the leaf-tissue and the hanging spore-bearing threads. (Much magnified.)



1608. Different spore forms of fungi.

a, Spore-sacs with spores of the peach leaf-curl fungus; *b*, spore-stalk with spores of a mushroom; *c*, two spore forms of the wheat-rust fungus; *d*, winter-spore of onion-blight parasite; *e*, spores of the beet leaf-spot pathogen; *f*, spore-sac with spores of the black-knot fungus; *g*, the summer-spores of the brown-rot pathogen; *h*, spores of the apple-tree canker fungus; *i*, spore of the alternaria blight fungus of ginseng; *j*, conidia of the late blight fungus of potatoes; *k*, corn-smut spores.

sufficient moisture, and given the proper temperature, they usually will germinate quickly, either sending out a sprout-like germ-tube (Fig. 1609, *b*) which on finding sufficient nourishment grows into mycelium, or the protoplasmic contents of the spore-cell may escape through an opening formed in the cell-wall, as one or more actively swimming and naked protoplasmic masses, called swarm-spores (Fig. 1609, *a*). These swarm-spores swim about in the water for a time, (usually less than an hour), then invest themselves with a cell-wall, and germinate with a germ-tube as above described (Fig. 1609, *a′*). This latter is the method of germination of the potato-blight fungus, *Phytophthora infestans.*—A fungus often produces two kinds of spores, the vegetative spores, conidia (Fig. 1608, *j*), produced usually in great numbers and repeatedly during the season for the purpose of multiplying the form, and the sexual, or resting-spores (Fig. 1608, *a, b, c, d, k*), adapted primarily to carry the fungus through periods unfavorable to growth, as dry seasons, winter and the like. Either form may, however, function as the other. They are disseminated by wind, water, insects, or by man himself.



1609. Germinating spores.
a, Conidium of late blight fungus germinating in a drop of water by swarm-spores; *a′*, swarm-spore germinating by germ-tube; *b*, ascospore of apple-scab fungus sending its germ-tube into the cuticle *b′* of the young apple.

Because of their lack of chlorophyll, fungi cannot assimilate their carbon directly from the carbon-dioxid of the air as can the green plants. They must make use of the food substances already manufactured or elaborated by other plants or animals. With respect to the nature of the substratum from which fungi obtain their food-supply, they are of two general types, saprophytes, those that can feed and develop on non-living organic substances (chiefly dead parts of plants and animals); and parasites, those that may grow upon and take food from living organisms. A true or obligate saprophyte can feed only upon non-living organic substances. There are great numbers of such species, attacking dead and fallen trees, stems and leaves of plants or the dead bodies of animals, infesting dung and other debris, breaking up the complex organic substances into simpler form, and deriving therefrom the food and energy for their development. Most mushrooms, toadstools, molds and the like, are obligate saprophytes, playing the rôle of disintegrators in the ever-changing cycle of nature. An obligate parasite, on the other hand is, in nature at least, compelled to derive its nutrition through direct attack on the living tissues of other plants or of animals. Of such fungi, the rust- and smut-producing parasites, the leaf-curl fungus of the peach, and the potato-blight organism are good examples. Between these extremes are to be found very many forms which, during a part of their active development, live as parasites, and during the remainder as saprophytes. The apple-scab fungus is a good example. It passes the summer as an active parasite upon the leaves and fruit of the apple, but in the autumn and spring continues its growth and development in the fallen leaves, producing the sexually formed ascospores which in the spring infect the next crop. Other forms, which usually lead a saprophytic existence on the dead and fallen parts of plants, may, under special conditions, take on a parasitic habit. A good example is a common saprophyte, a species of Botrytis, common in greenhouses. When there is an excess of moisture or the plants are in any way weakened, this fungus finds it easy to pass from a saprophytic life on the dead leaves, to that of active and destructive parasitism on the living leaves. It is sometimes destructive to lettuce. Fungi are in general favored by abundance of moisture. For this reason in a wet season mushrooms appear in great profusion, and epidemics of plant-disease-producing fungi often occur over wide areas, causing great losses to the agriculturist. The loss from potato-blight in New York state alone often amounts in wet seasons to over $10,000,000. Warm weather is generally favorable to fungus growth, but there are some forms, like the potato-blight fungus, which flourish only during relatively cool periods. This parasite occurs only in temperate regions, being unknown in the hot low lands of tropical and subtropical regions. The peach leaf-curl fungus is apparently favored as much by the low temperature as by the rains of a wet spring. Other forms seem to thrive best in dry climates, as for example the powdery mildew of grapes.

1610. Colonies of the rust fungus on the leaf of a hollyhock.

1611. Colonies of a fungus on a plum leaf. The dead tissue sometimes falls out, leaving a shot-hole effect.

While many fungi are destructive agents of the crops of the agriculturist, causing him heavy losses, most fungi are active co-laborers with him, bringing about, as has been seen, the disintegration of compost, on which the farmer depends so largely for increased crop-production. Other fungi, like the yeasts and certain molds, are necessary agents in the arts and manufactures, as for example, the use of yeast in bread-, beer- and wine-production, molds in cheese-ripening, and so on. The value of these fungi lies chiefly in their ability to produce fermentations of various sorts or to give flavors to the products. Many fungi are edible, as for example the large fruit bodies of mushrooms, puffballs and truffles. While their value as food is perhaps often overestimated, they are valuable and form no unimportant part of the food of many people, especially in Europe. They are to be regarded chiefly as delicacies. The truffles and the cultivated mushroom, *Agaricus campestris*, are perhaps the best known. A delicacy known to relatively few is the large smut boils occurring on *Zizania latifolia*. Some fungi are poisonous, as for example the deadly Amanita, the fly-agaric among mushrooms, and the ergot, a fungous parasite of rye and other grasses.

H. H. Whetzel.

FUNGICIDES: *Diseases and Insects.*

FUNKIA: *Hosta.*

FUNTÙMIA (*Funtum* is one of the vernacular names of *F. elastica*). *Apocynàceæ.* Three trees, sometimes very tall, of Trop. Afr., formerly placed in Kickxia, one of them being a rubber tree. *F. elástica*, Stapf, reaches 100 ft., with a cylindric trunk and pale spotted bark: lvs. oblong or lance-oblong, undulate: fls. white or yellowish in short-peduncled many-fld. dense cymes, the corolla-tube constricted above the base, the lobes oblong and obtuse; stamens inserted well down in the corolla-tube; disk 5-parted: follicles oblong-clavate, woody. Offered in Eu.; yields the Lagos caoutchouc.

FURCRÆA (Ant. François de Fourcroy, 1755–1809, chemist). Syn., *Fourcroya, Fourcræa, Furcroya, Furcræa. Amaryllidàceæ.* Succulent desert plants from tropical America.

Some with spiny foliage like Agave, others with minutely toothed margins like Beschorneria. They occasionally bear immense loose panicles of greenish white fls., suggesting those of *Yucca filamentosa*, which are known to every plant-lover of the N. The perianth of Furcræa is whitish and wheel-shaped; in Agave greenish yellow, funnel-shaped. The filaments in Furcræa have a cushion-like swelling at the base, which is absent from Agave.

Furcræa is cultivated much in the same way as Agave, except that the furcreas are given more heat and water. *F. gigantea* has a very pretty variegated form, which makes a useful pot-plant.

As a rule, furcreas bear fruit not more than once, and then die without producing suckers. However, they produce while in flower an immense number of bulbels, which may be used for propagation. It is impossible to say at what size or age the plants will bloom. Grown in pots, they may take a century. On the other hand, plants from bulbels have been known to flower at three years. Seeding is usually rare.

A. *Lvs. rough-margined but not toothed, glaucous, striate-roughened beneath: infl. pubescent: pedicels short.* SERRULATÆ.

1. **longæva**, Karw. & Zucc. Slender unbranched tree, up to 50 ft.: lvs. rigidly outcurving, narrowly lanceolate, gradually acute, concave, 3–6 x 60 in.: infl. 15 ft., broadly conical, short-stalked; fls. 1¼–1½ in.; ovary rather longer than segm.: caps. elongated, narrowed below; seeds small (⅙ x ¼in.): bulbels unknown. S. Mex. to Guatemala. Zuccarini, Act. Acad. Leop. Carol. 16, pt. 2:48. M.D.G. 26, p. 10. Bateman, Orchid. of Mex. & Guat. Vignette to pl. 16. B.M. 5519, (habit). Herbert, Amaryll., pl. 34.—A similar if separable species is reported for Bolivia. The most remarkable dracænoid tree, flowering when extremely old, and then dying, like others of its genus.

2. **Roézlii**, André (*Agàve argyrophýlla, A. Tonelìàna, Beschornèria floribúnda, Lília règia, Lílium règium, Roézlia règia, R. regìna, Yúcca argyræa, Y. argyrophýlla, Y. Parmentièri, Y. Tonelìàna*, Hort.). Trunk becoming 6 ft. or more: lvs. rather flaccidly spreading, lanceolate, acute, concave or plicate, 3–5 x 50 in.: infl. 10–15 ft., pubescent, the moderately broad panicle short-stalked; fls. 1¾ in.; ovary and segm. about equal: caps. ellipsoidal, scarcely stipitate: freely bulbiferous, the bulbels elongated. S. Mex. R.H. 1887, p. 353. B.M. 5519 (as to details); 7170 (as *F. Bedinghausii*). G.C. III. 9, p. 489; 36, p. 45; 46, p. 340.—The common plant grown along the Riviera, often as *F. longæva*, but more commonly as *F. Bedinghausii*, with which the synonymy is confused

3. **Bedinghaúsii**, Koch (*Beschornèria multiflòra* Hort. *Yúcca Prínglei*, Greenm. *Roézlia* or *Yúcca bulbífera*, Hort.). Trunk scarcely 3 ft.: lvs. rather rigidly outcurving, lanceolate, acute, rather flat, 2–3 x 18–24 in.: infl. 10–15 ft., the rather narrow panicle little longer than the scape; fls. 1½ in.; ovary and segm. about equal: caps. broadly oblong, abruptly stipitate; seeds moderate (¼–⅓ x ½ in.): freely bulbiferous, the bulbels ovoid. Cent. Mex. B.H. 13, p. 327. Ann. Jard. Buitenzorg. II. Suppl. 3:44. G.W. 7, p. 101.

AA. *Lvs. smooth-margined, typically toothed, usually green, not striate.* EUFURCRÆA.

B. *Prickles rather small and close set: lvs. narrow; margin straight.*

4. **cubénsis**, Vent. (*F. hexapétala*, Urban. *Agàve cubénsis*, Jacq. *A. bulbífera*, Salm? *A. hexapétala*, Jacq. *A. mexicàna*, Lam. *A. odoràta*, Pers). Nearly trunkless: lvs. narrowly lanceolate, spreading, smooth, about 2 x 50 in.; teeth nearly straight, 1/12–⅛in. long, ⅔–1 in. apart: infl. 10–15 ft., long-stalked, nearly glabrous; fls. 2 in.; ovary fusiform, about equaling the segm.: caps. small, broad, stipitate; seeds small (¼–½ in.): bulbels ovoid. Cuba and Haiti. Jacq., Stirp. Amer. :175. Ann. Jard. Buitenzorg. II. Suppl. 3:40.—As badly confused as *Agave americana* and actually rarely seen in gardens: apparently the original henequen of early writers on the W. Indies, its fiber called cabuya. A related Yucatan species, the cahum, with less lanceolate lvs. and ovary exceeding the perianth, is *F. Cahum*, Trel., Ann. Jard. Buitenzorg. II. Suppl. 3:39.

BB. *Prickles large or prominently raised and rather distant, curved,—suppressed in certain forms.*

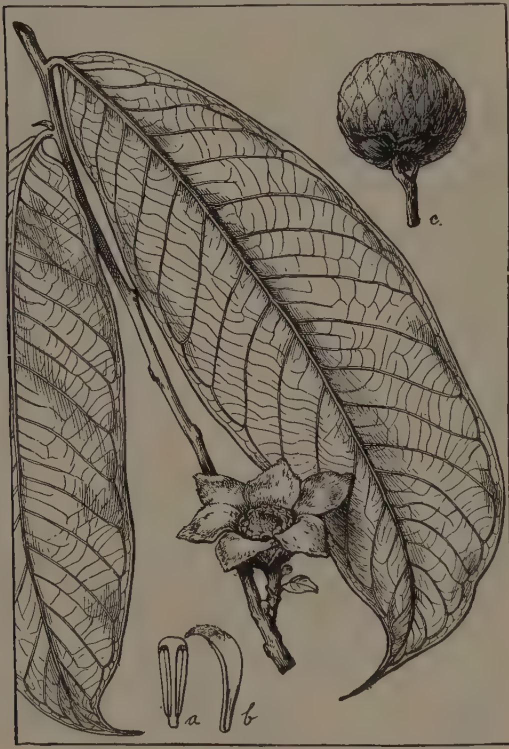
C. *Shape of lvs. oblong-lanceolate, large.*

5. **pubéscens**, Tod. Nearly trunkless: lvs. spreading, concave, smooth, about 3 x 60 in.; teeth ⅕in. long, ⅔–1⅕in. apart: infl. 15–20 ft., rather short-stalked, pubescent; fls. 2¼ in.; ovary 1 in.; segm. 1½ in.: caps. large, broad, variously stipitate: bulbels ovoid. Mex (?). Giorn. Soc. Sci. Palermo 14:5–7. Ann. Jard. Buitenzorg. II. Suppl. 3:43. B.M. 6160(?) (depauperate). Related species are: **F. élegans**, Tod. of Guiana, with lvs. 5 in. wide with hooked blackening teeth ⅕–⅓in. long and 1⅗ in. apart, glabrous long-stalked infl., and leafy-tipped bulbels. Hort. Panorm. 4. **F. macrophýlla**, Hook., established in the Bahamas and Jamaica (probably from the south) with teeth ½in. long and 3⅓ in. apart, broad umbonate caps. and ovoid bulbels. Hook. Icon. 2501. Ann. Jard. Buitenzorg. II. Suppl. 3:37, 45. **F. andìna**, Trel. (*F. Deledevántii*, and *F. altíssima*, Hort.?), of E. Peru, with nearly as large and distant teeth, short-stalked infl., cuboid caps. and conical-ovoid bulbels. Ceara or Pernambuco hemp is ascribed to *F. agavephýlla*, Brot. (*F. cubénsis*, Mart. *Agàve inérmis* and *A. subinérmis*, Roem.), the caraguata assu of N. E. Brazil., Marcgrav. & Piso, Brazil, p. 111, of this same group.

6. **Sellòa**, Koch. Trunk finally 3–5 ft.: lvs. spreading, concave and revolute or plicate, rough-backed, about 3 x 50 in.; teeth ⅕–¼in. long, 1⅓–1⅗ in. apart, variously curved: infl. tall, stalked, glabrous; fls. 1⅗ in.; ovary ⅔in.; segm. 1 in.: caps. not known: freely bulbiferous. Colombia. B.M. 6148.—Frequently meant when the name *F. cubensis* is used. A handsome white- or finally yellow-margined plant, frequent in cult. is **F. Sellòa marginàta**, Trel. (*F. Líndenii*, Jacobi. *F. cubénsis Líndenii*, Hort. *Agàve cubénsis striàta*, etc., Hort.). Wiesner Festschr., p. 350. I.H. 21:186. G.W. 10, p. 212; 11, p 135; 16, p. 162. G.C.

III. 23, p. 227 (as *F. gigantea*). A form of this, rosy tinged and without marginal prickles, **edentàta**, Trel., has been intro. from the Colombian Andes recently by Pittier.

7. **Humboldtiàna**, Trel. (*Yúcca acaùlis*, HBK.). Trunk finally 10 ft.: lvs. spreading, nearly flat, grayish, smooth, 5–6 x 60 in.; teeth ⅛–⅕ in. long, usually divergently twinned from the tops of green prominences, 1–2½ in. apart: infl. 25–40 ft., long-stalked; fls. 2–2½ in.; ovary ⅘–1 in.; segm. 1⅓–1½ in. Venezuela. Ann. Jard. Buitenzorg. II. suppl. 3:38.—Called maguey de cocui by Humboldt; now commonly known as cocuiza brava in contrast with an unarmed cult. form, the cocuiza mansa, which may prove not to differ from *F. inérmis*, Drum. (*F. cubénsis inérmis*, Baker. *F. altíssima*, Hort. Franceschi). B.M. 6543. Intermediate between this and the next is the cabuya of Cent. Amer., *F. Cabùya*, Trel., which likewise presents armed and toothless forms. Ann. Jard. Buitenzorg. III. suppl. 3:36, 37.



1612. **Fusæa longifolia.** (×½)
a, perfect stamen; *b*, petal-like staminode; *c*, fruit.

8. **gigantèa**, Vent. (*F. Barilléttii*, *F. fœtida*, *Agàve fœtida*, Linn. *A. gigantèa*, *Âloe fœtida*, Crantz. *Fùnium pilíferum*, Willem.). Nearly trunkless: lvs. broadly oblanceolate, nearly flat, undulate, somewhat roughened beneath, 5–8 x 60–100 in., entire: infl. 25 ft., long-stalked, rather narrow; fls. 1⅗ in., with ovary and segm. equal: caps. unknown: freely bulbiferous. S. E. Brazil. DC., Pl. Gr. 126, 126*a*. Redouté, Lil. 476. B.M. 2250. Perrine, Senate Doc. 300:5. B.H. 10:34. Indian For. 35:23. Mart., Fl. Bras. 1:44. Ann. Mus. Marseille. II; 8, p. 125. Squier, Fibre Pl., 2. Jacq. Icon. 379. Commelin, Hort. Amst. 2:18.—The Mediterranean hemp, Mauritius hemp, taretra, green aloe, or pita, intro. by way of Madagascar and hence called Malgache aloe. Varies with moderate toothing, var. **Willemetiàna**, Roem. (*F. Commelìnii*, *Agàve Commelìnii*, Auct.), the Creole aloe. Ann. Jard. Buitenzorg. II. Suppl. 3:35. With broad median creamy variegation, the unarmed form is var. **mèdio-pícta**, Trel. (*F. gigantèa variegàta*, Hort. *F. variegàta*, Hort. *F. Watsoniàna*, Hort.). G.C. III. 23, p. 243. Ann. Jard. Buitenzorg. II. Suppl. 3:41, 42, 46–8.

9. **tuberòsa**, Ait. (*F. interrúpta*, *F. spinòsa*, *Agàve spinòsa*, *A. campanulàta*, *A. tuberòsa*, *Yúcca supérba*, Auct.). Nearly trunkless: lvs. broadly lanceolate, nearly flat, 8 x 50–70 in.; teeth usually ⅕in. long and ⅔–1⅓ in. apart, sometimes absent toward the end or below: infl. 25 ft.: caps. unknown: freely bulbiferous, the bulbels elongated. Cuba and Haiti and, in somewhat differing forms, in Porto Rico and through the Lesser Antilles. Rep. Mo. Bot. Gard. 18:1–4 R.H. 1877, p. 233. Cyclo. Amer. Agric., II. p. 290. Gt. 1852:3. Yearbook Dept. Agric. 1904:31. Ann. Mus. Firenze. 1:4. Commelin, Hort. Amts. 2:19. —Commonly called silk-grass, sometimes maguey or cocuiza: apparently the Haitian cabuya of early writers. With the teeth twinned, as they are sometimes in *F. Selloa* and characteristically in *F. Humboldtiana*, it is var. **geminispìna** (*F. geminispìna*, Ait.)

William Trelease.

FURZE: *Ulex*, particularly *U. europæus.*

FUSÆA (probably from Latin *fundo*, signifying melted or fused together, referring to the carpels). *Annonàceæ.* South American trees or shrubs, resembling Annona in the form of fruit, a solid, spheroid syncarpium composed of one-ovuled carpels fused together, but differing from that genus in having its petals imbricate or overlapping and in the outer circles of its stamens which are sterile and petaloid.—A genus of very few species. *Fusæa longifolia* was first described as *Annona longifolia* by Aublet. It was afterwards placed in the genera Duguetia and Aberemoa, from the last-named of which it was set apart by Baillon as the type of a subgenus or section Fusæa. In the genera Duguetia and Aberemoa, however, the carpels are discrete, or separate, and not fused together; in the former the indumentum is usually stellate-pubescent or scurfy, and in the latter the carpels are not only quite distinct but are borne on short pedicels. From the structural features above mentioned, it is evident that it merits generic rank.

longifòlia, Safford (*Duguètia longifòlia*, Baill. *Annòna longifòlia*, Aubl.) Pinacoua. Carib Apple. Fig. 1612. A small tree: lvs. oblong-acuminate, mucronate and smooth: fls. issuing from near the base of small branchlets growing from the axils of the lf.-scars of the preceding year, the 2 series of petals much alike; outer stamens sterile and petaloid: fr. ovate-globose, resembling a solid ball, its surface reticulated with shallow impressed lines, nearly smooth, flesh-colored. Guiana.—According to Aublet, the fr. has a good flavor and is eaten with relish by the Garipon and Galiba (Carib) Indians of French Guiana. Intro. into Fla. as a fr.-plant, but very little known. Closely related to this species and possibly identical with it is the Peruvian *F. rhombipétala*, Safford (*Annòna rhombipétala*, Ruiz. & Pav.) with petals clothed on the outside with appressed sericeous hairs, outer stamens petaloid and connivent as in *F. longifolia*, ⅕in. long, smooth near the base and minutely puberulent on the outside near the apex; and obovate-oblong lvs. with short thick petioles and sharply acuminate apices, the midrib and lateral nerves impressed on the upper surface and prominent beneath, the extremities of the latter connected by a submarginal nerve almost continuous from the base to the apex.

W. E. Safford

XLV. Ferns in a public garden, with springtime bloom.

G

GÀGEA (Sir Thomas Gage, British botanist, died 1820). *Liliàceæ.* Seventy-five or more small herbs of Eu., N. Afr. and east to China and Japan, allied to Ornithogalum, mostly hardy and sometimes grown in the open. Fls. white, yellow or rose, few on the top of the mostly low peduncle or scape: lvs. radical, mostly only 1, and sometimes on the st. and represented by bracts under the umbel: perianth persistent, with distinct segms.; stamens 6; ovary sessile or short-stipitate, 3-loculed: bulbs small. The gageas require the cult. of ornithogalums. They appear not to be in the American trade. **G. Liotárdii,** Schult. f., the gold-star, is from Eu. and eastward; a well-recommended alpine, 4–6 in. high, with yellow fls., making grassy mats: radical lf. usually 1, fistulose; scape-lvs. 2, one of them larger and at base convolute.—**G. lùtea,** Ker (*G. fasciculàris,* Salisb.), the yellow star-of-Bethlehem has yellow fls. with backs of segms. green, opening only in forenoon: radical lf. 1, linear, 6–18 in. long: scape short, with 1–3 bracts. Eu. to Himalayas. B.M. 1200. **G. bracteolàris,** Salisb. (*G. stenopétala,* Reichb.), is pale yellow: lf. 1 at base, linear-lanceolate and glaucous; st.-lvs. opposite, lanceolate, pubescent and fringed. Eu.

L. H. B.

GAILLÁRDIA (named for M. Gaillard, a patron of botany in France). *Compósitæ.* Showy annual and perennial herbs largely cultivated in borders and flower-gardens.

Leaves alternate, more or less toothed, and spotted: fls. in solitary and usually very showy heads, the rays yellow and red and always neutral, the disk-fls. purple and fertile; involucre broad, the bracts in 2 or 3 series, hairy; ligules 3-toothed or 3-cleft, giving a fringed appearance to the fls.—There are 12 species, all American, mostly from the far W.

1613. Gaillardia pulchella var. picta. (×⅖)

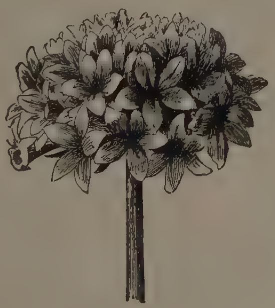
There are two types of gaillardias,—the annual forms, which are derived from *G. pulchella* and *G. amblyodon,* chiefly from the former; and the perennials, which issue from *G. aristata.* The gaillardias are conspicuous for profusion and duration of flowers. A constant succession is produced all summer until very late into the autumn. Besides their use as border or bedding plants they are good for cut-flowers, as they last well in water. They thrive best in light, open, well-drained soil, and should have full sunlight and air. In heavy or wet soils the plants are often winterkilled. The perennial forms are propagated by division, seeds or cuttings in August or September; also by root-cuttings in early spring. They usually do not breed true from seed and as better plants are produced by cuttings it is the most satisfactory method of propagation. *G. grandiflora* and its many varieties are garden forms of *G. aristata* (see Gt. 49, p. 583. G. 7:499). Some of the more recent introductions have highly colored flowers of extraordinary size, at least 4 to 5 inches in diameter. Another kind has quilled florets (*G. fistulosa*) of which Buffalo Bill is an excellent example,—a large, pure yellow with a narrow disk. Vivian Grey is also a remarkable and most distinct form, with clear yellow fringed rays, and disk of the same color. More recent introductions include *G. kermesina splendens* with narrow canary-yellow rays and rich crimson disk, and *G. sulphurea oculata* with pale sulfur, and bright maroon disk-flowers. Other trade names referable to no botanical species are *G. hybrida grandiflora, G. Josephus, G. semiplena,* and *G. Loiselii* (=*picta Loiselii,* H.F. II. 8:329?).

A. *Annual gaillardias: fls. normally mostly red.*

amblỳodon, Gay. One to 2 ft., erect, leafy, hirsute: lvs. oblong or spatulate, sessile and auriculate, entire or nearly so: lobes (or teeth) of disk-corollas short and obtuse; rays numerous, brown-red or maroon throughout their length. Texas. F.S. 21:2149.—Somewhat cult. amongst garden annuals, and worthy.

pulchélla, Foug. Erect, branching, 12–20 in., soft-pubescent: lvs. oblong, lanceolate or spatulate, rather soft, nearly sessile, either entire or the lower ones lyrate-pinnatifid: lobes of disk-fls. acute or awned; heads 2 in. across, the flat rays yellow at top and rose-purple at base. Ark. and La. to Ariz. B.M. 1602; 3551 (as *G. bicolor*).

Var. **pícta,** Gray (*G. pícta,* Hort.). Fig. 1613. The common garden form under cult., having larger heads and of various colors. B.M. 3368. R.H. 1852:20. V. 16:181. In one form (*G. fistulòsa, G. tubulòsa, G. Lorenziàna,* Hort.), the ray-florets and sometimes the disk-florets are enlarged and tubular. Fig. 1614. R.H. 1881, p. 377; 1885:156.



1614. Gaillardia pulchella, the form known as G. Lorenziana. (×⅕)

AA. *Perennial gaillardias: fls. normally yellow.*

aristàta, Pursh (*G. grandiflòra, G. lùtea, G. máxima,* and *G. perénnis,* Hort.). Erect, 2–3 ft.: lvs. rather thick, lanceolate or oblong, sometimes spatulate, varying from entire to sinuate pinnatifid: lobes of disk-corollas acute or awned; heads 3–4 in. across, the flat rays yellow, or in cult. varying to red (particularly at the base). Plains W. B.M. 2940. B.R. 1186. Gng.

2:345. Gn. 45, p. 325. A.F. 5:329.—This is the common perennial gaillardia of gardens (cult. under many names). Blooms the first year from seed. From *G. pulchella* it is distinguished by taller growth, firmer lvs., yellower heads, and less attenuate lobes of the disk-fls.; but it is practically impossible to distinguish the two, except that one is annual and the other perennial.

N. Taylor.†

GALÁCTIA (from the Greek, *milk;* some species said to yield a milky juice, which is improbable). *Leguminòsæ.* Prostrate or twining, perennial herbs or shrubs, mostly of the warm regions of America, only seldom cultivated.

Plants usually with pinnately 3–9-foliate lvs., and axillary, interrupted racemes of perfect, more or less perigynous fls.: calyx short, 4-lobed, bracted; corolla papilionaceous; standard broad; stamens 10, diadelphous; ovary 1, superior, 1-celled, with many ovules; style beardless: fr. a linear, straight or slightly curved legume. Cleistogamous fls. sometimes produced.—There are many species, but of very little horticultural value. The two following have been advertised in the past but are probably not now on the market.

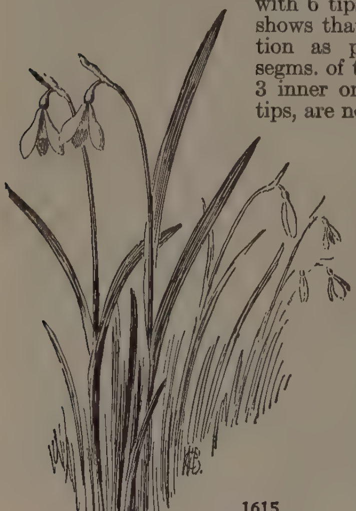
regulàris, BSP. (*G. glabélla,* Michx.). Lvs. with 3 lfts.: panicles mainly shorter than the lvs.: lfts. elliptical, often notched at the tip, 1–2 in. long, glabrous: corolla violet-purple. Dry sandy soil, N. Y. to Fla. and Miss. B.B. 2:335.

Élliottii, Nutt. Lvs. with 7–9 lfts.: panicles longer than the lvs.: lfts. elliptic-oblong, notched, pubescent beneath, ½–1¼ in. long: corolla white tinged with red. Dry sandy soil, S. C. to Fla., along the coast.

K. M. Wiegand.

GALÁNTHUS (Greek, *milk flower*). *Amaryllidàceæ.* Snowdrop. Spring-blooming bulbs (one autumnal), with solid scapes and solitary nodding white flowers.

Bulb tunicated, small: lvs. 2–3, strap-shaped: perianth without tube, outer and inner segms. unlike; stamens 6: fr. a 3-valved caps., more or less fleshy.—Probably a half-dozen species, in Eu. and W. Asia. The flowers of snowdrops (*G. nivalis,* Fig. 1615) are amongst the smallest and daintiest of common hardy cult. spring-blooming bulbs. They often bloom in early March, before all the snow has gone. Their pendulous white fls., with the "heart-shaped seal of green" dear to Rossetti, hold a unique place in the affections of lovers of gardens. At first sight the fls. seem to have 3 large white petals, inclosing a green-and-white tube with 6 tips, but a second glance shows that the parts that function as petals are the outer segms. of the perianth, while the 3 inner ones, with their 2-lobed tips, are not grown together, but overlap slightly, forming a rather crude but stiffish tube. Each plant has a globose coated bulb, 2–3 lvs., grows 6–9 in. high, and bears usually only 1 nodding fl., which emerges from a spathe. Behind the perianth is the globose green ovary.



1615. The snowdrop—Galanthus nivalis. (×½)

In a congenial spot, moist, cool and shady, the plants increase satisfactorily, and sometimes, without any care whatever, form a bed from which thousands of flowers may be picked at what is, perhaps, the most desolate and wearisome moment of the year. The leaves are linear and channeled, and in dark, shining masses make a rich, quiet effect. They come out with the flowers, attain their full growth later, and commonly die down in midsummer or fall. The bulbs are cheap, and should be ordered in liberal quantities. Plant in the autumn, as for other hardy bulbs; set 3 to 4 inches deep in mellow soil, and close together.

An era of new interest in snowdrops began about 1875, with the introduction of the "giant" kind (*G. Elwesii,* Fig. 1616), but those who do not care for "large violets" will be likely to cling to the small snowdrops. Nevertheless, *G. Elwesii* is very distinct, and should be the first choice if any large kinds are desired, and to secure the best forms the connoisseur should buy imported bulbs of its varieties. The only kinds known so far to possess a patch of green at the base of the inner segments are *G. Elwesii* and *G. Fosteri.* Considering that there are only two main types in this genus, *G. nivalis* and *G. Elwesii,* the profusion of Latin names (especially since 1888, the date of Baker's "Handbook of the Amaryllideæ") is rather trying, except to the connoisseur who, unlike the general public, is chiefly interested in the larger-flowered forms and the novelties.

There are several types of minor importance. The autumn-flowering kinds, representing many Latin names, as *G. octobrensis, G. corcyrensis, G. Reginæ-Olgæ,* are usually weak-growing plants. However, much is hoped from *G. cilicicus,* especially by the florists, who have hitherto found no snowdrop that could be profitably forced for Christmas. Doubleness seems to add nothing to the beauty of snowdrops. So far it seems to have affected only the inner segments of *G. nivalis* and *G. Elwesii.* Yellow snowdrops are also practically unknown in America. In these the heart-shaped spot and the ovary are yellow instead of green. Of these, *G. flavescens* is perhaps one of the best.

a. *Lvs. merely channeled, not plaited.*

b. *Width of lvs. small, 3–4 lines.*

c. *Base of lvs. not very narrow.*

1. **nivàlis,** Linn. (*G. Shárlockii,* Hort.). Common Snowdrop. Figs. 1615, 1616. Bulb 6–12 lines thick: basal sheath split down one side: lvs. linear, glaucous, finally 6–9 in. long: outer perianth-segms. oblong, 6–12 lines long; inner segms. green only at the sinus. Feb., March. Pyrenees to Caucasus. R.H. 1880, p. 148. G.M. 34:154. G.C. II. 11:237. Gt. 48, p. 232.—There are large-fld. and double forms. Var. **corcyrénsis** and others flower in Nov. G.W. 2, p. 250. At least 2 varieties have yellow instead of green markings. Var. **flavéscens,** S. Arn. The markings on the inner segms. of the perianth and on the ovary are yellow, and the sts. are more yellow than green. Useful for Alpine gardens. G. 31:149. Var. **refléxus** has outer segms. reflexed. G.M. 34:155. Var. **octobrénsis** (var. *octobrìnus,* Voss. *G. octobrénsis,* Hort.). Albania. Known in cult. as a form blooming in England late in Oct.

cc. *Base of lvs. very narrow.*

2. **cilícicus,** Baker. Less robust than *G. Fosteri,* with much narrower lvs., which are narrowed gradually from the middle to a very narrow base. Green color as in *G. nivalis.* Bulb ½in. thick: lvs. whitish beneath:

outer segms. oblong, 9 lines long, 3–4 lines broad; stamens more than half as long as the inner segms. Mt. Taurus, in Cilicia, where it flowers Nov. to March. Intro. 1898. See G.C. III. 21:214. Pictured in G.C. III. 23:79. A.F. 13:1137. Gng. 6:244. F.E. 11:282. Gt. 48, p. 228. Gn. 73, p. 88.

BB. *Width of lvs. medium, 6–9 lines long.*

C. *Foliage moderately glaucous.*

D. *Outer segms. of perianth 12–15 lines long.*

3. **Imperàti,** Bertol. Lvs. broader than in *G. nivalis*, and fls. larger: outer corolla-segms. spatulate, 1–1¼ in. long. Naples and Genoa. This and *G. caucasicus* are regarded by Baker as subspecies of *G. nivalis*. G.C. II. 11:237. G.M. 34:155. Gn. 76, p. 119.

DD. *Outer segms. 9–12 lines long.*

4. **caucásicus,** Baker (*G. Redoùtei*, Rupr.). Lvs. finally 8–9 in. long, mostly 9 lines broad: outer perianth-segms. oblong-spatulate, with a very narrow claw; fls. later than *G. nivalis*. Caucasus. Van Tubergen seems to catalogue var. *máximus* of this species, but consult No. 11.

CC. *Foliage very glaucous.*

D. *Inner segms. with lobes rather spreading or crisped.*

5. **Élwesii,** Hook. GIANT SNOWDROP. Fig. 1616. Bulb larger and fls. more globose than in *G. nivalis:* outer segms. oblong-spatulate, 9–15 lines long, 6–9 lines broad; inner segms. green in the lower half and also around the sinus. Mountains of Asia Minor. B.M. 6166. R.H. 1880, p. 148. G.C. II. 11:236. G.M. 34:154. Gn. M. 2:117; 12:112.—The inner segms. are narrowed suddenly just below the apical lobes, which are square and much larger than in *G. Fosteri*. They also form a narrower tube than in any other species. Dealers have advertised vars. **Cassàba** (A. F. 3:471. C.L.A. 5:135. Gng. 5:180. Gt. 48, p. 225. Gn. 55, p. 206), **ochrospìlus** (has pale yellow coloring on the inner segms.), **unguiculàtus** has a long claw at the tip of each outer segm. (G.C. III. 17:361), and **Erìthræ.** Var. **globòsus** has almost globular fls., larger than in the type, and very broad lvs. Var. *Whíttallii* (Gn. 57, p. 45; 59, p. 262) seems to belong here. Var. **poculifórmis,** a large and robust form with the inner and outer segms. both pure white. Perhaps not in Amer. and rare in England.—*G. robustus*, Hort., seems never to have been accounted for by Baker. It may perhaps be *G. Elwesii* var. *robustus* which is a trade name. It is broad-lvd. and glaucous.

DD. *Inner segms. with lobes not spreading or crisped.*

6. **græcus,** Orph. Very near *G. Elwesii*, but differing as above and in the smaller fls. and narrower outer segms., and the very limited distribution of the wild species. April. Chios.

BBB. *Width of lvs. greatest, 9–12 lines.*

C. *Green color only near the sinus.*

D. *Colored on both sides of the inner segms.*

7. **latifòlius,** Rupr. Bulb. 1 in. thick: lvs. lorate, bright green: outer segms. oblong-spatulate, 6–9 lines long; inner segms. green around the sinus, inside and out; anthers suddenly narrowed to a sharp point, while in *G. nivalis* and *G. Elwesii* they are gradually narrowed. Caucasus, where it flowers in May. G.C. II. 11:237; 15:404. Gt. 48, p. 229.

DD. *Colored on only one side.*

8. **Ikàriæ,** Baker. Resembles *G. Fosteri* in foliage, and *G. Elwesii* not in coloring but in the square, crisp lobes of the inner segms. which tend to recurve: outer segms. nearly 1 in. long; stamens rather shorter than the inner segms.; green color occupying half the outside of the inner segms. Island of Nikaria (the classical Ikaria). See G.C. III. 13:506. Gn. 52, p. 361; 49, p. 330. G. 30:153. G.M. 52:146.—Intro. 1893.

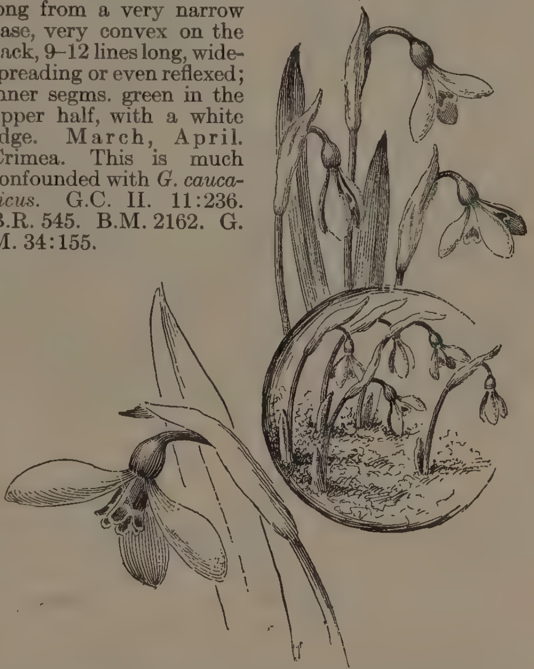
CC. *Green color also on the lower half of the inner segms.*

9. **Fósteri,** Baker. Resembles *G. latifolius* in foliage and *G. Elwesii* in fl., but the apical lobes of the inner segms. are short and erect, and smaller than in *G. Elwesii;* also the stamens are not more than half so long as the inner segms., while in *G. nivalis, G. Elwesii* and *G. latifolius* they are three-fourths as long. Asia Minor. Intro. 1889. G.M. 34:154. G. 35:193.

AA. *Lvs. plaited, the edges permanently rolled back.*

B. *Green color only near the sinus.*

10. **plicàtus,** Bieb. Bulb larger than in *G. nivalis:* lvs. about 12 in. long, and 1 in. wide, very glaucous: outer perianth-segms. oblong from a very narrow base, very convex on the back, 9–12 lines long, wide-spreading or even reflexed; inner segms. green in the upper half, with a white edge. March, April. Crimea. This is much confounded with *G. caucasicus*. G.C. II. 11:236. B.R. 545. B.M. 2162. G. M. 34:155.



1616. Galanthus nivalis and G. Elwesii. The upper flowers are G. nivalis; the lowest one is G. Elwesii; the middle flowers are a variety of G. Elwesii.

11. **grandiflòrus,** Baker (*G. máximus*, Baker, not Velenovsky). Possibly a hybrid between *G. plicatus* and some form of *G. nivalis*, remarkable for its robust habit and green color, extending more than half way down toward the base of the inner segms. Intro. 1893. See G.C. III. 13:354, 656. See also *G. caucasicus* var. *maximus*, No. 4.

BB. *Green color also on the lower half of the inner segms.*

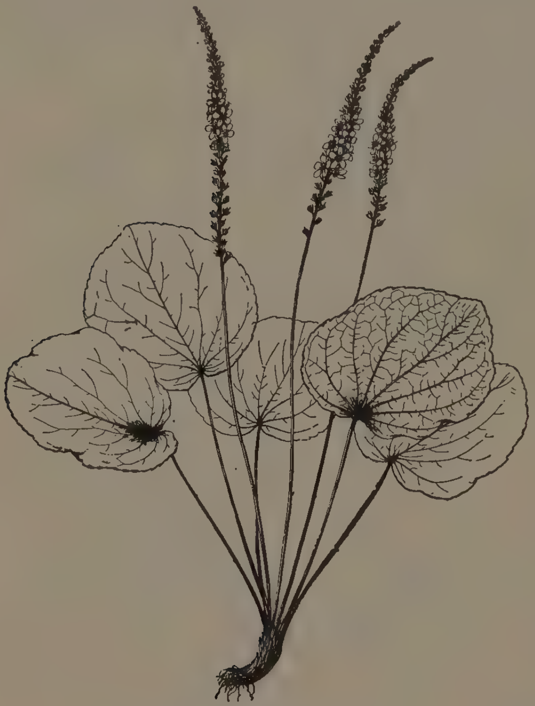
12. **byzantìnus,** Baker (*G. Gótwaldii*, Hort.). Intermediate between *G. plicatus* and *G. Elwesii*. "Lvs. 3 in. broad," which seems hardly possible, glaucous on both sides, especially beneath; margins distinctly and permanently recurved: outer segms. oblong, convex on back, 9 lines long, 4 lines broad, apical lobes somewhat reflexed and crisped; stamens much shorter than inner segms. Intro. 1893. See G. C. III. 13:226.

G. Állenii, Baker, has cone-shaped fls., pure white, but the petals "crimped into a distinctly large, horseshoe-like patch of green just below the wavy fold of the tips." Gn. 67, p. 53.—*G. Átkinsii*, Hort. Two plants seem to be cult. under this name, according to S. Arn., one a pure white one, the other frequently has an additional perianth-segm., also misshapen blooms. Both are scarcely known outside of England. Gn. 74, p. 154. By some supposed to be a form of G. nivalis.—*G. Ólgæ*, Orph. Outer segms. about 1 in. long; inner ones half as long, plain white, with rounded lobes. Blooms in Oct. Greece.—*G. Reginæ-Ólgæ*, Hort.=G. Olgæ.

WILHELM MILLER.
N. TAYLOR.†

GÀLAX (from the Greek meaning *milk;* application obscure). *Diapensiàceæ.* One acaulescent plant, much prized for its stiff bronzy root-leaves.

Calyx imbricated, persistent; petals 5, hypogynous, oblong-spatulate, entire, adnate to the base of the monadelphous stamens; the stamen-tube 10-toothed, the 5 teeth alternating with the petals antheriferous, the others petaloid; anthers transversely dehiscent; pistil 1; ovary superior, 3-celled, many-ovuled; style short: fr. a loculicidal, 3-valved caps.; seeds with a loose cellular testa.—This genus contains but a single species. It belongs to a small family which was much more extensive in past geologic times, but is now on the way to extinction. A large industry has arisen in recent years consisting in the marketing of immense quantities of galax lvs. for decorative purposes, especially at Christmas time; but the lvs. are also used at other times in wreaths and bouquets. The bronzy autumn coloration of the lvs. adds to their attractiveness. They are collected in the mountains of N. C. and Va. The plants are grown also in rockeries. It is recommended to plant in rockeries with northern exposure, shade, and some moisture. Prop. by division.



1617. Galax aphylla. (×½)

aphýlla, Linn. (*Blandfòrdia cordàta,* Andr.). GALAX. Fig. 1617. Evergreen, perennial herbs: rootstock thick, matted, creeping: lvs. basal, tufted, round-heart-shaped, with narrow sinus, crenate, shining, conspicuously palmately netted-veined, 1–3 in. broad, on long slender petioles: scape 1–2½ ft. high; spike-like raceme dense, 2–5 in. long; fls. small, white, 1½–2 lines broad. In dry woods chiefly in the mountains, Va. to Ga., and along the coast, Va. to N. C. B.M. 754. G.F. 5:605 (adapted in Fig. 1617). G.M. 44:223. Gn. 59, p. 187.—Called also colts-foot or beetle-weed.

K. M. WIEGAND.

Galax leaves were used for decorative purposes in a commercial way only as far back as 1890, when they were introduced to the northern florist trade by the writer, who had experimented with them for several years before that date, sending to hospitals and individuals. The reports received fully justified the introducer in advertising the leaf widely as a florist's decorative material for making up wreaths, crosses, and in fact all designs for which ivy leaves up to that time had been employed almost exclusively. Today galax leaves have to a great extent taken the place of ivy leaves, being less expensive, more easily handled and kept, and furnishing long wiry stems. The brilliant bronze leaves supply a color long needed in this class of work. The sizes also of the leaves vary from ½ inch or less to 5 inches diameter, again making their uses very varied. Small green galax leaves are now used extensively for bunching with violets, taking the place of the violet leaves. One of the features of the holiday season in Boston is the fakir with his stand of violets bunched with green galax. They come in again and are used the same way at the first touch of spring, when the early trailing arbutus or "mayflower" appears on the street. They can be arranged to cover much more space than the ivy leaves, and do not have to be wired, as is the case with the latter. The keeping qualities of galax are remarkable, and they are now used the year round from cold storage. Outdoor designs, as in cemeteries, will keep fresh and bright for months if not dried out, but otherwise require no care. A favorite arrangement of galax leaves is to place them loosely in a small vase, where they will retain their bright colors and shape for weeks, even in a close warm room, though most of the leaves are used, commonly with flowers, in designs made up by the florist. As a Christmas decoration they stand preëminent, and their general good qualities mentioned above cause them to be used throughout the year, more, perhaps, than any other decorative green, ferns possibly excepted.

In Philadelphia, some time ago, an enterprising young woman introduced a novel and taking innovation in the shape of potted galax plants for society dinners. Small, brilliantly colored green and bronze leaves were arranged in tiny pots, specially designed by Messrs. Sackett & Company, and placed at each plate, to be carried away by the guests as souvenirs. They were also sold through one of Philadelphia's leading merchants by thousands.

The larger cities, Boston, New York, Philadelphia and Chicago, use the largest quantities, though many of these are retailed again to smaller cities and towns all over the United States and Canada, and there is a large export trade now established in them, mostly to Germany and the Netherlands.

The area over which galax is collected extends from Virginia to Georgia, and is so vast that there is no danger of exterminating the plant by collecting the leaves, even if they were injured thereby, which does not seem to be the case. It is not practicable to grow the plants for the harvest of leaves, at least in America, the process being too expensive. Under cultivation they would perhaps not average one perfect salable leaf to a plant, as a speck or wormhole renders the leaf unfit for decorative purposes. In Europe galax has been tried with varying success under glass, the leaves bringing a very high price.

Galax aphylla is a beautiful ground-covering plant, specially adapted to the rhododendron border, where the soil and situation alike are suitable to its growth; it delights in shade and a cool, moist, peaty loam. Its charms are far better known in England, however, than at home. The leaves, when full grown, are always bright green, the brilliant bronze shades appearing later when the plant ripens and the frosts begin. Then when they are exposed to the direct rays of the sun the alternating freezing and sun action cause the leaves to turn in a short time, though sometimes this occurs to an extent before any freezing weather, when the sap starts downward. In dense shade they always remain green. In spring, when the sap begins to start, the leaves often turn green or dingy again, and eventually die down the second season.

HARLAN P. KELSEY.

GÁLBANUM: *Gums and Resins.*

GALEÁNDRA (Greek for *helmet* and *stamen*). *Orchidàceæ*, tribe *Vándeæ*. Deciduous epiphytes, to be grown under warmhouse conditions.

Plants with jointed thickened sts.: lvs. distichous, membranaceous: labellum infundibuliform; sepals and petals equal, spreading; column erect, winged; pollinia 2.—Six species in Trop. Amer. Cult. as for Eulophia.

Devoniàna, Lindl. St. erect: lvs. linear-lanceolate, sheathing at base: sepals and petals lanceolate, reddish brown, with green margins; labellum whitish, veined in front with crimson. From the banks of the Rio Negro. B.M. 4610. I.H. 21:176. A.F. 6:609. J.F. 2:195. V.O. 9:8.

Baùeri, Lindl. Sts. subcylindric, nearly fusiform: lvs. lanceolate: racemes terminal, drooping; fls. large; sepals and petals similar, lanceolate, yellowish; labellum pale yellow in the throat, interior portion purplish. Mex., S. B.R. 26:49. P.M. 14:49.

D'Escagnolleàna, Reichb. f. Sts. terete, tapering both ways: lvs. lanceolate, pointed: racemes terminal and drooping; sepals and petals similar, ascending, narrow, yellowish; lip funnelform or nearly bell-form, fluted, with a rose-purple blotch on the lower limb. Brazil. I.H. 34:22 (1887).

G. nivàlis, Mast. Racemes short, few-fld., fls. about 2 in. across; sepals and petals light olive-green, the funnel-like lip white with a purple blotch. Trop. Amer. V.O. 9:9. G.W. 14, p. 307.

Oakes Ames.
George V. Nash.†

GALEDÙPA: *Pongamia.*

GALÈGA (Greek, *gala*, milk: supposed to increase the flow of milk). *Leguminòsæ.* Bushy perennials not very commonly cultivated in America.

Of 120 names of species in this genus, only 6 are now retained, most of the others being referred to Tephrosia. The plants mentioned below are hardy herbaceous perennials of the easiest cult., about 3 ft. high, with odd-pinnate lvs. and pea-shaped fls. of purplish blue or white. They do not require frequent division, make bushy plants, and bear in July and Aug. many dense, axillary and terminal racemes of fls., which are useful for cutting. Seeds of goat's rue are still offered abroad among miscellaneous agricultural seeds, but the plants are little known in this country. They are native in S. Eu. and W. Asia.

A. *Lfts. lanceolate: stipules broadly lanceolate.*

officinàlis, Linn. Goat's Rue. Fig. 1618. Height 2–3 ft.: lfts. mucronate: fls. purplish blue. Eu., W. Asia. G.M. 49:57. Var. **álba** or **albiflòra** is commoner in cult. Gn. 50, p. 269. G.L. 22:294. J.H. III. 48:557. Var. **Hártlandii,** Hort., has large spikes of lilac fls. and the young foliage variegated. A.F. 22:695.—A rose-colored variety is sold as var. **cárnea,** Hort., which is also known in a double-fld. form; a dwarf, compact, lilac-fld. variety sold under the name var. **compácta,** is also known.

AA. *Lfts. lanceolate: stipules broadly ovate.*

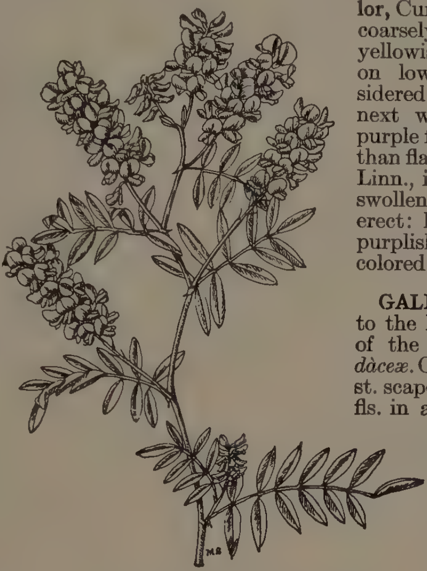
orientàlis, Lam. Foliage and stipules larger: fls. purplish blue, nodding: pods pendulous. Caucasus. B.M. 2192. Gn. W. 23:147. B.R. 326.—Height 2½–4 ft.: rootstock creeping: st. simple.

N. Taylor.†

GALEÓBDOLON: *Lamium.*

GALEÓPSIS (*weasel-like*, from some fancied resemblance). *Labiàtæ.* Hemp Nettle. Several weedy European plants, some of them naturalized in this country, rarely cult. in gardens. Annuals, of spreading habit, opposite lvs. that are dentate or entire, and red, yellowish or variegated fls. in whorls toward the top of the st.: calyx with 5 nearly equal teeth; corolla widened in the throat, bearing an entire arched upper lip and a palate with 2 teeth. **G. Ládanum,** Linn., is canescent, with very narrow, nearly or quite entire lvs.: fls. rose-red or red, sometimes spotted yellow: 8–12 in.: there are forms with broader lvs. and also narrow lvs., and otherwise variable. **G. versícolor,** Curt., has hispid sts., ovate coarsely toothed lvs., and large yellowish fls. with purple spot on lower lip: by some considered to be a form of the next with larger yellow-and-purple fls. and an arched rather than flat upper lip. **G. Tetràhit,** Linn., is bristly-hairy with st. swollen beneath the joints, erect: lvs. ovate, toothed: fls. purplish or white or particolored.

L. H. B.



1618. Galega officinalis. (×¼)

GALEÓRCHIS (in reference to the hood-like organ formed of the united sepals). *Orchidàceæ.* Orchids with fleshy roots: st. scape-like, with 2 basal lvs.: fls. in a short, loose spike, exceeded by the large bracts; sepals united, forming a hood; petals connivent; lip entire, spurred; column short; pollinia granulose, 1 mas in each sac, tailed.

spectábilis, Rydb. (*Órchis spectábilis*, Linn.). Showy Orchis. St. up to 1 ft. tall, 5-angled: spike 3–6-fld.; fls. violet-purple, variegated with lighter purple and white. N.E. N. Amer.

George V. Nash.

GALÌUM (Galion was the name of a plant mentioned by Dioscorides as used in curdling milk. *G. verum* is locally used abroad for this purpose). *Rubiàceæ.* Bedstraw or Ladies' Bedstraw, so-called because of the legend that one of these plants was in the hay on which the mother of Christ rested. Mostly weak or slender herbaceous plants with square, often barbed stems, and whorled leaves.

Flowers very small, perfect, epigynous; calyx almost or quite obsolete; corolla gamopetalous, rotate, deeply 4-parted; divisions in our species acute or acuminate; stamens 4; ovary inferior, 2-celled, forming a 2-lobed, 2-seeded, dry, indehiscent fr.; the lobes nearly globular.—About 220 species in various parts of the world. Noted for the recurved-scabrous sts. of many species, mathematical habit due to the whorled lvs., and the fine fluffy fls. The profuse-flowering species noted below are often used in rockeries and flower-beds for the regular but soft and filmy effect, which is similar to that of gypsophila. As cut-fls., they are used to lighten the effect of heavier fls.

A. *Fls. yellow.*

vèrum, Linn. Yellow Bedstraw. Perennial from a somewhat woody base: sts. erect, smooth, tufted, 1–3 ft. high: lvs. in 8's or 6's, linear, ½–1 in. long; apex bristle-tipped: panicle ample, its lower branches exceeding the lvs. Eu., now also a weed in fields in the E. U. S.—A very good plant for rockeries and banks.

AA. *Fls. white.*

B. *Lvs. in 4's, lanceolate, several-nerved.*

boreàle, Linn. Northern Bedstraw. Perennial, stoloniferous, forming patches: sts. smooth, 1–3 ft.

high, erect, strict: lvs. ¾–1½ in. long; apex not bristle-tipped: panicle ample: fr. usually minutely bristly. Rocky soil, Que. to Alaska and south to Pa. and Colo.—Useful in rockeries and flower-beds.

BB. *Lvs. in 8's or 6's, oblanceolate to linear.*

Mollùgo, Linn. Wild Madder. White or Great Hedge Bedstraw. Perennial, smooth: sts. erect or diffuse, 1–3 ft. high, mostly in clumps: lvs. ½–1 in. long, bristle-tipped, 1-nerved: panicle ample: fr. smooth. Eu., but a weed in fields in the eastern states.—This plant is known in some places as "baby's breath," but this name is properly given to gypsophila.

K. M. Wiegand.

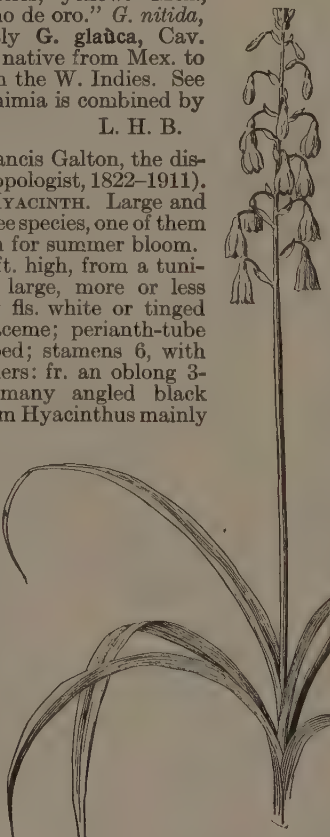
GALPHÌMIA (anagram of Malpighia). *Malpighiàceæ.* Woody plants, sparingly introduced in Florida and southern California.

Shrubs or subshrubs: lvs. opposite, small, slightly glaucous on both sides or beneath, entire or obscurely toothed, glandular at the margin or base of blade or at the tip of the lf.-stalk: clusters terminal; fls. yellow or reddish; calyx without glands; petals toothed, clawed, spreading: fr. a 3-parted caps., not winged.—Species 15 or more, from S. Texas to Brazil, largely Mexican. Little known as cult. plants, although a few species have been mentioned in hort. literature abroad, and the two following are listed in Calif. **G. brasiliénsis,** A. Juss. Shrub: lvs. ovate or lanceolate, about 1 in. long, reddish, glabrous, glaucous beneath: fls. small, yellow, in short lax panicles, said to be bright in winter in Calif.; pedicels jointed at base; petals ovate-lanceolate, obtuse, scarcely twice longer than calyx. Brazil. **G. hirsùta,** Cav. Shrub: lvs. bright green, ovate, acute, twice larger than in preceding, hairy both sides: fls. larger, in longer panicles, yellow. Mex., where it is known as "ramo de oro." *G. nitida,* cult. in Fla., is apparently **G. glaùca,** Cav. (*Thryállis glaùca,* Kuntze), native from Mex. to Panama and naturalized in the W. Indies. See *Thryallis,* with which Galphimia is combined by recent students.

L. H. B.

GALTÒNIA (after Sir Francis Galton, the distinguished author and anthropologist, 1822–1911). *Liliàceæ.* Giant Summer Hyacinth. Large and handsome Cape bulbs, of three species, one of them being cultivated in the open for summer bloom.

Scape or peduncle, 2–4 ft. high, from a tunicated bulb: lvs. long and large, more or less fleshy, all from the crown: fls. white or tinged green, large, in an open raceme; perianth-tube short, oblong or club-shaped; stamens 6, with linear-oblong versatile anthers: fr. an oblong 3-valved caps., containing many angled black seeds.—The genus differs from Hyacinthus mainly by its more numerous and flattened crowded seeds. The other 2 species are inferior to the following, which was intro. by Leichtlin in the early seventies of last century, and now holds a permanent place in horticulture. The plants prefer a rich, open, moist soil.



1619. Summer hyacinth, Galtonia candicans.

cándicans, Decne. (*Hyacinthus cándicans,* Baker). Fig. 1619. Bulb large, round, coated: lvs. 4–6, lorate-lanceolate, 2½ ft. long: scape often 4 ft. high; racemes 20–30-fld.; fls. fragrant, pure white, 1–1½ in. long, the tube oblong; stamens about ½in. long, inserted high in the tube. F.S. 21:2173. G.C. 1871:380, desc.; 1872:1099; II. 15:273. G. 28:687. Gn. 62, p. 361; 64, p. 158; 69, p. 163. J.H. III. 45:262; 47:583. R.H. 1882, p. 32. P.G. 3:101. A.G. 17:281. —The plants should be heavily mulched if left outdoors where winters are severe. In favored localities the bulbs may be left for several years with increasingly better results. Large clumps are desirable.

G. clavàta, Baker. Bulb ovoid, 3–4 in. diam.: lvs. 6–8, soft, 2–2½ ft. long, with whitish margin: scape 2 ft., bearing a lax raceme; fls. with a clavate tube which is 1 in. long and which is twice as long as the segms. B.M. 6885.—*G. princeps,* Decne. Much like G. candicans, but fls. fewer and raceme shorter: stamens inserted below middle of tube.

L. H. B.†

GAMÓGYNE (name refers to the united ovaries). *Aràceæ.* Two erect small herbs from the Malaysian region, bearing attractive colored inclined spathes: lvs. narrow, thickish, tapering into petiole: spadix included in the spathe: fls. apetalous; anthers truncate; ovaries united. *G. púlchra,* N. E. Br. Peduncles erect, terete, reddish brown, about 6 in. long: spathe bright crimson, about 1¾ in. long, spreading or almost nodding, closed except at top: stigmas red: spadix with neuter organs at base. B.M. 8330. *G. Búrbidgei,* N. E. Br. Spathe less brightly colored: stigmas greenish yellow: spadix with neuter organs between the male and female parts.

GAMÓLEPIS (Greek for *united scales;* referring to the involucre). *Compósitæ.* Flower-garden plants.

Leaves alternate and mostly pinnatisect: peduncles 1-headed, the heads bearing 1 series of yellow, pistillate rays, the disk-fls. perfect: achenes without pappus, wingless and glabrous.—About a dozen S. African herbs or small shrubs, somewhat allied botanically to Chrysanthemum.

Tagètes, DC. (*G. ánnua,* Less.). Fig. 1620. Annual, of wiry growth, a foot or less high, much branched and very floriferous: lvs. pinnate or pinnately parted, 5–7 lobes or lfts. on either side of the rachis and lfts. entire or lobed: involucre nearly or quite urn-shaped, the scales joined more than half their length; fls.-heads bright yellow or orange, ¾in. across. R.H. 1896, p. 412. Gn. 25, p. 407 (both as *G. Tagetes*).—Hardy or half-hardy. Of easiest cult. from seeds in sunny places, and most excellent for ribbon borders and for low mass effects. Continuous bloomer.

L. H. B.

GARCÌNIA (Laurence Garcin, who lived and collected in India, and wrote in the eighteenth century). *Guttiferæ.* This genus includes the mangosteen, which is declared by some connoisseurs to be one of the most luscious of all tropical fruits; also the gamboge tree, whose resinous juice yields a well-known pigment and purgative.

Garcinia is a polymorphous genus of upward of 150 species in the tropics of Asia, Africa and Polynesia. The species are glabrous trees, usually with a yellow juice: lvs. evergreen, opposite or ternate, simple, often thick: fls. solitary or fascicled, polygamous or diœcious; sepals and petals 4; stamens in male fl. many, 2- or 3-delphous; female fls. with staminodia; ovary 2- to many-celled, with sessile stigma and solitary ovule in each cell.—The mangosteen is cultivated in the West Indies; the gamboge tree is also cult. in S. Fla.; it is a broad-leaved tree of slow growth. The mangosteen is about the size and shape of an orange, with a rind of similar thickness and edible segments of form and arrangement like those of an orange. It is brilliantly colored outside with rich purple. The flavor is said to suggest something between a grape and a peach. Numberless efforts are said to have been made to naturalize this tree in the tropics without success. The successful ripening of this fruit under glass may be regarded as an achievement. See *Mangosteen.*

Mangostàna, Linn. MANGOSTEEN. Height 20–30 ft.: lvs. 7–10 in. long, elliptic-oblong, acuminate, leathery, nerves horizontal and very numerous: fls. (male) 1½ in. diam., purple or yellow-red, in few-fld. terminal fascicles; sepals orbicular, and petals broad-ovate and fleshy: fr. about 2½ in. diam., dark purple with large flat seeds. Malay region. B.M. 4847. L. B.C. 9:845. F.S. 22:2359. G.C. II. 4:657. G.W. 3, p. 8.

Morélla, Desr. GAMBOGE TREE. Height 30–50 ft.: lvs. more tapering at both ends, 4–6 in. long, the veins indistinct: fls. yellowish, male fls. about 3 in the axils, the sepals very small; female fls. larger, solitary, the staminodes about 12: fr. resembling a Morello cherry in size, slightly 4-lobed. Bengal to Siam.

L. H. B.†

1620. Gamolepis Tagetes. A good yellow-fld. composite for edgings. (×⅔)

GARDEN and GARDENING. The word garden etymologically means an inclosed space, and gardening is historically distinguished from agriculture by being within an inclosure of some kind instead of in the open fields. Gardening operations are usually conducted on a smaller scale than those of agriculture and by more intensive methods. Gardening and horticulture are really synonymous terms, but, by usage, a horticulturist is supposed to have a more extended training and wider range of activities than a gardener. Moreover, the word gardening now suggests more of the private, homelike and personal point of view, whereas the most distinctive feature of American horticulture is the immense commercial importance of fruit-growing on a large scale, and a marked emphasis of the professional side of a fruit-grower's work; and in later years, it is marked also by the very extensive vegetable-gardening and floricultural development. The history and discussion of gardening are, therefore, set forth in this book under *Horticulture.* Large private places are often divided into fruit-garden, kitchen-garden and flower-garden. Fruit-growing (which see) is the same as pomology. Kitchen-gardening, in its widest sense, is the same as vegetable-gardening (which see), or the more learned word, olericulture; but the expression kitchen-gardening is now less common, and usually indicates the private and uncommercial point of view, whereas market-gardening and truck-gardening (which are practically the same) are now the chief words used for the wholesale and commercial side of vegetable-gardening in the United States. Flower-gardening, a third primary division of gardening, is the same as floriculture (which see). Under ornamental gardening and landscape gardening are explained the two different points of view in the use of plants and flowers for their own separate values or when grouped for artistic effects, the nature-like or picturesque conception being set forth under landscape gardening, and the artificial or merely decorative styles under ornamental gardening.

It is customary to speak of gardening as the amateur and personal practice of horticulture. One makes a garden. One derives from the garden not only the plants and products that may be harvested, but also the satisfactions in plant-growing, the reaction to forms, fragrances and colors, and the gain of close contact with the out-of-doors. The first garden that one may have should be personal, for his own growth and development. Naturally, this will be in some personal or retired part of the grounds. In recent years, however, there has been a marked socialization of gardening, making it a contribution to public cleanliness and beauty and a means of educating the people. In America, this application of the gardening spirit to civic improvement has been very marked, as evidenced in the taking away of fences between adjoining properties and the development of a street as a unit. This is a great gain to public spirit and to social feeling; but this in no way interferes with the personal garden for the sheer love of it, to be grown in a place all one's own.

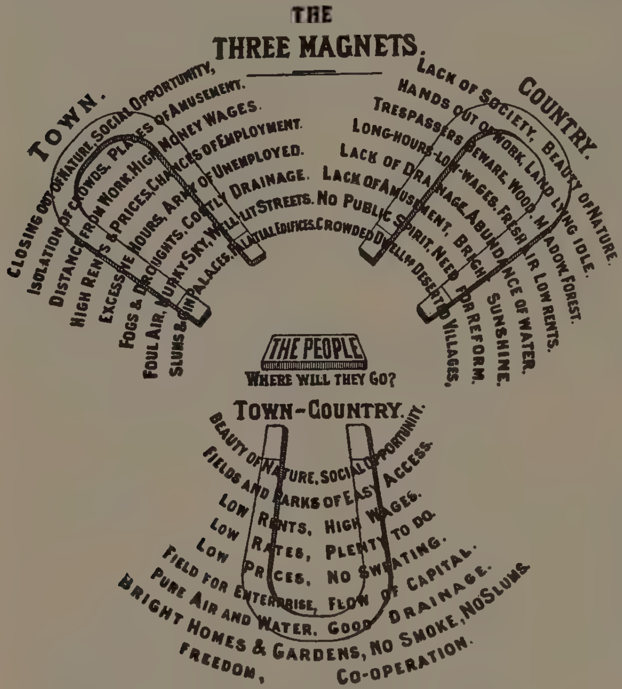
Persons desiring to find advice on specific gardening matters, should refer to the different genera under their respective heads; also to the articles under *Landscape Gardening,* and to such cultural entries as *Alpine Plants, Annuals, Arboriculture, Autumn Gardening, Banks, Bedding, Biennials, Border, Bulbs, Evergreens, Ferns, Herbary, House-plants, Orchids, Palms, Perennials, Rock-Gardening, Shrubbery, Spring-Gardening, Subtropical Gardening, Succulents, Vegetable-Gardening, Wall-Gardening, Water-Gardening, Kitchen-Garden, Wild-Garden,* and others.

L. H. B.

GARDEN CITIES. Instead of being a community in which gardens are the dominant feature, the garden-city form of urban dwelling-place implies primarily an industrial town of limited size and of definitely advanced economic ideals. While there were in England, where the idea originated, several prior developments, the example which has best typified the aims and practicability of the garden city is that sometimes known as Letchworth, but actually named Garden City, in Hertfordshire, about thirty-five miles from London. The genesis of this enterprise appears to have been in the reception given to a little book entitled "To-morrow: A Peaceful Path to Real Reform," issued in 1898, and written by Ebenezer Howard, then a London stenographer. The stated purpose was "to organize a migratory movement of population from our over-crowded centers to sparsely settled rural communities." In detail, Howard proposed "to find for our industrial population work at wages of higher purchasing power, and to secure healthier surroundings and more regular employment. To enterprising manufacturies, coöperative societies, architects, engineers, builders and mechanicians of all kinds, as well as to many engaged in various professions, it is intended to offer a means of securing new and better employment for their capital and talents, while to agriculturists it is designed to open a new market for their produce close to their doors. Its object is, in short, to raise the standard of health and comfort of all true workers of whatever grade, the means by which these objects are to be achieved being a healthy, natural and economic combination of town and country life, and this on land owned by the municipality." It will be observed that this is not a proprietary enterprise.

Howard considered that people aggregated themselves into the cities because of the "attractions" there, of various kinds. In the nature of the case, certain magnets attract to the town or city, and certain other magnets attract to the country. He would combine these magnets into a town-country habitation. He expressed the idea in a chart, Fig. 1621.

The reception given to this idea was so favorable that in 1902 a corporation was organized "to promote and further the distribution of the industrial population upon the land upon the lines suggested in Ebenezer Howard's book," which in 1904 began operations. It is interesting to note that among the subscribers to this company's stock were George Cadbury and Sir W. H. Lever, both of whom had previously established with success industrial villages upon a proprietary plan—Bournville and Port Sunlight.



THE
THREE MAGNETS.
TOWN.
Closing out of Nature, Social Opportunity,
Isolation of Crowds, Places of Amusement.
Distance from Work. High Money Wages.
High Rents & Prices, Chances of Employment.
Excessive Hours, Army of Unemployed.
Fogs & Droughts, Costly Drainage.
Foul Air, Murky Sky, Well-lit Streets.
Slums & Gin Palaces. Palatial Edifices.
COUNTRY.
Lack of Society, Beauty of Nature.
Hands out of Work, Land lying idle.
Trespassers beware, Wood, Meadow, Forest.
Long-hours-low-wages. Fresh Air. Low Rents.
Lack of Drainage. Abundance of Water.
Lack of Amusement, Bright Sunshine.
No Public Spirit, Need for Reform.
Crowded Dwellings, Deserted Villages,
THE PEOPLE
Where will they go?
TOWN-COUNTRY.
Beauty of Nature, Social Opportunity.
Fields and Parks of Easy Access.
Low Rents, High Wages.
Low Rates, Plenty to do.
Low Prices, No Sweating.
Field for Enterprise, Flow of Capital.
Pure Air and Water, Good Drainage.
Bright Homes & Gardens, No Smoke, No Slums.
Freedom, Co-operation.

1621. The three magnets that Mr. Howard considers to be the attractions for the people.

While it is not the province of this sketch to discuss in detail the sociological features either of Garden City in England, or of its German prototype at Hellerau, near to and dependent upon the great German enterprise of the Krupps at Essen, it is proper to report the steady growth of the Letchworth scheme (so called because of the name of the largest estate purchased for establishing the Garden City), and to note the removal thither of several large industries, of which it is said that "printing, book-binding and various branches of engineering are the chief industries, and there are at least a dozen others." Garden City had, in 1912, eight years from its beginning, a population of 7,912, scattered comfortably and working happily in 1,761 buildings in the developed part of its 4,500 acres, and the effect of living eight years in its designed wholesomeness had been to give it a death rate of eight in the thousand, as compared with 14.1 for the larger English communities from which it drew its inhabitants and its industries. It is quite within the scope of this book to register the sober conclusion of the Royal Commission on Canals and Inland Navigation (England), in 1909, that "If industries are widely distributed, workers can have better houses at lower rents, can breathe less vitiated air, and they and their families can in many cases combine with factory work the healthy and profitable work of small agricultural production."

"The gardens of Garden City are . . . the small individual gardens of its houses and cottages. . . . The garden is inevitable in Garden City. . . . You will not find a house without one—a real practical garden. . . . The majority keep their gardens well. . . . Most of the residences are detached, with gardens all around them." Such are comments on this feature of the successful Garden City found in a book on the enterprise, itself an evidence of the quality of the printing product of the community. (The Garden City, by C. B. Purdom; "printed in the Garden City at the Temple Press and published by J. M. Dent & Sons, Ltd., London, 1913.")

In addition to the prevalence of gardens, this industrial community enjoys other features not usual in hit-or-miss development. The houses in Garden City are not in blocks or "rows," are not monotonously similar, include careful provision for health and cleanliness, and range in cost from $1,000 to more than $10,000. There are many outdoor recreational facilities, and a strong community spirit helps to provide entertainment and amusement. The town plan takes account of the contour of the land, and the houses of whatever character are touched or approached by the green of vine or tree or plant.

In the United States there are as yet no garden cities so thoughtfully designed and so capably worked out. There is a "Garden City" near New York, but it is merely a well-handled real estate promotion enterprise. Pullman near Chicago, was an attempt at mitigating the rigors of the congested city, and Gary, in Indiana, is a later and slightly more advanced industrial town. Neither approximates the efficiency of the English example. There are building in northern Michigan several industrial towns in which there is both planting and the retention of some native growth, but these are proprietary enterprises, and not coöperative as is the Letchworth Garden City.

It is certain that there will come into existence many more communities of the type of Garden City, because it is coming to be generally known that the influences of the garden and of wider living areas upon an industrial population are economically favorable and tend to contentment, permanence and prosperity, especially if intoxicating liquors are either kept out or are made available only under sharp restraint.

J. Horace McFarland.

GARDÈNIA (after Alexander Garden, M.D., of Charleston, S. C., a correspondent of Linnæus). *Rubiàceæ.* Shrubs or rarely small trees, sometimes nearly or quite evergreen, some of which are planted South and one yields popular flowers for cutting.

Plants glabrous or pubescent or even tomentose: lvs. opposite or in 3's, with interpetiolar stipules: fls. large, axillary and solitary or sometimes corymbose, yellow or white; calyx-tube ovoid or obconic; corolla salver-shaped or tubular, the tube much exceeding the calyx, the limb with 5–9 spreading or recurved contorted lobes; stamens 5–9, on the corolla-throat.—Species about 60, in subtropical regions of the eastern hemisphere. See *Randia* for related plants.

Gardenia includes the Cape jasmine, a tender shrub 2 to 6 feet high, with thick, evergreen foliage and large double, waxy camellia-like, fragrant flowers. It

XLVI. Type of an old-time formal garden.—Washington's garden at Mt. Vernon.

blooms from May to September in the South, where it is often used for hedges, and is hardy as far north as Virginia. In the middle of last century the Cape jasmine was considered one of the finest stove shrubs in cultivation, but with the waning popularity of camellias the doom of the Cape jasmine as a conservatory plant was sealed. The camellia has a greater range of color, and has had hundreds of varieties, while its scented rival has had barely a dozen. The flowers of the Cape jasmine have never been so perfectly regular as those of a camellia, and the plants are very subject to insect enemies. Their bloom is successional rather than close, and large plants are therefore not so showy as camellias. They are considerably grown abroad for cut-flowers in early spring, young plants a season or two old being used for best results. The variety with variegated foliage is dwarfer and weaker-growing. The true botanical name of the Cape jasmine is *G. jasminoides*, a name almost never used in the trade. "Cape jasmine" itself is one of the most remarkable cases of the vitality of an erroneous popular name. The single-flowered form was introduced much later than the double, and has always been less popular. The earliest picture of a living plant with single flowers was published in 1820 in B. R. 449. Cape jasmines are also handled by importers of Japanese plants, who sometimes offer seeds also. *G. lucida* was probably introduced by Reasoner, and *G. Rothmannia* by Franceschi, who reports that it is probably not now (1914) in cultivation. For the true jasmines (which belong to the olive family, and are often trailing plants), see *Jasminum.*

Culture.—The Cape jasmine of today, *Gardenia Veitchii*, was introduced by the well-known English firm of Jas. Veitch & Son. This new variety has fulfilled the long-desired want, because it is really a winter-flowering variety, while the old species *Gardenia jasminoides* or *G. florida* could not be made to flower during the early and midwinter when actually most valuable, hence the almost total abandonment of that old variety for cut-flower purposes. This new type has become one of the most popular florist flowers, although it is one of the most difficult plants to handle. The young plants are raised from cuttings in the early winter. Care must be taken to propagate only from thoroughly healthy plants. Three- to four-eye cuttings should be put into clean, sharp sand with a minimum bottom heat of 70° and a maximum of 85°. The atmosphere should be rather close in the propagating-house until after the cuttings begin to root, then some air should be admitted. The cutting-bench must be kept shaded from the sun and frequent syringing is absolutely necessary. When fully rooted in the sand, they are potted into 2-inch pots in well-prepared soil of four parts decomposed sod loam, one part of well-rotted old cow-manure and one part sand. The soil should be well screened. Potting firmly is essential, and not too much room should be left for water. A gentle bottom heat for these young plants is highly beneficial. When the sun begins to get higher and the days lengthen, a little fresh air during the middle of the day is invigorating for the young plants, but the night temperature should never go below 65°. The plants must be kept growing constantly and should be repotted as soon as they have filled their pots with roots. The months of May and June are the best time to plant gardenias into benches or solid beds. The best soil has been found to be well-rotted turf or sod, a pliable loam and well-rotted cow-manure well mixed, three parts of loam to one of manure. Should the soil be rather stiff or of a heavy texture, a portion of sand may be added. The benches should be 4 to 5 inches deep and have sufficient openings or cracks for drainage. Where very thin turf or sod can be had, the bench should be lined with this, or if not practicable, then a layer of sphagnum moss so as to cover the bottom of the bench. On top of this, a liberal sprinkling of pieces of charcoal will tend to keep the soil sweet. A small quantity of ground bone may be sprinkled over the soil after it is all spread on the benches ready for planting. Care must be taken that all balls are well softened and dissolved when planting so that there will be an amalgamation of the new soil and the soil of the ball. Firm planting and immediate watering are of the highest importance and frequent syringing after planting. Shading is not necessary, providing frequent syringing is given. Keep the soil moist but never wet. It is well to keep the house rather close for a few days, after which air can be given freely. *Gardenia Veitchii* can stand any amount of heat, and there is no danger of burning or scorching until the foliage begins to get warm. When thermometer goes above 90° to 95° more air must be given. The plants must now make their growth and if buds appear they must be pinched out. Keep pinching out buds and small side shoots until the latter part of September when buds may be allowed to set upon the stronger shoots. A strong healthy plant can carry four to six such flowering shoots. After buds begin to set and sometimes even before, bottom shoots begin to come. These are the second growth and make for a second crop of flowers as well as for propagating the young plants for the next season. Plants are seldom kept over the second year although it can be done successfully. Young plants are decidedly the most profitable. When the plants are well set with buds, in October and November, and the roots appear on the surface, a very light mulch of cow-manure is beneficial as it will assist to develop the flowers. A night temperature of 65° to 68° is best, while during the day it may range from 70° to 90°. Good hard syringing will keep down the pests which are fond of this plant, especially the mealy-bug. The flowers should be cut before the center petals have fully expanded and the longer the stem the more valuable the flower. (H. A. Siebrecht.)

A. *Corolla-tube cylindrical.*

B. *Calyx with 5 long teeth.*

C. *Ribs on the calyx.*

jasminoìdes, Ellis (*G. flórida,* Linn. *G. radìcans,* Thunb.). CAPE JASMINE. Variable, very small shrub, unarmed, the st. sometimes rooting: lvs. lanceolate, sometimes variegated: fls. white, solitary, very fragrant, waxy. For pictures of double forms, see B.M. 1842 and 2627, and B.R. 73; single, B.R. 449 and B.M. 3349; normal and variegated foliage, R.H. 1864, p. 30. China. Var. **Fortuniàna,** Lindl. (*G. Fórtunei,* Hort.). B.R. 32:43. F.S. 2:177. R.B. 23:241. In 1893 was advertised *G. camelliæflòra* in addition to *G. radìcans*, *G. flórida* and vars. *màjor* and *majéstica. G. sinénsis grandiflòra* of Berger's catalogue perhaps belongs here. Presumably the *G. Veitchii* of the gardens belongs here.

CC. *Ribs not present.*

lùcida, Roxbg. Buds resinous: lvs. oblong; stipules annular, variously divided at the mouth, unequally lobed: fls. stalked, fragrant, white but ultimately turning yellow, 1–2½ in. across. India, Burma, Luzon. —The calyx-teeth are not decurrent, as in the Cape jasmine, and thus the calyx does not have the ribbed look.

BB. *Calyx tubular, with 5 very short teeth.*

amœna, Sims. Differs from all here described in having numerous strong spines nearly ½in. long, which are axillary: lvs. oval, acute, short-stalked: fls. subterminal; corolla-tube 1 in. long, longer than the lobes, which are 6, obovate, white, with margins incurved enough to show the rosy back. India or China.

BBB. *Calyx spathe-like.*

Thunbérgia, Linn. f. Lvs. broadly elliptic, acute, with pairs of glands along the midribs: fls. 3 in. across, pure white; corolla-lobes 8, overlapping. S. Afr. B.M. 1004.—Dwarf-growing, and perhaps not now in cult. in this country.

AA. *Corolla-tube short and wide-throated.*

B. *Fls. 3 in. long and broad.*

Rothmánnia, Linn. f. Very distinct in foliage and fl.: lvs. with pairs of hairy glands along the midrib: calyx ribbed, with 5 long teeth, equaling the short, cylindrical portion of the corolla-tube; corolla-tube rather suddenly swelled, ribbed; lobes 5, long-acuminate, whitish, spotted purple in the mouth. S. Afr. B.M. 690. L.B.C. 11:1053.—Fls. pale yellow, but it does not bloom in Calif. according to Franceschi.

BB. *Fls. 1½ in. long and broad.*

globòsa, Hochst. Lvs. oblong, short-acuminate; lf.-stalk nearly 3–5 lines long: fls. white, inside hairy and lined pale yellow; calyx small, with 5 very short teeth; corolla-tube wide at the base and gradually swelled; lobes 5, short-acuminate. S. Afr. B.M. 4791. F.S. 9:951.

G. citriodòra, Hook.=Mitriostigma axillare.—*G. intermèdia,* Hort., is a name unknown in botanical literature and the plant's affinities are unknown.—*G. Stanleyàna,* Hook.=Randia maculata.

Wilhelm Miller.
N. Taylor.†

GARDEN LEMON: *Cucumis Melo.*

GARDÒQUIA BETONICOÌDES: *Cedronella mexicana.*

GARGET: *Phytolacca decandra.*

GARLAND FLOWER in the South sometimes means *Hedychium coronarium.* Often means *Daphne Cneorum.*

GARLIC (*Állium satìvum,* Linn.). Hardy perennial bulbous plant, closely allied to the onion. It is native of southern Europe. It has flat leaves, and the bulb is composed of several separable parts or bulbels, called cloves. These cloves are planted, as are onion sets, in spring or in fall in the South. They mature in summer and early autumn, being ready to gather when the leaves die away. If the soil is rich, it may be necessary to break over the tops to prevent too much top growth and to make the bulbs better, as is sometimes done with onions. This is done when the top growth has reached normal full size. The cloves are usually set 4 to 6 inches apart in drills or rows, in ordinary garden soil. The bulbs are used in cookery, but mostly amongst the foreign population. Strings of bulbs braided together by their tops are common in metropolitan markets (Fig. 1622). The bulbs are white-skinned or sometimes rose-tinged.

L. H. B.

1622. Garlic, as strung for market.

GARLIC PEAR: *Cratæva.*

GÁRRYA (after Nicholas Garry, secretary of the Hudson Bay Company). Including *Fadyénia. Garryàceæ,* formerly included under *Cornàceæ.* Ornamental shrubs chiefly grown for foliage and showy catkins.

Evergreen: lvs. opposite, short-petioled, entire or denticulate, without stipules: fls. diœcious, apetalous, 1–3 in the axils of opposite bracts on elongated, often drooping, axillary spikes; staminate fls. with 4 sepals and 4 stamens; pistillate with 2 sepals and 2 styles and a 1-celled ovary: berry 1–2-seeded, rather dry.—About 10 species in W. N. Amer. from S. Ore. to S. Mex., east to W. Texas.

The garryas generally have elliptic to oblong leaves, and small greenish white or yellowish flowers in catkin-like, often pendulous spikes, and dark purple or dark blue berries. None of the species is hardy North but *G. flavescens, G. Wrightii,* and also *G. Fremontii,* which are the hardiest, can probably be grown north to New York in sheltered positions, while the others are hardy in warmer regions only. They are well adapted for evergreen shrubberies, and the staminate plants are especially decorative in early spring with the showy, pendulous catkins, which in *G. elliptica* attain to 1 foot in length and often bloom in midwinter. The garryas thrive well in a well-drained soil and in sunny, sheltered position; in England they are often grown on walls. Propagation is by seeds or by cuttings of half-ripened wood under glass; also by layers.

ellíptica, Douglas. Shrub, to 8 ft.: lvs. elliptic to oval-oblong, obtuse or acute, usually undulate, glabrous above, densely tomentose beneath, 1½–3 in. long: 3 fls. in the axils of short and broad, pointed bracts; spikes rather dense, staminate 2–12 in. long often branched, pistillate 1–3 in. long: fr. globose, silky tomentose. Calif. to New Mex. B.R. 1686. Gn. 33, p. 562; 37, p. 501; 39, p. 261; 51, p. 257; 53, p. 449; 55, p. 258; 57, p. 122; 63, p. 181; 67, p. 149; 76, p. 639. G.C. II. 22:425; III. 35:42, 43. Gn. W. 22:115. G. 20:30; 35:21. H.U. 2, p. 35. H.F. 1865: 198. G.L. 24:190.—This is the handsomest species, and stands about 10° of frost (sometimes more) in a sheltered position.

G. Fadyénii, Hook. (Fadyenia Hookeri, Griseb.). Shrub, to 15 ft.: lvs. elliptic to oblong, acute or mucronulate, glossy above, tomentose beneath or almost glabrous at length, 2–4 in. long: bracts oblong-lanceolate, remote: fr. tomentose. Jamaica, Cuba.—*G. flavéscens,* Wats. (G. Veatchii var. flavescens, Coult. & Evans). Shrub, to 8 ft.: lvs. elliptic, silky pubescent below, 1–2 in. long: spikes dense, about 1 in. long. Ariz., Utah, N. Mex.—*G. Fremóntii,* Torr. Shrub, to 10 ft.: lvs. ovate to oblong, acute, glabrous on both sides, yellowish green, 1–3 in. long: spikes dense, 2–5 in. long: with short bracts: fr. pedicelled, glabrous. Ore. to Calif. G.C. II. 15:431; III. 35:44.—*G. macrophýlla,* Benth. Shrub, to 6 ft.: lvs. ovate to oblong-ovate, glabrous above, villous-pubescent beneath, 2–5 in. long: spikes dense and short: fr. sessile. Mex.—*G. Thurétii,* Carr. (G. elliptica × G. Fadyenii). Shrub, to 15 ft.: lvs. elliptic to elliptic-oblong, whitish tomentose beneath, 2–5 in. long: bracts remote, with usually 1 fl. in each axil; spikes shorter than those of G. elliptica. Originated in France. R.H. 1869, p. 17; 1879, pp. 154, 155.—*G. Vèatchii,* Kellogg. Spreading shrub, to 8 ft.: lvs. elliptic-ovate to ovate-oblong, acute, yellowish green, tomentose beneath, 1½–2½ in. long: spikes dense, 1–2 in. long: fr. sessile, usually silky tomentose. Nev. to Calif. and N. Mex. Named for J. A. Veatch, botanical explorer of Cedros Isl., Lower Calif.—*G. Wrìghtii,* Torr. Shrub, to 10 ft.: lvs. elliptic or elliptic-ovate, acutish and mucronate, glabrous or nearly so below, 1–2 in. long: spikes slender, about 2 in. long: fr. glabrous, nearly sessile. Ariz., Mex.

Alfred Rehder.

GARÙGA (native East Indian name). *Burseràceæ.* This includes a deciduous East Indian tree, reaching 60 feet, and cultivated in southern Florida and California for its fruits, which are the size of a gooseberry, and are eaten raw, but chiefly pickled.

Tomentose or hairy plants: lvs. crowded at tips of branches, alternate, odd-pinnate; lfts. opposite, subsessile, serrate: fls. polygamous, large, panicled; calyx bell-shaped, 5-cut; petals 5, inserted on the tube of the calyx above the middle; stamens 10; ovary 4–5-celled; ovules in pairs: drupe with 5, or by abortion 1–3, stones, which are wrinkled and finally 1-seeded.—Species perhaps a dozen in India and Pacific islands to Austral.

pinnàta, Roxbg. Tree, 30–40 ft., with lvs. 1 ft. or more long; lfts. obtusely crenate: fls. small, in a very large panicle: fr. a black drupe. India and Malaya to the Philippines.—Also cult. abroad under glass.

L. H. B.

GAS PLANT: *Dictamnus.*

GASTÈRIA (Greek, *gaster*, belly; referring to the usually swollen base of the flowers). *Liliàceæ*, tribe *Aloíneæ.* Mostly acaulescent and small succulents of similar decorative uses and treatment as Aloe.

Leaves usually elongated, crowded in rosettes or on short sts., usually 2-ranked: fls. with a red or rosy typically ventricose curved tube and short equal suberect greenish segms. about as long as the stamens and pistil. S. Afr. Species 43. Monog. by Berger in Engler, Das Pflanzenreich, hft. 33 (1908).

A. *Fls. scarcely 1 in. long, mostly ventricose.*

B. *Lvs. radical, in 2 nearly straight ranks, not keeled.*

C. *The lvs. with pale raised warts.*

1. **verrucòsa,** Haw. (*Alòe verrucòsa,* Mill. *A. dísticha,* Linn. *A. verrùcula,* Medikus. *A. acuminàta* and *A. racemòsa,* Lam.). Cespitose: lvs. acute, somewhat concavely 3-sided, spreading, ½ x 4–6 in., dull gray, very rough with white crowded tubercles: infl. 2 ft. high, typically simple. Cape. B.M. 837. DC., Pl. Gr. 63. Berger 42, 43.—Varies in a form with lvs. 1 ft. long and branched infl., var. **latifòlia,** Salm (*Alòe lingua* var., Ker), B.M. 1322, f. 2, 3. Salm, Aloe § 29, f. 25; a form with large greener more mucronate lvs. with less crowded warts, var. **intermèdia,** Baker (*G. intermèdia,* Haw. *Alòe intermèdia,* Haw.), Salm, Aloe § 29, f. 24. B.M. 1322, f. 1; and a form with scarcely concave greener lvs. with the greenish warts somewhat in lines on the back, var. **scabérrima,** Baker (*G. intermèdia scabérrima,* Haw. *Alòe scabérrima* Salm), Salm, Aloe § 29, f. 26. Hybrids are reported between *G. verrucosa* and *G. pulchra; G. verrucosa intermedia* and *G. carinata* as well as *Haworthia radula;* and *G. verrucosa latifolia* and *G. brevifolia.*

CC. *The lvs. not white-warty.*

2. **conspurcàta,** Haw. (*G. dísticha conspurcàta,* Baker. *Alòe conspurcàta,* Salm). Lvs. obtuse, mucronate, little concave, 1½ x 10–12 in., green, smooth except on the margin, with small often confluent white spots: infl. 2½–3 ft. high, simple. Cape. Salm, Aloe § 29, f. 31.

3. **angulàta,** Haw. (*G. dísticha angulàta,* Baker. *G. longifòlia,* Haw. *Alòe angulàta,* Willd. *A. lingua longifòlia,* Haw.). Lvs. abruptly short-mucronate, a little concave on one or both faces, 2 x 8–10 in., one or both edges angularly doubled, dark green with small often confluent white spots: infl. 3 ft. high, exceptionally branching. Cape(?). Salm, Aloe § 29, f. 29.—A form with gutter-like lvs. is var. **truncàta,** Berger (*A. angulàta truncàta,* Willd.).

4. **sulcàta,** Haw. (*G. angulàta,* Haw. *Alòe sulcàta,* Salm. *A. lingua angulàta,* Haw.). Lvs. concavely strap-shaped, 4-angled, 1 x 4 in., dull green with small greenish little-raised dots: infl. 2 ft. high, simple; fls. little inflated. Cape. Salm, Aloe § 29, f. 32.

5. **língua,** Berger (*G. dísticha,* Haw. *G. denticulàta,* Haw. *Alòe lingua,* Thunb. *A. dísticha,* R. & S.). Lvs. obtusely mucronate, oblong, somewhat concave, 2-edged, denticulate above, 2 x 8–10 in., green or grayish with more or less banded and pale greenish spots: infl. 3 ft. high, simple. Cape. Salm, Aloe § 29, f. 33. Berger 44.

6. **nígricans,** Haw. (*Alòe nígricans,* Haw. *A. oblìqua,* Jacq.). Lvs. oblong, abruptly mucronate, 2-edged, 2 x 5–8 in., glossy dark green or purplish with more or less banded pale greenish spots: infl. 3 ft. high, sometimes branched. Cape. Salm, Aloe § 29, f. 7.—Varies into a less mottled form with shorter fleshier lvs., var. **crassifòlia,** Haw. (*A. lingua crassifòlia,* Ait. *A. crassifòlia,* R. & S.), B.M. 838. J.H. III. 60, p. 98; and a white- and rosy-marbled form with smaller lvs., var. **marmoràta,** Baker (*A. marmoràta,* Salm. *A. formòsa,* R. & S.).

7. **subnígricans,** Haw. (*G. nígricans subnígricans,* Baker. *Alòe subnígricans,* Spreng. *A. pseudonígricans,* Salm). Lvs. scarcely 1 in. wide, acute, green with small separate rather transversely arranged pale spots: infl. 3 ft. high, simple; fls. ventricose. Cape. Salm, Aloe § 29, f. 10.—Varies into a form with more concave lvs., var. **canaliculàta,** Salm; and a form with sword-like darker lvs., var. **glàbrior,** Haw. (*Alòe guttàta,* Salm. *A. nígricans denticulàta,* Salm. *G. nígricans guttàta,* Baker). Salm, Aloe § 29, f. 9.

BB. *Lvs. crowded along an evident if short st.*

C. *The lvs. in 2 straight or twisted ranks.*

8. **planifòlia,** Baker (*Alòe planifòlia,* Baker) Lvs. in straight ranks, narrow, abruptly mucronate, 2-edged, ¾ x 6–10 in., glossy green with more or less confluent oblong white spots, the minutely rough margin often rosy: infl. 6 ft. high, or more, simple; perianth very abruptly inflated below. Cape. Ref. Bot. 162.

9. **pícta,** Haw. (*Alòe Boureàna,* R. &. S., *A. Bowieàna,* Salm). Lvs. in twisted ranks, tongue-shaped, abruptly mucronate, somewhat concave and 3-sided, 1½–2 x 10–14 in., glossy dark green mottled with round white spots confluent below, the thickened margin subentire: infl. 3 ft. high, branched. Cape. Salm, Aloe § 29, f. 3.—Varies into the smaller var. **formòsa,** Berger (*Alòe Bowieàna formòsa,* Salm. *G. formòsa,* Haw.).

10. **maculàta,** Haw. (*G. oblìqua,* Haw. *G. nígricans platyphýlla,* Baker. *Alòe maculàta,* Thunb. *A. oblìqua,* Haw. *A. maculàta oblìqua,* Ait.). Lvs. in somewhat twisted ranks, tongue-shaped, blunt or abruptly mucronate, 2-edged or with one margin doubled, 1¾–2 x 6–8 in., glossy dark green with more or less confluent large oblong spots or entirely white at base below, rough-margined: infl. 3–4 ft. high, branched. Cape. Salm Aloe § 29, f. 1. B.M. 979. Berger 47.—Two varieties are distinguished: var. **fállax,** Haw. (*A. maculàta angústior,* Salm), with smaller whiter smooth lvs., and var. **Dregeàna,** Berger, with rough-margined lvs.

11. **púlchra,** Haw. (*Alòe maculàta púlchra,* Ait. *A. púlchra,* Jacq). Lvs. in spiral ranks, falcate, narrowed from the base, acute, scarcely 1 x 8–10 in., glossy dark green with oblong white spots transversely or reticulately confluent, slightly rough-margined: infl. 3 ft. high, branched. Cape. Jacq., Schoenbr. 4:19. Salm, Aloe § 29, f. 2. DC., Pl. Gr. 91. B.M. 765. Miller, Icon. 292. Berger 47.—It is said to have been crossed with *G. verrucosa.*

CC. *The lvs. not 2-ranked.*

12. **marmoràta,** Baker. Lvs. smooth, lorate-lanceolate, rounded and cuspidate at tip, 1–1½ x 5–6 in., with one margin doubled, dark green with large greenish more or less confluent spots: infl. 2–2½ ft. high. branched. Cape.

BBB. *Lvs. nearly radical, typically keeled or triquetrous.*

c. *The lvs. in 2 spiral ranks.*

13. **excavàta,** Haw. (*Alòe excavàta,* Willd. *A. obscùra,* Willd.). Lvs. smooth, rather thin, spreading, lanceolate, mucronately acute, denticulate, 1–1½ x 4–5 in., dull pale green with small greenish white spots: infl. 2 ft. high, simple. Cape. Salm, Aloe § 29, f. 22. B.M. 1322, f. 4.

cc. *The lvs. not 2-ranked.*

14. **parvifòlia,** Baker. Lvs. thick, deltoid-oblong, submucronate, somewhat roughened on keel and margin, 1 x 2–3 in., purplish green with small whitish spots: infl. 1½ ft. high, simple. Cape. Berger 49.

15. **carinàta,** Haw. (*Alòe carinàta,* Mill. *A. tristicha,* Medikus). Lvs. thick, spreading, triangular-lanceolate, somewhat falcate, acute from the 2-in. base, 5–6 in. long, grooved above, dull green with coarse whitish warts sometimes in irregular lines: infl. 2½–3 ft., sometimes branched. Cape. B.M. 1331*a*. Salm, Aloe § 29, f. 20. Berger 50.—Varies into a larger smoother form, var. **strigàta,** Baker (*G. strigàta,* Haw. *A. carinàta lævior,* Salm); a form with narrower more falcate lvs. with smaller pale points, var. **falcàta,** Berger; and a form with short broad still finer-punctate lvs., var. **latifòlia,** Berger. It is said to have been crossed with *G. verrucosa intermedia.*

16. **glàbra,** Haw. (*Alòe glàbra,* Salm. *A. carinàta subglàbra,* Haw.). Lvs. triangular-lanceolate, acute or mucronate from the 2-in. base, 6–8 in. long, dull green with small scarcely raised whitish points: infl. 2½–3 ft. high. Cape. Salm, Aloe § 29, f. 19. B.M. 1331, lf. at left.—Respectively larger and smaller forms are sometimes designated as vars. **màjor** and **mìnor.**

17. **nítida,** Haw. (*Alòe nítida,* Salm). Lvs. triangular-lanceolate, acute from the 2-in. base, 6–9 in. long, smooth, light glossy green with white often banded spots, the margin roughish: infl. 3 ft. high, simple. Cape. Salm, Aloe § 29, f. 17.—Varies in a form with more numerous smaller pale dots, var. **parvipunctàta,** Salm (*A. nítida màjor,* Salm). B.M. 2304; and one with fewer, larger and more confluent spots, var. **grandipunctàta,** Salm (*A. nítida mìnor,* Salm).

AA. *Fls. 1½–2 in., little inflated, long-stalked: large for the genus.*

18. **acinacifòlia,** Haw. (*Alòe acinacifòlia,* Jacq.). Lvs. acute, 3-edged, spreading in a large 2-ranked rosette, 2 x 14 in., rather glossy dark green with scattered low pale dots: infl. about 4 ft. high, branched below. Cape. B.M. 2369. Berger 52.—Varies in a more erect-lvd. form, var. **ensifòlia,** Baker (*G. ensifòlia,* Haw.), Salm, Aloe § 29, f. 12; a form with more confluent low mottling, var. **nìtens,** Baker (*G. nìtens,* Haw. *Alòe nìtens,* R. & S.); and a narrower-lvd. form with somewhat seriate slightly raised whiter spots, var. **venústa,** Baker (*G. venústa,* Haw. *Alòe venústa,* R. & S. *A. acinacifòlia venústa,* Salm). It has been crossed with *Aloe striata.*

G. brevifòlia, Haw. Lvs. 3–4 in. long, lingulate, close together: fls. red, about 1 in. long. Afr.—*G. Húttoniæ,* N. E. Br. Lvs. in a loose rosette, 16–18 in. long, broad at base, narrowed above, obliquely keeled: fls. pendulous, nearly 1 in. long, rose with green-keeled lobes. S. Afr.—*G. obtusifòlia,* Haw. Lvs. thinner than in G. sulcata and shorter than in G. lingua.

William Trelease.

GASTÒNIA PALMÀTA: *Trevesia.*

GASTROCHÌLUS (Greek-made name, alluding to the swollen lip). *Zingiberàceæ.* A very few Indian and Malayan herbs, perennial or annual, that may sometimes be found in choice collections of hothouse plants. Allied to Hedychium and Kaempferia, differing from the former in the character of the connective and from the latter in the sac-form lip: sometimes provided with a creeping rootstock: st. very short or none, or reaching 12 in. high: lvs. oblong and acute: fls. mostly white with lip yellow or pink, solitary or in spikes; corolla-tube slender and the segms. connivent; staminodia present and petal-like; lip oblong and entire but the margin sinuate, exceeding the corolla; ovary 3-celled, each cell many-ovuled. *G. pulchérrima,* Wall., is leafy-stemmed, to 12 in., from a creeping rootstock: fls. white in a spike 2–3 in. long, the lip tinged pink. H. U. 4, p. 100. *G. longiflòra,* Wall., is acaulescent, with lvs. to 12 in. long: fls. 1 or 2 from the crown, long-tubed, white, the lip tinged red. The Gastrochilus of Don is orchidaceous, and is now referred to Saccolabium.

L. H. B.

GASTROLÒBIUM (Greek-made name, referring to the swollen pods). *Leguminòsæ.* More than 30 shrubs of W. Austral., little known in cult. Lvs. simple and entire, mostly stiff: fls. yellow or in part purple-red, racemose in corymbs or whorls; calyx 5-lobed; petals clawed, the standard orbicular or kidney-shaped, and emarginate, the wings oblong, and the keel broad and short; stamens free; style filiform, incurved: pod turgid, ovoid or nearly globular. *G. velùtinum,* Lindl. A handsome shrub: lvs. in 3's or 4's, varying from obovate to linear-cuneate, very obtuse, emarginate, ¾in. or less long: fls. orange-red, on villous pedicels, in terminal clusters to 1½ in. long: pod ovoid, about ¼in. long. *G. cuneàtum,* Henfr., may be the same as the foregoing, perhaps with longer racemes. J.F. 3:258. *G. villòsum,* Benth. Decumbent with ascending sts.: lvs. opposite, ovate to almost lanceolate, very obtuse, 1–2 in. long: fls. in terminal pedunculate racemes 3–4 in. long; standard orange-red, shorter lower petals purple-red: pod broadly ovoid, about ⅓in. long. B.R. 33:45. J.F. 4:341. *G. ovalifòlium,* Henfr. Diffuse shrub: lvs. mostly opposite, ovate or oblong or orbicular, 1 in. or less long, often emarginate: fls. nearly sessile in racemes 1–3 in. long, orange or orange-red, the lower petals deeply colored. J.F. 3:247, 324.

L. H. B.

GASTRONÈMA: A section of *Cyrtanthus.*

GAULTHÈRIA (named by Kalm after Dr. "Gaulthier," a physician in Quebec, whose name was really written Gaultier). *Ericàceæ.* Ornamental woody plants grown for the attractive flowers and fruits and also for their handsome evergreen foliage.

Evergreen erect or procumbent shrubs, rarely small trees, usually hairy and glandular: lvs. petioled, roundish to lanceolate, mostly serrate: fls. in terminal panicles or axillary racemes or solitary; calyx 5-parted; corolla urceolate, 5-lobed; stamens 10; ovary superior: fr. a 5-celled, dehiscent caps., usually inclosed by the fleshy and berry-like calyx.—About 90 species in the warmer and subtropical regions of Asia, Austral., and in Amer. from Canada to Chile. Some have edible fruits, and an aromatic oil used in perfumery and medicine is obtained from *G. procumbens* and several Asiatic species.

This genus includes the wintergreen and some other ornamental low aromatic plants with alternate, evergreen leaves, white, pink or scarlet, often fragrant flowers in terminal or axillary racemes or solitary, and with decorative, berry-like red or blackish fruit. *G. procumbens* is fully hardy North, while the other North American species are somewhat tenderer and need protection during the winter; *G. Veitchiana* promises to be hardy as far north as Massachusetts. They are well adapted for borders of evergreen shrubberies as well as for rockeries, and in suitable soil they are apt to form a handsome evergreen ground-cover. Most of the foreign species can be grown only South or as greenhouse shrubs. They grow best in sandy or peaty, somewhat moist soil and partly shaded situations. Propagation is by seeds, layers or suckers, division of older plants, and also by cuttings of half-ripened wood under glass.

A. *Fls. solitary.*

procúmbens, Linn. Wintergreen. Checkerberry. Boxberry. Partridge Berry. St. creeping, sending up erect branches to 5 in. high, bearing toward the end 3–8 dark green, oval or obovate, almost glabrous lvs., 1–2 in. long, with ciliate teeth: fls. solitary, nodding; corolla ovate, white, about ¼in. long; anthers with 4 awns; filaments pubescent: fr. scarlet. July–Sept. Canada to Ga., west to Mich. B.M. 1966. L.B.C. 1:82. Gn. 31, p. 379.

AA. *Fls. in racemes.*

Shállon, Pursh. Low shrub, to 2 ft., with spreading, glandular-hairy branches: lvs. roundish-ovate or ovate, cordate or rounded at the base, serrulate, 2–4 in. long: fls. nodding, in terminal and axillary racemes; corolla ovate, white or pinkish: fr. purplish black, glandular, hairy. May, June; fr. Sept., Oct. Brit. Col. to Calif. Called "shallon" or "salal" by Indians. B.M. 2843. B.R. 1411. L.B.C. 14:1372. Gn. 31, p. 379.

Veitchiàna, Craib. Shrub, to 3 ft., sometimes decumbent: branchlets setose: lvs. elliptic to oblong or obovate-oblong, short-apiculate, broadly cuneate or nearly rounded at the base, setose-serrulate, glabrous and lustrous above, paler below and setose on the veins while young, 1½–3½ in. long: fls. in axillary and terminal villous racemes 1–2 in. long, densely bracteate, the bracts as long or longer than the pedicels; corolla ovate, white, ¼in. long: fr. indigo-blue. May, June; fr. Aug., Sept. W. China.

G. antípoda, Forst. Shrub, to 5 ft., sometimes procumbent, hairy: lvs. orbicular to oblong, ¼–⅛in.: fl. solitary, white or pink, campanulate. New Zeal., Tasmania.—*G. coccínea,* HBK. Shrub, to 2 ft., hairy: lvs. roundish ovate, about 1 in.: fls. slender-pedicelled, in elongated, secund racemes; corolla ovate, pink. Venezuela. R.H. 1849:181.—*G. ferrugínea,* Cham. & Schlecht. (G. ignescens, Lem.). Small shrub, rufously hairy: lvs. ovate or oblong, 1–2 in.: fls. almost like those of the preceding species. Brazil. B.M. 4697. J.F. 3:265; 4:371.—*G. fragrantíssima,* Wall. Shrub or small tree, glabrous: lvs. elliptic to lanceolate, 2½–3½ in. long: racemes axillary, erect, shorter than the lvs.; corolla white or pinkish, globular-ovate. Himalayas, Ceylon. B.M. 5984.—*G. myrsinìtes,* Hook. Allied to G. procumbens. Lvs. orbicular or broadly ovate, ½–1 in. long: corolla broadly campanulate; filaments glabrous; anthers without awns. Wash. to Calif. and Colo.—*G. nummularioìdes,* D. Don (G. Nummularia, DC.). Procumbent: branches densely rufously hairy: lvs. orbicular to ovate, ½–1 in. long: fls. solitary, ovate, white. Himalayas. G.C. II. 22:457.—*G. oppositifòlia,* Hook. f. Shrub, to 8 ft.: lvs. mostly opposite, ovate, cordate, bluntly toothed, 1½–2½ in. long: fls. white, urceolate, ⅙in. long, in terminal panicles 3–4 in. long. New Zeal. G.C. III. 52:109. Gn. 75, p. 412.—*G. ovatifòlia,* Gray. Procumbent, with ascending and sparingly hairy branches: lvs. ovate, acute, 1–1½ in. long: fls. solitary, campanulate: fr. scarlet. Brit. Col. to Ore.—*G. pyroloìdes,* Hook. f. & Thom. (G. pyrolæfolia, Hook. f.). Low shrub, sometimes procumbent, almost glabrous: lvs elliptic-obovate, about 1½ in. long: racemes few-fld., axillary. Himalayas, Japan. Var. *cuneàta,* Rehd. & Wilson. Branchlets minutely villous: lvs. narrow, oblong-obovate, cuneate: ovary and fr. villous. W. China.—*G. trichophýlla,* Royle. Dwarf: lvs. elliptic, ciliate, ⅙–½ in. long: fls. axillary, pinkish: fr. blue. Himalayas, W. China. B.M. 7635.

Alfred Rehder.

GAÙRA (Greek, *superb*). *Onagràceæ.* This includes several herbs which are distinct in appearance, but scarcely possess general garden value, although they are pleasant incidents in the hardy border for those who like native plants.

Annual, biennial or perennial plants confined to the warmer regions of N. Amer.: lvs. alternate, sessile or stalked, entire, dentate, or sinuate: fls. white or rose, in spikes or racemes; calyx-tube deciduous, obconical, much prolonged beyond the ovary, with 4 reflexed lobes; petals clawed, unequal; stamens mostly 8, with a small scale-like appendage before the base of each filament; stigma 4-lobed, surrounded by a ring or cup-like border: fr. nut-like, 3–4-ribbed, finally 1-celled, and 1–4-seeded.—Species 20–25. The bloom ascends the slender racemes too slowly to make the plants as showy as possible. The best kind is *G. Lindheimeri,* which has white fls. of singular appearance, with rosy calyx-tubes. Gauras are easily prop. by seed. They prefer light soils, and the seedlings can be transplanted directly into permanent quarters.

A. *Height 3 ft.: fls. white.*

Líndheimeri, Engelm. & Gray. St. hairy and more or less branched above: lvs. lanceolate or more often spatulate with a few wavy teeth and recurved margins: fls. in a loose spike. Texas and La. R.H. 1851:41; 1857, p. 262. H.F. 8:145. G.W. 14, p. 100.

AA. *Height 1 ft.: fls. rosy, turning to scarlet.*

coccínea, Nutt. An erect or ascending, usually much-branched perennial: lvs. numerous, lanceolate to linear or oblong, repand-denticulate or entire: fls. in spikes, very showy, except that the whole spike does not come into flower at one time: fr. 4-sided. Manitoba to Mont. and Texas.

Wilhelm Miller.
N. Taylor.†

GAÙSSIA (probably from a personal name). *Palmàceæ.* One slender pinnate-leaved palm, reaching about 20 ft., from Cuba, recently intro. in S. Calif. It is allied to Hyophorbe and Pseudophœnix. **G. prínceps,** Wendl., is a spineless species, the st. thickened below but very slender above: lvs. pinnatisect, the pinnæ crowded and narrow-linear and entire or 2-cut: fls. very small, on filiform branches, monœcious; spadix long-stalked: fr. small, purple or red.

L. H. B.

GAỲA (for Jacques and perhaps Claude Gay, writers on the plants of W. S. Amer.). *Malvàceæ.* About a dozen herbs, shrubs or small trees of S. Amer. except the one described below: mostly tomentose: lvs. usually undivided: fls. yellow or white, axillary or terminal, pedunculate, with no bracteoles; calyx 5-parted; staminal column split at apex into many parts; ovary many-celled and style-branches as many as the cells, the ovules 1 in each cell. *G. Lỳallii,* Baker (*Plagiánthus Lỳallii,* Gray), the lacebark, endemic in the southern island of New Zeal., is recorded in horticultural literature abroad. It is said by Cheeseman to be one of the most beautiful trees of the New Zealand flora, often forming a broad fringe to the subalpine beech forests. It is partly deciduous at high elevations, but is evergreen in certain river valleys. It is a small spreading tree 15–30 ft. high: lvs. ovate, acuminate, usually double-crenate, sometimes somewhat lobed: fls. to 1 in. diam., white, in axillary fascicles or rarely solitary; petals obliquely obovate, retuse. G.C. III. 50:56, and Suppl. Sept. 23, 1911. B.M. 5935.—Hardy in the south of England, where it blooms profusely.

L. H. B.

GAYLUSSÀCIA (after J. L. Gaylussac, eminent French chemist; died 1850). Syn., *Adnària.* *Ericàceæ,* tribe *Vaccínieæ.* Huckleberry. Small shrubs, some grown for their handsome flowers, others valued for their edible fruits.

Evergreen or deciduous: lvs. alternate, short-petioled, usually entire: fls. in axillary, usually few-fld. racemes; calyx 5-lobed, persistent; corolla tubular-campanulate or urceolate; stamens 10; anthers acute; ovary inferior, 10-celled, each cell with 1 ovule: fr. a berry-like drupe with 10 nutlets.—About 50 species in E. N. Amer. and S. Amer. Closely allied to Vaccinium, distinguished by the 10-celled ovary, each cell with 1 ovule.

The huckleberries are low shrubs with white, red, or reddish green flowers, and blue or black mostly edible fruits. The deciduous species are hardy North, but are of little decorative value, the handsomest being *G. dumosa,* while the evergreen species, all inhabitants of the South American mountains, except the half-hardy *G. brachycera,* are often very ornamental in foliage and flowers, but tender and hardly cultivated in this country. They grow best in peaty or sandy soil and in shaded situations; but *G. baccata* thrives well also in drier localities and exposed to the full sun; like other Ericaceæ, they are all impatient of limestone. Propagated by seeds, layers or division; the evergreen species by cuttings of half-ripened wood under glass. See also *Vaccinium* for cultivation.

A. *Lvs. evergreen, obtusely serrate.*

brachýcera, Gray. Low shrub, with creeping and ascending st. and spreading angled glabrous branches: lvs. oval, glabrous, ½–1 in. long: racemes short, with few white or pinkish fls.: fr. blue. May, June; fr. July, Aug. Pa. to Va. B.M. 928. L.B.C. 7:648 (as *Vaccinium buxifolium*).

AA. *Lvs. deciduous, entire.*

B. *Fls. in loose racemes; corolla campanulate.*

C. *Plant glandular-pubescent.*

dumòsa, Torr. & Gray. Shrub, to 2 ft., with creeping st. and almost erect, somewhat hairy and glandular branches: lvs. obovate-oblong to oblanceolate, mucronate, shining above, leathery, 1–2 in. long: fls. white or pinkish; bracts foliaceous and persistent: fr. black, usually pubescent, rather insipid. May, June; fr. Aug., Sept. Newfoundland to Fla. and La. in moist sandy or swampy soil. B.M. 1106 (as *Vaccinium*).

1623. Gazania splendens. (×½)

CC. *Plant slightly pubescent or glabrous.*

frondòsa, Torr. & Gray. Blue Huckleberry. Dangleberry. Tangleberry. Shrub, to 6 ft., with spreading, usually glabrous branches: lvs. oblong or oval-obovate, obtuse or emarginate, pale green above, whitish beneath, membranaceous, 1–2 in. long: fls. slender-pedicelled; corolla broadly campanulate, greenish purple: fr. blue, with glaucous bloom, sweet. May, June; fr. July. N. H. to Fla., west to Ky., preferring moist, peaty soil. Em. 2:451. G.C. III. 7:580.

ursìna, Torr. & Gray. Shrub, to 6 ft., with somewhat pubescent, spreading branches: lvs. obovate to oblong, acute, membranaceous, 2–4 in. long: fls. white or pinkish: fr. black, shining, sweet. May, June; fr. July, Aug. N. and S. C.—Harlan P. Kelsey writes of this species: "Shrub 2 to 6 feet high; very local in a few counties in southwestern North Carolina, though common in these stations. Locally it is known as 'buckberry,' a name given by the native mountaineers from the fact that deer feed on the very abundant clustered fruit in late summer. The berries are much used for pies and jams, and have a most peculiar and pleasant acid flavor, unlike any other Vaccinium. It promises to be a valuable addition to our garden fruits."

BB. *Fls. in short, sessile racemes; corolla ovate.*

baccàta, Koch (*G. resinòsa*, Torr. & Gray). Black Huckleberry. Erect shrub, to 3 ft., resinous when young: lvs. oval or oblong-lanceolate, mucronulate, yellowish green above, pale beneath, 1–1½ in. long: fls. short-pedicelled, nodding, reddish: fr. black, rarely white, sweet. May, June; fr. July, Aug. Newfoundland to Ga., west to Wis. and Ky., preferring sandy or rocky soil. Em. 451. B.M. 1288 (as Vaccinium). I.T. 4:152. Var. **glaucocárpa,** Rob. Frs. larger, blue with glaucous bloom.

G. Pseùdo-Vaccìnium, Cham. & Schlecht. Evergreen, usually glabrous shrub, to 3 ft., with elliptic, entire lvs. and red fls. in secund, many-fld. racemes. Brazil. B.R. 30:62. R.H. 1845:285

Alfred Rehder.

GAZÀNIA (after Theodore of Gaza, 1393–1478, translator of Aristotle and Theophrastus; by some considered to be derived from Greek, *riches*, owing to the splendid floral coloring). *Compósitæ.* Showy plants grown in a cool greenhouse or in the open border in summer.

Herbaceous, mostly perennial, rarely annual, with short sts. or none: lvs. crowded at the crown of the root, or scattered along the st.: involucral scales in 2 or several rows, cup-like at the base, toothed at the apex: achenes wingless, villous; pappus in 2 series of very delicate, scarious, toothed scales, often hidden in the wool of the achene.—Species 24–30. This group contains some of the finest of the sub-shrubby composites from the Cape of Good Hope. They have a wide range of color,—pure white, yellow, orange, scarlet, and the backs of the rays are in some cases rich purple, and even azure-blue. Their foliage is often densely woolly beneath, and the range of form is unusual. The group is also notable for the spots near the base of the rays of *G. Pavonia* and some others. These markings suggest the eyes of a peacock's tail. The plants are also remarkable for their behavior at night, when they close their fls. and turn their foliage enough to make the woolly under sides of the lvs. more conspicuous.

Gazanias are now rarely met with in some of the oldest-fashioned florists' establishments. Few of the more prominent firms keep them now, and they may be said to be practically out of the trade in America. All the kinds described below are old garden favorites abroad, particularly *G. rigens*, a common bedding plant, cultivated for nearly a century and a half, but whose precise habitat has never been ascertained. They are of easy culture in the cool greenhouse, and are commended for summer use in the borders of those who can keep them under glass in winter. They can be rapidly propagated in midsummer by cuttings made from the side shoots near the base and placed in a close frame.

A. *Color of heads yellow.*

B. *Rays not spotted: heads 2 in. across.*

unifiòra, Sims. Sts. woody at the base, spreading 6–12 in. or more from a center: lvs. varying as mentioned above. The woolliness also varies greatly: sometimes the whole plant is snowy white; sometimes the whiteness is confined to the under sides of the lvs. B.M. 2270. L.B.C. 8:795.—The involucre is woolly, according to Harvey, but the pictures cited do not show it. This and *G. rigens* have short sts. with branches alternately leafy, while *G. pinnata*, *G. Pavonia* and *G. pygmæa* have little or no st. and the lvs. radical or tufted at the ends of the short branches.

BB. *Rays spotted at base: heads 3 in. or more across.*

pinnàta, Less. Rootstock perennial, fibrous: lvs. commonly pinnate (some simple); lobes oblong or linear in several pairs; white on both surfaces and stiff-hairy: peduncle not much longer than lvs.; involucral scales acuminate, particularly the inner ones. Harvey names 6 botanical varieties.

AA. *Color of heads orange: rays spotted at base: heads 3 in. or more across.*

B. *Lvs. mostly entire and spatulate.*

C. *Basal markings containing brown.*

rìgens, R. Br. Sts. short and densely leafy or diffuse, laxly leafy, with ascending branches: lvs. sometimes sparingly pinnatifid, i. e., with only 1 or 2 side lobes, white beneath except on the midrib: heads large and showy, 1½ in. wide, the rays orange, disk purplish black. B.M. 90 (as *Gorteria rigens*) shows a head of scarlet rays, with basal markings of brown, black and white.

CC. *Basal markings without brown.*

spléndens, Hort. Fig. 1623. Hybrid, said to resemble *G. uniflora* in habit but dwarfer and more compact. Of the kinds in common cult. it is nearest to *G. Pavonia* in coloring of fls. H.F. II. 4:240.

BB. *Lvs. mostly pinnate.*

Pavònia, R. Br. PEACOCK GAZANIA. Involucral scales short, the inner broad, acute or subacute. B.R. 35 shows markings of brown, white, yellow and blue, which are marvelous in design and precision of execution.

AAA. *Color of heads white above.*

pygmæ̀a, Sond. Crown woody and much divided: lvs. spatulate, entire: rays white, striped purple beneath. Gn. 47:288. I.H. 43:53. B.M. 7455. G. 30:101. Var. **maculàta,** N. E. Br. Rays pale creamy white, with a blackish spot at the base, reverse striped dull purple. Var. **supérba,** N. E. Br. Rays white, unspotted, reverse striped bluish. Var. **lùtea,** Hort. Fl.-heads very large, chrome-yellow.—This species is very variable in its involucral scales, which may be short or long, sometimes cup-shaped at the base, and again almost free. This upsets one of the most important features of Harvey's key.

A hybrid between G. nivea, Less., and G. longiscapa, DC., known as *G. hýbrida*, has been described as a very profuse bloomer, flowering continuously from June to late autumn. R.H. 1900:209. Gt. 47:134.—*G. longiscàpa*, DC. (G. stenophylla, Hort.), is a white-woolly perennial with a glabrous peduncle which is shorter than the lvs.: involucre glabrous.—*G. nívea*, DC. Very dwarf, almost woody: lvs. crowded, hoary-tomentose on both sides: peduncle not exceeding the lvs.: involucre tomentose. Last two probably not cult. in Amer.

WILHELM MILLER.
N. TAYLOR.†

GEISSORHÌZA (Greek words alluding to the coats of the bulb, which cover it somewhat like overlapping tiles). *Iridàceæ.* Ixia-like half-hardy Cape bulbs, which are dormant from August to November and are usually flowered under glass in spring and early summer.

Cormous: lvs. few, distichous: fls. in different colors, in open, simple or forked spikes; perianth nearly regular, rotate, with a cylindrical tube; stamens 6, inserted in the throat; ovary 3-celled, becoming a small oblong caps.—Species about 30, 1 in Madagascar and the others in S. Afr. The genus has a wide range in habit and in color of fls., but these plants are presumably inferior to ixias for general culture. The following species are advertised.

rochénsis, Ker. Corm ¼in. diam., globular: lvs. 3, one of them on the st., glabrous, basal ones narrow, few-ribbed: st. 3–6 in., simple or forked, with 1 fl. at the top; st.-sheath loose and swelling: fls. violet-purple, 1–2 in. across; perianth-tube shorter than the spathe; segms. with a blotch at the base. B.M. 598, where the whole plant is a trifle over 3 in. high and the fls. purple, with a dark red eye, the latter surrounded by a pale blue circle.

hírta, Ker. Lvs. hairy: fls. 2–6 in a loose spike, bright red, the tube very short, segms. not blotched: corm ½in. diam., globular.—Offered in S. Calif. L. H. B.

GEITONOPLÈSIUM (Greek-made name, *near neighbor*, in allusion to its kinship to another genus). *Liliàceæ.* Woody stemmed twiners of Austral. and Pacific islands of probably 2 species; one is offered in S. Calif. Fls. small, in loose terminal clusters: lvs. alternate, linear to ovate, very short-stalked, lightly nerved; perianth with 6 oblong distinct segms., the 3 outer ones more or less hood-shaped at times, the inner ones flat and obtuse; stamens 6, included: fr. a nearly globular berry with thin pulp and becoming dry; seeds irregular, black. **G. cymòsum,** Cunn. Tall-climbing, with wiry sts.: fls. purplish green, the perianth ⅛in. or less long, the pedicels very short and jointed under the fl.: berry dark blue, ½in. or less diam.; seeds few. Queensland to Victoria. B.M. 3131. L. H. B.

GELSÈMIUM (from the word *Gelsemino*, the Italian name of the true jessamine). *Loganiàceæ.* Climbing shrubs, with evergreen foliage and yellow flowers.

Glabrous, twining, shrubby plants, with opposite, rarely whorled lvs., and showy, hypogynous, perfect, regular, yellow and very fragrant fls., in axillary and terminal cymes, the pedicels scaly-bracted: calyx imbricated, deeply 5-parted; corolla funnelform, 5-lobed, imbricated in the bud; stamens 5, epipetalous; ovary solitary, superior, 2-celled; ovules numerous, on narrow placentæ; style slender, 4-cleft: fr. an elliptic, septicidal caps., flattened contrary to the partition; valves boat-shaped, 2-cleft at the apex; seeds flattened and winged.—There are 2 species in the genus, one American the other Chinese. The American or Carolina yellow jessamine is a well-known woody twiner of the S., bearing evergreen foliage and a profusion of bright yellow, very fragrant fls. The cymes of the Chinese species are terminal and trichotomous. Our species is very desirable for covering banks and fences in any soil. It is also grown occasionally in conservatories. The rhizomes and roots are used medicinally as a nervine, antispasmodic and sedative. The true jessamine is *Jasminum officinale* (*Oleaceæ*) of Eu.

sempérvirens, Ait. f. CAROLINA YELLOW JESSAMINE. St. high-climbing: lvs. ovate, or lanceolate, shining, entire, short-petioled, 1–3 in. long: cymes terminal, 1–6-fld.; the fls. dimorphous; corolla 1–1½ in. long. Low woods and thickets, Va. to Fla., Texas and Guatemala; early flowering. B.M. 7851. G.W. 9, p. 494. K. M. WIEGAND.

GENÉTYLLIS: *Darwinia.*

GENÌPA (Brazilian name). *Rubiàceæ.* This includes a West Indian shrub allied to the Cape jasmine and barely known to American horticulture. Genipa and Gardenia are difficult to separate.

Small trees or shrubs: lvs. with short or no stalks, opposite, large, leathery, obovate or lanceolate, shining: cymes axillary, few-fld.; fls. white to yellowish; calyx-limb bell-shaped, truncated, or 5-toothed; corolla salver-shaped, limb twisted to the left, 5-parted; stigma club-shaped or bifid; ovary 1-celled; placentas 2, almost touching each other in the axis: berries edible.

clusiifòlia, Griseb. A shrub 4–10 ft. in the wild, not so large in cult.: lvs. 4 in. or less long, black when dried, obovate, glabrous: corymbs short-peduncled; calyx-limb 5-cut, the pedicels as long as the calyx; corolla glabrous, the tube nearly as long as the lobes: berry ovoid. W. Indies.

americàna, Linn. A small tree: lvs. 5–10 in. long, lanceolate-oblong, glabrous: pedicels shorter than the calyx; corolla silky, white, about 1 in. across: berry similar to last, but is "highly commended in cookery" according to Reasoner, by whom the plant was intro. (1914). W. Indies.—The fr. is largely used in Trop. Amer. as a preserve under the name "genipop." It is often used as a kind of marmalade and has been called "marmalade-box" in Surinam. N. TAYLOR.†

GENÍSTA (ancient Latin name). *Leguminòsæ.* Ornamental woody plants chiefly grown for their handsome yellow, rarely white, flowers.

Deciduous or half-evergreen, sometimes nearly leafless shrubs, unarmed or spiny: branches usually striped and green: lvs. alternate, rarely opposite, entire, simple or sometimes 3-foliolate: fls. papilionaceous, in terminal racemes or heads, rarely axillary, yellow, rarely white; calyx 2-lipped, with the upper lip deeply 2-parted; style incurved: pod globular to narrow-oblong, 1- to many-seeded, dehiscent, rarely indehiscent.—About 100 species in Eu., Canary Isls., N. Afr. and W. Asia. Allied to Cytisus, but without callose appendage at the base of the seeds. The Genista of florists is Cytisus.

The genistas are ornamental, usually low shrubs with showy flowers, appearing profusely in spring or summer, and followed by small, insignificant pods. None of the species is quite hardy North, but *G. tinctoria, G. pilosa, G. germanica* and some other European species will do well in a sheltered position or if somewhat protected during the winter, while the others are more suited for cultivation in southern regions. They are essentially plants suited to drier climates and most of them do well in California. They are adapted for covering dry, sandy banks and rocky slopes, and for borders and rockeries. They grow in any well-drained soil, and like a sunny position. Propagate by seeds, sown in spring, also by layers and by greenwood cuttings under glass.

A. *Color of fls. white.*

1. **monospérma,** Lam. (*Retàma monospérma,* Boiss.). Shrub, to 10 ft. or more with slender grayish branches, almost leafless: lvs. small, simple or rarely 3-foliolate, generally linear or linear-spatulate, silky: fls. white, fragrant, in short lateral racemes; corolla silky; calyx purple: pod broadly oval, 1–2-seeded. Feb.–April. Spain, N. Afr. B.M. 683. B.R. 1918. Gn. 55, p. 213; 62, p. 15. G.W. 15, p. 412.

AA. *Color of fls. yellow.*

B. *Twigs striped, not winged.* (Nos. 2–15.)

C. *Pod globular, indehiscent, 1-seeded.*

2. **sphærocárpa,** Lam. Similar to the preceding, but lower and more upright, leafless: fls. yellow, very small, in numerous panicled racemes; corolla glabrous. May, June. Spain, N. Afr.

CC. *Pod oval to linear, dehiscent.*

D. *Shrubs spiny.*

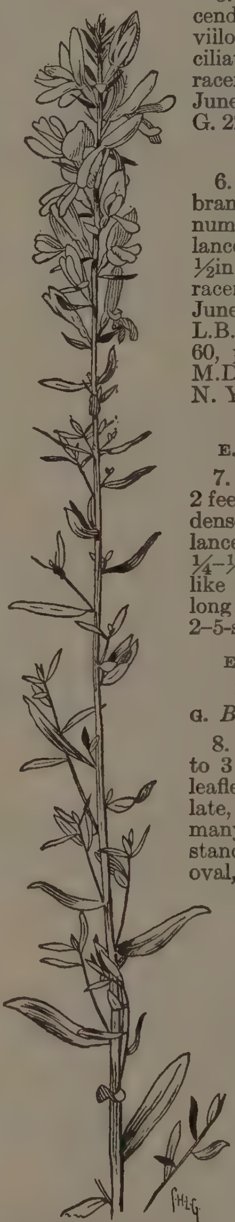
E. *Infl. racemose.*

F. *Spines stout: habit upright, to 6 ft.*

3. **fèrox,** Poir. Erect shrub, to 6 ft., with many stout spines: lvs. simple, rarely 3-foliolate, oblong to obovate, almost glabrous: fls. in numerous terminal racemes along the branches; corolla glabrous, over ½in. long, fragrant: pod linear, densely silky, many-seeded. Spring, in Calif. in autumn and winter. N. Afr. B.R. 368.

FF. *Spines slender: habit decumbent to upright, to 2 ft.*

4. **Martínii,** Verguin & Soulié (*G. Scorpius × G. Villarsii*). Decumbent shrub: branchlets tomentose: lvs. linear-lanceolate, simple, whitish pubescent on both sides, small: fls. axillary, forming terminal slender racemes; calyx pubescent; standard and keel silky. S. France; natural hybrid. Cult. in Calif.



1624. Dyer's Greenweed, Genista tinctoria. (×⅓)

5. **germánica,** Linn. Erect or ascending spiny shrub, to 2 ft., with villous branches: lvs. elliptic-oblong, ciliate: fls. small, in 1–2-in. long racemes: pod oval, villous, few-seeded. June, July. Cent. and S. Eu. R.F. G. 22:2085.

EE. *Infl. head-like.*

6. **hispánica,** Linn. Densely branched shrub, about 1 ft. high, with numerous thin spines: lvs. ovate-lanceolate, pubescent, not exceeding ½in.: fls. in 3–12-fld. short head-like racemes: pod rhombic, hirsute. May, June. Spain, S. France, N. W. Italy. L.B.C. 18:1738. R.H. 1888:36. Gn. 60, p. 395; 62, p. 95. G.M. 45:69. M.D.G. 1907:388.—Hardy in W. N. Y.

DD. *Shrubs unarmed.*

E. *Fls. in terminal heads, sessile.*

7. **umbellàta,** Poir. Erect shrub, to 2 feet, with rigid branches, forming a dense bush: lvs. simple or 3-foliolate, lanceolate or linear-lanceolate, silky, ¼–½in. long: fls. in 10–30-fld. umbel-like heads; corolla silky, over ⅓in. long: pod linear-oblong, tomentose, 2–5-seeded. April, May. Spain.

EE. *Fls. in racemes, or axillary.*

F. *Habit upright.* Nos. 8–14.

G. *Branches rigid: pod 1-seeded, silky.*

8. **ephedroìdes,** DC. Erect shrub, to 3 ft., with rigid branches, almost leafless: lvs. sessile, simple or 3-foliolate, linear, almost glabrous: fls. in many-fld. terminal racemes, small; standard much shorter than keel: pod oval, 1-seeded, silky. April, May. Sardinia, Corsica, Sicily.

GG. *Branches slender: pod 1–10-seeded.*

H. *The fls. axillary on last year's branchlets.*

9. **ætnénsis,** DC. Shrub, to 6 ft., with slender branches, nearly leafless: lvs. simple, small, linear, silky: fls. axillary, forming loose, terminal racemes, fragrant; keel shorter than the standard: pod glabrous at maturity, oblique-oval, 1–3-seeded. June, July. Sicily, Sardinia. B.M. 2674.

10. **cinèrea,** DC. Shrub, to 3 ft.: branches grooved, pubescent while young, sparsely leafy: lvs. simple, lanceolate, pubescent on both sides, ⅓–½in. long: fls. 1–3, axillary, forming terminal racemes to 8 in. long; calyx pubescent; keel pubescent outside: pod 2–5-seeded, silky. April–June. S. Eu., N. Afr. B.M. 8086. G.M. 52:511; 53:507.—This species does not seem to be in the trade at present, but it deserves attention on account of its copious, brilliant yellow fls.

HH. *The fls. in terminal racemes on the young growth.*

I. *Pod pubescent, 1–4-seeded.*

11. **virgàta,** Link (*Spártium virgàtum,* L'Her.). Shrub, to 8 ft., with slender branches: lvs. lanceolate to elliptic, silky-villous, ¼–½in. long: fls. in numerous short 3–6-fld. racemes; standard and keel silky: pod oblong, 1–3-seeded, villous. May–July. Madeira. B.M. 2265. F. 1875:169.

12. **flórida,** Linn. Erect shrub, to 5 ft., with glabrous striped branches: lvs. spatulate-oblong or lanceolate, silky beneath, ⅓–⅔ in. long: fls. in dense, many-fld. racemes; corolla glabrous: pod oblong or narrow-oblong, silky, 2–4-seeded. April–July. Spain.

II. *Pod glabrous or slightly pubescent, rarely densely so, 3–10-seeded.*

13. **polygalæfòlia,** DC. Erect shrub, to 6 ft., with somewhat silky branches: lvs. spatulate-oblong, glabrous above, sparingly silky beneath, ½–⅔in. long: fls. in many-fld. slender racemes; standard and wings glabrous, keel silky: pod oblong or narrow-oblong, almost glabrous, 3–6-seeded. May–July. Spain, Portugal.

14. **tinctòria,** Linn. (*G. sibírica,* Hort. *G. polygalæfòlia,* Hort., not DC.). DYER'S GREENWEED. Fig. 1624. Erect shrub, to 3 ft., with striped, glabrous or slightly pubescent branches: lvs. oblong-elliptic or oblong-lanceolate, almost glabrous, ciliate, ½–1 in. long: racemes many-fld., panicled at the ends of branches; corolla glabrous: pod narrow-oblong, glabrous or slightly pubescent, 6–10-seeded. June–Aug. Eu., W. Asia; naturalized in some places E. B.B. (ed. 2) 2:350. S.E.B. 3:328. R.F.G. 22:2088. Var. **plèna,** Hort. With double fls. R.H. 1899, p. 573. G.W. 16, p. 137. Var. **virgàta,** Mert. & Koch (*G. virgàta,* Willd., not Link, not Lam. *G. elàta,* Wender.). Of more vigorous growth, to 6 ft. high: pod 3–6-seeded. S.E. Eu. Var. **humílior,** Schneid. (*G. mántica,* Poll.). Dwarf and compact, more pubescent: pods silky-villous. Italy.

FF. *Habit procumbent: fls. axillary.*

15. **pilòsa,** Linn. Dwarf, procumbent or ascending: lvs. cuneate, oblong or obovate, dark green and almost glabrous above, silky beneath: fls. axillary, 1–2, often racemose toward the end of branches: pod linear, silky, 5–8-seeded. May, June. Cent. and S. Eu., W. Asia. S.E.B. 3:327. R.F.G. 22:2093.

BB. *Twigs broadly 2-winged.*

16. **sagittàlis,** Linn. (*Cýtisus sagittàlis,* Mert. & Koch). Dwarf, procumbent, with ascending or erect, mostly simple branches: lvs. ovate to oblong, villous: fls. in terminal, short racemes; corolla glabrous: pod linear-oblong, silky. May, June. Eu., W. Asia. R.F.G. 27:2081.

G. álba, Lam.=Cytisus multiflorus.—*G. Andreàna,* Puissant=Cytisus scoparius var. Andreanus.—*G. ánglica,* Linn. Spiny shrub, to 3 ft., sometimes procumbent, glabrous: lvs. oval to linear-oblong, bluish green: racemes few-fld. Cent. Eu. S.E.B. 3:326. R.F.G. 22:2086.—*G. anxántica,* Tenore (G. tinctoria var. anxantica, Fiori). Allied to G. tinctoria. Dwarf, diffuse: lvs. elliptic, obtuse, glabrous: fls. in racemes. Italy.—*G. aspalathoìdes,* Lam. Low, spiny shrub: lvs. simple or 3-foliolate: fls. 1–3, axillary, forming loose, terminal racemes: pod many-seeded. N. Afr.—*G. canariénsis,* Linn.=Cytisus canariensis.—*G. cándicans,* Linn.=Cytisus monspeliensis.—*G. dalmática,* Bartl. Allied to G. germanica. Spiny shrub with appressed or spreading silky pubescence: lvs. linear-lanceolate, simple: fls. in terminal racemes, 1–1½ in. long: pod globose-ovoid, 1-seeded. Dalmatia, Herzegovina. B.M. 8075.—*G. formòsa,* Hort.=Cytisus racemosus.—*G. glabréscens,* Briquet=Cytisus emeriflorus.—*G. hórrida,* DC. Spiny rigid shrub, to 1 ft.: lvs. opposite, usually 3-foliolate, pubescent: fls. 1–3, in terminal heads: pods rhombic-lanceolate, pubescent. S. France, Spain. G.C. III. 53:140.—*G. júncea,* Lam.=Spartium junceum.—*G. lusitánica,* Linn. Spiny shrub, 1–3 ft.: lvs. 3-foliolate; lfts. linear-lanceolate, silky, very small: fls. in peduncled heads. Spain, Portugal.—*G. nyssàna,* Petrovich. Shrub, to 3 ft., silky-villous: lvs. 3-foliolate: fls. in terminal leafy racemes to 8 in. long: pod rhombic, villous, 2-seeded. Servia, Albania. I.T. 5:197.—*G. ovàta,* Waldst. & Kit. Allied to G. tinctoria. To 1 ft., with ascending or erect branches: lvs. ovate to lanceolate, villous: pod villous. S. E. Eu. L.B.C. 5:482.—*G. prostràta,* Lam.=Cytisus decumbens.—*G. racemòsa,* Hort.=Cytisus racemosus.—*G. radiàta,* Scop. Erect shrub, with opposite rigid branches: lvs. simple or 3-foliolate: fls. in 3–6-fld. heads: pod oval, silky. S. E. Eu. B.M. 2260.—*G. Retàma,* Nichols.=G. monosperma.—*G. scariòsa,* Viv.=G. triangularis.—*G. scopària,* Lam.=Cytisus scoparius.—*G. triangulàris,* Willd. Dwarf, with ascending or procumbent triangular branches, glabrous: lvs. obovate to lanceolate, with transparent margin: fls. in short racemes. Italy. S. E. Eu. L.B.C. 12:1135 (as G. scariosa).

ALFRED REHDER.

GENTIÀNA (after Gentius, King of Illyria, who is said to have discovered the tonic value of these plants). *Gentianàceæ.* Choice herbs, mostly blue-flowered, grown in the open, many of them in alpine gardening.

Chiefly perennial herbs, only rarely biennial or annual, often dwarf, diffuse or frequently tufted, sometimes erect and slender or even tall and stout: lvs. opposite, rarely verticillate, mostly sessile: fls. blue, violet, purple, rarely dull yellow or white; floral parts typically 5, rarely 4–7: fr. a caps.—There are about 300 species, widely scattered in temperate and mountainous regions. Many botanists now consider the genus in a highly restricted sense, taking up various names for gentians, such as Amarella, Dasystephana, and so on, but they are here all considered as of the genus Gentiana.

Gentians are amongst the most desirable of alpine plants, and of blue flowers in general, but they are usually considered difficult to establish. The genus is the largest in the family, and from the horticultural standpoint, the most important.

The blue gentian, celebrated by tourists in the Alps, is mostly the stemless *G. acaulis.* This was brought to English gardens so long ago that all record of its introduction is lost. It is by far the most popular kind in cultivation. This species is by some split into five distinct forms, of which *G. angustifolia,* Vill. (not Michx.), is nearest to the Gentianella of English gardens. It has been so much modified in cultivation that it now has stems 4 to 6 inches high and the rootstock is so stoloniferous that the plant has to be cut back every year when used for edgings in English gardens. In France it is easily grown in a compost of one-half humus or leaf-soil and one-half good vegetable mold, to which may be added a little sand. Correvon writes: "It can be multiplied by means of offsets, but it is infinitely better to raise it from seed, and, in doing this, it should not be forgotten that the seeds of this group of gentians are very tedious, and, more especially, very capricious in germinating. I have sown seeds of *G. acaulis,* some of which did not germinate for twelve months, while others (which I must say were more recently gathered) germinated in a few weeks. The seedlings should be potted as soon as possible and while they are very young. They will begin to flower in about three years from the time of sowing, rarely sooner." Except *G. Andrewsii, G. Saponaria* and *G. puberula,* and perhaps a few others, gentians do not thrive so well in America as in England. Our seasons are too hot and dry. Whenever possible, choose a damp atmosphere.

It is rash to generalize on gentian-culture, because some plants are tall, others dwarf, some found on mountains, others in lowlands, some in moist soil, others in dry lands, while some like limestone and others cannot endure it. The annual kinds are of interest only to the expert. Alpine plants in general are singular in requiring an extremely large water-supply, combined with extremely good drainage. Another difficult problem is to keep the plants as cool as they are on the mountains without shading them more than nature does. Gentian seeds are small, and in germination slow and uncertain. They should be sown as soon as gathered, for the thorough drying out of small seeds is, as a rule, soon fatal. Gentians are difficult to establish, and dislike division of the root, but are well worth patient years of trial, for they are very permanent when once established. Nature-like alpine gardens are one of the latest and most refined departments of gardening, and gentians are one of the most inviting groups of plants to the skilled amateur. Consult *Alpine Plants.*

There are several fringed gentians, but ours (*G. crinita,* Fig. 1625) is perhaps the most beautiful of gentians, and one of the choicest and most delicate of American wild flowers. It has been proposed as our national flower, and, while sought after less than the trailing arbutus, it is in even greater danger of extermination in certain states because it is a biennial, and because it has never been successfully cultivated. Seeds of *G. crinita* have long been advertised, but they are difficult to germinate and the plant is not seen in American gardens. The fringed gentian is, however, firmly rooted in American literature, and from the time of Bryant's ode many tributes in verse have been paid to its unique beauty. The daily unfolding of its square-ridged and twisted buds has been watched in thousands of homes. By the artists its blue is often considered the nearest approach to the color of the sky, but it must be confessed that a shade of purple often appears in the older flowers.

1625. Gentiana crinita. (×⅜)

Correvon makes four cultural groups of gentians:

1. *Tall gentians for general culture:* species whose roots are more or less stout, which are of relatively easy culture, and therefore suitable for borders, rockwork and landscape gardening. Typical plant, *G. lutea;* others are *G. affinis, G. alba, G. Andrewsii, G. asclepiadea, G. Bigelovii, G. Burseri, G. Cruciata, G. decumbens, G. Fetisowii, G. gelida, G. Kesselringii, G. macrophylla, G. Olivieri, G. Pneumonanthe, G. Porphyrio, G. Saponaria, G. sceptrum, G. septemfida* and *G. Walujewi.*
2. *Low-growing gentians:* species whose roots being less stout are adapted to rockwork, and for the open ground only when a special compost is provided. Includes *G. acaulis* and the species into which it is sometimes divided.
3. *Tufted gentians:* species with sessile flowers growing little above the level of the ground, and suited to the same positions as Group II. Typical plant, *G. verna:* others are *G. bavarica, G. imbricata, G. oregana, G. ornata, G. pyrenaica,* and *G. pumila.*
4. *Rare gentians:* species which cannot be grown without some special knowledge and practical experience. Typical plant, *G. purpurea;* others are *G. ciliata, G. Froelichii, G. punctata,* and presumably all the rest.

The two most popular gentians in American cultivation seem to be *G. acaulis* and *G. Andrewsii.* These are perhaps, followed by *G. Cruciata, G. puberula* and *G. Saponaria.* The plant which King Gentius knew is probably *G. lutea,* the root of which furnishes the gentian of drugstores. From the same sources comes the liqueur or cordial called "gentiane."

In the index, those marked with an asterisk (*) appear in American trade catalogues; the others are cultivated abroad. (See also Suppl. list, p. 1328). The plants are perennials and mountain-loving, unless otherwise stated.

KEY TO THE SPECIES.

A. *Calyx spathe-like, split in two.*
B. *Color of fls. yellowish.*
C. *Form of corolla wheel-shaped*..... 1. **lutea**
CC. *Form of corolla club-shaped, at least in bud*.................. 2. **Burseri**
BB. *Color of fls. blue or purple, at least above.*
C. *Corolla plaited*................. 3. **decumbens**
CC. *Corolla not plaited.*
D. *Anthers grown together*......... 4. **purpurea**
DD. *Anthers free*.................. 5. **rubra**
AA. *Calyx with a tubular portion, and usually 5 lobes.*
B. *Color of fls. yellowish, or greenish white.*
C. *Style distinct: caps. not stalked*.... 6. **punctata**
CC. *Style none or very short: caps. stalked.*
D. *Height 2 ft*.................... 7. **alba**
DD. *Height 9–12 in*................ 8. **villosa**
DDD. *Height 6 in. or less.*
E. *Lobes of calyx longer than the calyx-tube*................ 9. **frigida**
EE. *Lobes of calyx shorter than the calyx-tube.*
F. *Lvs. lanceolate-linear*........10. **algida**
FF. *Lvs. ovate-lanceolate*.........11. **gelida**
BB. *Color of fls. blue or purple.*
C. *Corolla not plaited.*
D. *Glands found at the base of the filaments.*
E. *Calyx 4-cut*.................12. **campestris**
EE. *Calyx 5-cut*.................13. **Moorcroftiana**
DD. *Glands not found at the base of the filaments.*
E. *Fringed gentians: calyx 4-cut.*
F. *Caps. raised on a distinct stalk.*
G. *Apex of lobes fringed, the sides less so*.............14. **crinita**
GG. *Apex of lobes not fringed, base fringed*.............15. **ciliata**
FF. *Caps. on a very short stalk*...16. **serrata**
EE. *Not fringed: calyx 5-cut; corolla-lobes tipped with a sharp point*....................17. **quinquefolia**
CC. *Corolla plaited.*
D. *Stigmas 2, always distinct.*
E. *Caps. finally raised on a distinct stalk.*
F. *Anthers permanently grown together.*
G. *Calyx as long as the corolla.*18. **Froelichii**
GG. *Calyx one-half or one-third as long as the corolla.*
H. *Seeds not at all winged*...19. **asclepiadea**
HH. *Seeds slightly winged.*
I. *Fls. open*..............20. **Pneumonanthe**
II. *Fls. closed, blue*.........21. **Saponaria**

HHH. *Seeds strongly winged.*
I. *Fls. closed, purple*.......22. **Andrewsii**
II. *Fls. open*..............23. **linearis**
FF. *Anthers free, at least finally.*
G. *Number of corolla-lobes 10*.24. **pyrenaica**
GG. *Number of corolla-lobes 5 (rarely 4).*
H. *Calyx 4-lobed*...........25. **prostrata**
HH. *Calyx 5-lobed.*
I. *Lvs. distinctly rough above (hispid-scabrous)*......26. **scabra**
II. *Lvs. distinctly rough at the margins (scabrous).*
J. *Lobes of calyx shorter than the calyx-tube*...27. **Fortunei**
JJ. *Lobes of calyx as long as the calyx-tube.*
K. *Corolla-lobes ovate, acute, a little longer than the much-cut appendages*........28. **septemfida**
KK. *Corolla-lobes oblong-lanceolate, obtuse, thrice as long as the much-cut appendages*............29. **affinis**
III. *Lvs. not distinctly rough above or at margins.*
J. *Seeds not at all winged.*
K. *Form of corolla-lobes linear-oblong*.......30. **Olivieri**
KK. *Form of corolla-lobes ovate, often broadly so.*
L. *Fls. solitary.*
M. *Peduncled*.......31. **Porphyrio**
MM. *Not peduncled*....32. **ornata**
LL. *Fls. in clusters of 3–5 or more.*
M. *Lvs. lanceolate-linear*.........33. **triflora**
MM. *Lvs. ovate to oblong-lanceolate.*
N. *Height 2–4 ft*.....34. **sceptrum**
NN. *Height 9–12 in.*
O. *Calyx-lobes ovate, about as long as the calyx-tube*....35. **calycosa**
OO. *Calyx-lobes linear, moderately or much shorter than the calyx-tube*.36. **Parryi**
JJ. *Seeds winged (at the base in G. Kurroo, in G. Bigelovii wings narrow, thickish).*
K. *Height 2–8 in.: fls. spotted.*
L. *Pedicel ½in. long or more*............37. **Kurroo**
LL. *Pedicel very short, practically absent*..38. **Newberryi**
KK. *Height 1–2 ft.*
L. *Fls. in a dense spike*.39. **Bigelovii**
LL. *Fls. 1 to few or several.*
M. *Appendages conspicuous, sometimes nearly as long as the corolla-lobes*..........40. **oregana**
MM. *Appendages only half as long as the corolla-lobes*..41. **puberula**
EE. *Caps. sessile.*
F. *Anthers grown together; style distinct: seeds winged.*
G. *Calyx 5-cut, the lobes longer than the calyx-tube*.......42. **pannonica**
GG. *Calyx entire, truncate, indistinctly 5-lobed*..........43. **Gaudiniana**
FF. *Anthers free; style usually not distinct: seeds not winged.*
G. *Lvs. 6-12 in. long: calyx 5–6-lobed*..................44. **macrophylla**
GG. *Lvs. much shorter: calyx 4-lobed*...................45. **Cruciata**
DD. *Stigmas contiguous, rather funnel-shaped, the margin crenate-fimbriate.*
E. *Anthers free; style distinct.*
F. *Calyx pellucid, veiny*........46. **carpatica**
FF. *Calyx leafy.*
G. *Seeds winged*.............47. **imbricata**
GG. *Seeds not winged.*
H. *Lvs. ovate*..............48. **verna**
HH. *Lvs. obovate*............49. **bavarica**
HHH. *Lvs. linear*.............50. **pumila**
EE. *Anthers connate; style short.*
F. *Fls. spotted.*
G. *Color deep blue*..........51. **acaulis**
GG. *Color sky-blue*...........52. **angustifolia**
GGG. *Color violet-blue*..........53. **Kochiana**
FF. *Fls. not spotted.*
G. *Corolla broadly bell-shaped.*
H. *Size of fls. large*.........54. **Clusii**
HH. *Size of fls. small*........55. **alpina**
GG. *Corolla almost cylindrical*..56. **dinarica**

1. **lùtea,** Linn. Fls. in dense, umbel-like cymes; corolla 5–6-parted; lobes oblong-linear, acuminate; anthers free; style none. July–Sept. Eu., Asia Minor. Gn. 64, p. 59. G.W. 3, p. 290.—Prop. only by seed. Sow seed in Nov. in coldframe. Seedlings appear the following March and April. In May and June prick them out under a coldframe, and in Aug. transfer young plants to pots, where they should be kept until needed for permanent outdoor use. Be very careful never to break the roots. Sometimes cult. abroad for medicine.

2. **Búrseri,** Lapeyr. A low perennial, less than 1 ft., with a simple st.: lvs. elliptic-ovate, 7-nerved: corolla mostly 6-cut; the tube much longer than the limb; lobes ovate-oblong, acute; anthers connate; style distinct. June, July. Pyrenees.—Cult. like preceding.

3. **decúmbens,** Linn. f. (*G. adscéndens,* Pall.). A stout, erect herb with fl.-sts. 2–10 in. tall: lvs. mostly radical, oblong or elliptic, margins scabrous: fls. blue; calyx-tube ⅓in. long, often split nearly to the base; corolla narrowly obconical, toothed between the lobes; lobes 5, ovate; anthers connate, finally free. Himalayas, Tibet. June–Aug. B.M. 705, 723.—Cult. like *G. lutea.*

4. **purpùrea,** Linn. Lvs. ovate-oblong, 5-nerved: fls. purple above; corolla-tube yellowish, club-shaped; lobes mostly 6, obovate-subrotund, one-third the length of the tube. Aug., Sept. Eu. L.B.C. 6:583 shows a rich, dull purple, with no trace of blue.—Compost of sphagnum and heath soil. Be careful not to break the roots.

5. **rùbra,** Clairv. (*G. Thómasii,* Gillaboz). One of 5 or more natural hybrids between *G. lutea* and some species of the section Cœlanthe, which includes *G. punctata, G. purpurea, G. Pannonica,* and *G. Burseri:* fls. purplish outside. Swiss Alps.

6. **punctàta,** Linn. Lvs. 5-nerved: calyx 5–7-cut; corolla-tube bell-shaped; lobes ovate, muticous, one-third the length of the tube; anthers finally free. Cent. Eu.—The spots are not arranged in any definite order. This belongs to the section Cœlanthe, in which the seed has a wing of the same color, while the next 5 species belong to the section Pneumonanthe, in which there is no wing, or it is of a different color. Cult. like *G. Froelichii.*

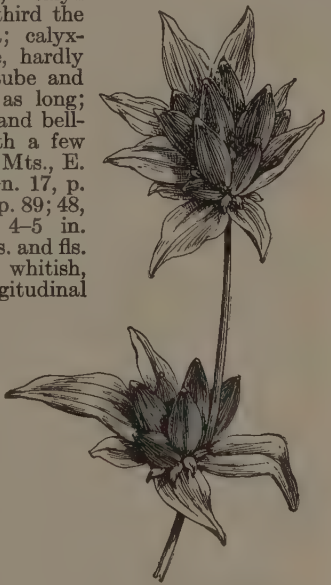
7. **álba,** Muhl. St. stout: lvs. acuminate, with a clasping base: fls. in a terminal head, with single or clustered ones in the upper axils; dull white, commonly tinged yellowish or greenish; corolla resembling *G. Saponaria,* but more bell-shaped and open; lobes ovate, short, little if at all spreading. Low grounds and mountain meadows, N. Amer. B.M. 1551 (as *G. ochroleuca*).—This species now takes the name **G. flávida,** Gray.

8. **villòsa,** Linn. (*G. ochroleùca,* Froel.). St. smooth scending, simple or nearly so, slender, 6–18 in. tall: lvs. ovate-lanceolate and obovate: fls. in crowded terminal, nearly sessile, leafy clusters, or sometimes axillary; corolla yellowish white or greenish, club-shaped, connivent at the apex. E. N. Amer. Not B.M. 1551. Var. **intermèdia,** Griseb. (*G. intermèdia,* Sims, not L.B.C. 3:218), may be a hybrid between this and *G. Andrewsii.* It resembles *G. ochroleuca* in having calyx-lobes of unequal lengths, but as long as or longer than the calyx-tube, and free anthers: it resembles *G. Andrewsii* in the tinge of purplish blue. B.M. 2303. Var. **incarnàta,** Griseb. (*G. incarnàta,* Sims), B.M. 1856, from Carolina is not cult. These forms are not considered worthy of varietal rank in Gray's Syn. Fl.

9. **frígida,** Hænke. Lvs. spatulate-linear, obtuse: fls. 1 or 2 at the top, sometimes a few in the upper axils; calyx not laterally cut, and half as long as the corolla or more; calyx-teeth lanceolate, a little longer than the calyx-tube; corolla club-shaped, plaits not cut. Carpathian Mts.; also N. Amer.—This is the true type of *G. frigida,* which is not in cult., but is inserted to make clear the differences between *G. algida* of Pallas and of Steven.

10. **álgida,** Pall., not Stev. (*G. frígida* var. *álgida,* Griseb.). Lvs. lanceolate-linear: fls. 2–5 at the top and distinctly pedicelled; calyx laterally cut and one-third the length of the corolla; calyx-teeth linear-lanceolate, hardly as long as the calyx-tube and sometimes only half as long; corolla between club- and bell-shaped; plaits cut with a few crenate teeth. Altai Mts., E. Siberia, N. Amer. Gn. 17, p. 343, same as Gn. 27, p. 89; 48, p. 146.—This grows 4–5 in. high, has numerous sts. and fls. nearly 2½ in. long, whitish, with blue spots in longitudinal lines.

11. **gélida,** Bieb. (*G. álgida,* Stev., not Pall.). Lvs. ovate-lanceolate, 3-nerved: fls. few and terminal, or many in the upper axils, peduncled; calyx-teeth linear-oblong, acute, nearly as long as the calyx-tube or shorter than it; corolla rather bell-shaped, yellowish white, its lobes broadly ovate, twice as long as the calyx and twice as long as the lacerated plaits. June, July. Caucasus. Not P.M. 7:5, which is *G. septemfida* var. *cordifolia.*—"Light, deep, cool soil and full sunlight."—Correvon.



1626. Gentiana Andrewsii.

12. **campéstris,** Linn. A low slender annual with erect st. 2–6 in. tall: lvs. sessile, ovate-lanceolate, 3–5-nerved: fls. dark purplish blue, short-pedicelled, but in various kinds of clusters; calyx 4-cut; corolla nearly bowl-shaped, crowned; anthers free; style none. Eu.

13. **Moorcroftiàna,** Wall. A stiff annual 8–16 in. high: fls. pale blue in nearly terminal cymes which are racemosely clustered; calyx 5-cut; corolla funnel-shaped, about 1½ in. wide. Himalayas. B.M. 6727, where fls. are shown as pale purple.

14. **crinìta,** Froel. Fig. 1625. FRINGED GENTIAN. Biennial or often annual: erect, branched, 1–2 ft. high: lvs. lanceolate or ovate-lanceolate, acutish, from a rounded or subcordate partly clasping base: corolla-lobes wedge-obovate: seeds roughened by scales or needle-like projections. Moist woods and meadows. N. Amer. B.M. 2031. Mn. 4:161. B.B. 2:613.—The ribs of the calyx (made by the decurrent lobes) are one of the minor beauties of this plant, and are probably more pronounced than in the other fringed gentians here described. Almost impossible to grow in cult.

15. **ciliàta,** Linn. Perennial: st. flexuose, scarcely branched: lvs. linear, obtuse: corolla-lobes obovate-oblong: seeds smooth. Dry limestone soils. Eu. Not B.M. 639, which is *G. serrata.*—Hardly 3 per cent of Correvon's seedlings have flowered. He recommends a heavy, compact soil which is almost clayey, and full sunlight.

16. **serràta,** Gunner (*G. barbàta,* Froel. *G. detónsa,* Griseb. *G. detónsa* var. *barbàta,* Griseb.). Annual: st. erect, branching, 3–18 in. high: lvs. linear or lance-linear: corolla-lobes oblong or spatulate-obovate, fringed around the apex and sides or sometimes either part nearly bare. Wet lands, Ural and Altai Mts., Caucasus, N. Amer. B.B. 2:614. B.M. 639 (erroneously as *G. ciliata*).—No plants appear to be advertised as *G. serrata. G. barbata* is a trade name abroad.

17. **quinquefòlia,** Linn. (*G. quinqueflòra,* Hill, Lam. and others). Annual: height 1–2 ft., the larger plants branched: lvs. 3–7-nerved: infl. thyrsoid-paniculate; clusters 3–5-fld.; fls. bright blue; calyx one-fifth or one-fourth as long as the narrowly funnel-shaped corolla. N. Amer. Probably the form in cult. is var. **occidentàlis,** Gray. Height 2–3 ft., paniculately much branched: infl. more open; calyx half the length of the broader corolla. B.B. 2:615. B.M. 3496.—Very pretty.

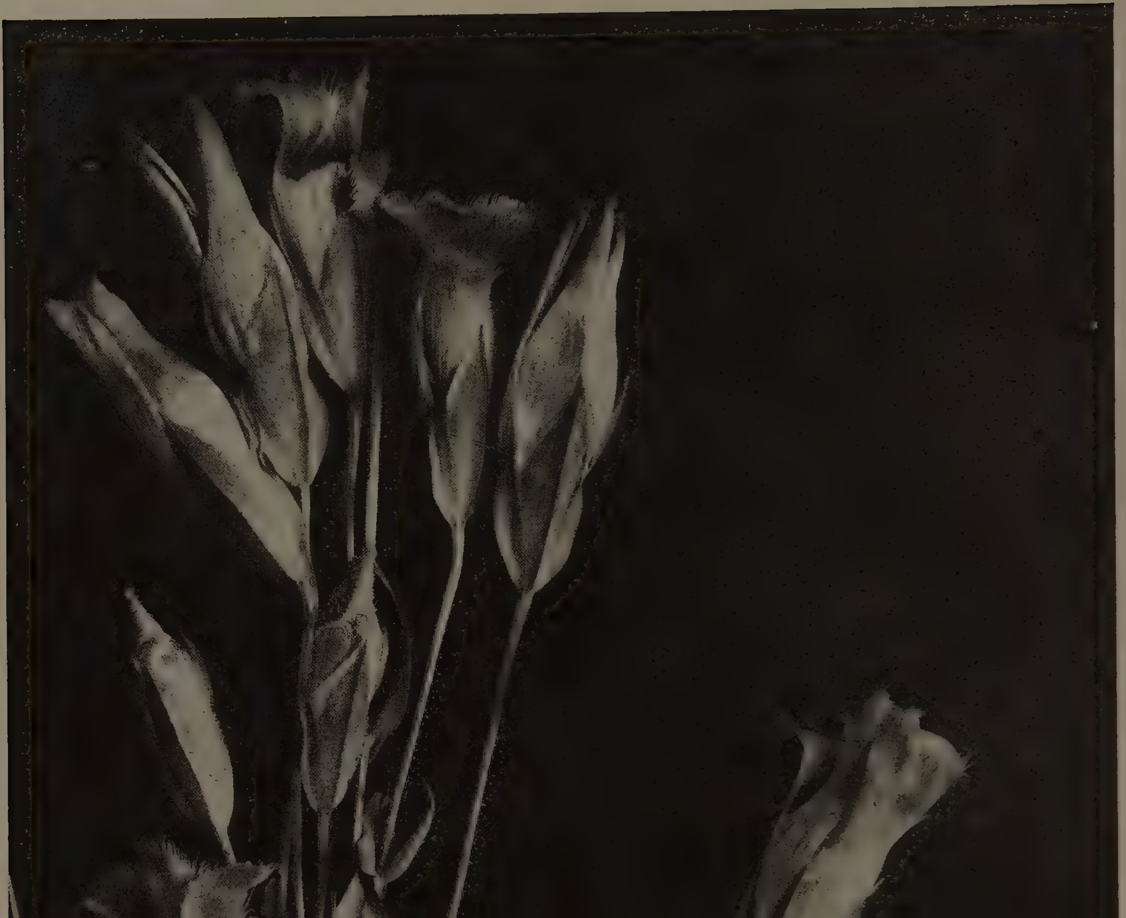
18. **Froèlichii,** Jan. Sts. short, almost tufted: fls. blue, solitary, peduncled, nearly as long as the st.; corolla not spotted. Very rare in Alps, limestone rocks.—Easily grown on rockwork in compost of equal parts of sphagnum, heath soil and vegetable-mold. Half-exposure to sunlight.

19. **asclepiádea,** Linn. St. strict, about 1–1½ ft. tall: lvs. sessile, ovate-lanceolate: calyx-teeth very short: fls. in spike-like racemes, dark blue, very showy; corolla club-shaped; calyx one-third as long as the corolla: seeds not winged. July–Sept. S. Eu., Caucasus. B.M. 1078. Gn. 48, p. 143, and 54, p. 39. G.M. 47:544. Gt. 54, p. 345. G. 3:59; 8:481; 13:403; 21:233. Var. **álba,** a white-fld. form is excellent but perhaps not known outside of English trade. Shade or half-shade, and moist, deep soil rich in humus.

20. **Pneumonánthe,** Linn. St. erect: fls. dark blue in a cyme-like raceme (the top fls. opening first); corolla club-shaped; lobes ovate, acute, mucronate, much longer than the appendages. Aug.–Oct. Mountain marshes, Eu., N. Asia. Var. **guttàta,** Sims, is dotted white. B.M. 1101.—"Requires a cool, deep, spongy soil, rich in humus. Dislikes lime, and prefers sandy soil. Does remarkably well when planted on margins of ponds or brooks. Prop. by seed or division."—Correvon.

21. **Saponària,** Linn. (*G. Catésbæi,* Walt., not Andr.). BARREL OR SOAPWORT GENTIAN. St. ascending: fls. light blue, club-shaped; calyx-lobes linear or oblong, mostly as long as the calyx-tube; corolla-lobes short, broad, roundish, erect, little, and often not at all longer than the 2-cleft and many-toothed intervening appendages. N. Amer. B.M. 1039. (Hooker is probably wrong in referring this picture to *G. Andrewsii,* although the calyx-lobes in the plate are not narrow enough.)—Cult. like preceding.

22. **Ándrewsii,** Griseb. (*G. Catésbæi,* Andr., not Walt.). CLOSED, BLIND OR BOTTLE GENTIAN. Fig. 1626. St. ascending: fls. purplish blue; calyx-lobes lanceolate to ovate, usually spreading or recurved, shorter than the calyx-tube; corolla-lobes entirely obliterated, the teeth at the top being supposed to be the remains of the



XLVII. Gentiana crinita.

appendages often found between the corolla-lobes in other species. July, Aug. Moist places. E. N. Amer. B.M. 6421. B.B. 2:616. Gn. 27:86. G.W. 4, p. 549. F.W. 1879:33. L.B.C. 9:815 (erroneously as *G. Saponaria*).—A white-fld. form is cult. but very rare. For cult., see *G. Pneumonanthe*.

23. **lineàris,** Froel. (*G. pseùdo-Pneumonánthe*, Schult.). St. strict, 1–2 ft. high: fls. blue, 1–5 in the terminal cluster; corolla narrowly funnel-shaped; lobes erect, roundish ovate, obtuse, a little longer than the triangular, acute, entire or 1–2-toothed appendages. Bogs, N. Amer. B.B. 2:617.

24. **pyrenàica,** Linn. St. tufted, about as long as the fl., often forming mats: lvs. with a cartilaginous, scabrous margin: fls. solitary, dark blue; corolla funnel- or nearly bowl-shaped, as long as or exceeding the corolla which is about 1 in. long. May, June. Eu., Asia Minor. B.M. 5742.—Very distinct and dainty. Cult. like *G. verna*.

25. **prostràta,** Hænke (*Chondrophýlla americàna*, Nelson). Annual, dwarf: lvs. white-margined: fls. azure-blue, solitary and terminal, the parts in 4's; corolla salver-form, in fruit inclosing the long-stalked caps. W. N. Amer. Alpine.

26. **scàbra,** Bunge. St. erect, leafy, rough-hairy above: basal lvs. almost perfoliate, ovate, acute, faintly 3-nerved, the margins rough toothed: fls. dark blue, clustered; corolla bell-shaped. E. Asia. *G. Fortunei* is considered a variety by recent authorities. (G.C. III. 47:136). Var. **Buérgeri** (*G. Buérgeri*, Miq.) is advertised by Yokohama Nursery Co. It differs in having a narrower corolla with shorter and more triangular lobes. Probably not in Amer. except in botanic gardens.

27. **Fórtunei,** Hook. Lvs. rather distant, 3-nerved: terminal fls. rather clustered; corolla-lobes blue, spotted white; outside of tube green; plaits blue, terminated by 3-toothed appendages, much shorter than the corolla-lobes. China. B.M. 4776. F.S. 9:947. I.H. 1:36.—Now thought to be a variety of *G. scabra*, but not so considered by Miquel.

28. **septémfida,** Pall. Lvs. lanceolate ("ovate," according to Grisebach), 3–5-nerved: fls. dark blue, in head-like cymes; calyx-lobes linear; corolla club-shaped. July–Oct. N. Asia, Orient. B.M. 1229 and 1410 (both purple outside and dotted brown within; the lobes of the latter spotted white). G. 34:773. L.B.C. 1:89. Gn. 54, p. 37. P.M. 8:51. Not F.S. 8:765. *G. Freyniàna*, Hort., is said to differ from the type in having larger fls. which are less prominently fringed between the segms. of the corolla. G.C. III. 46:202. Gn. 75, p. 421; 77, p. 168. Var. **cordifòlia,** Boiss. (*G. cordifòlia*, C. Koch), has heart-shaped lvs.: corolla-tube greenish white outside, unspotted within; lobes narrower, unspotted. B.M. 6497. P.M. 7:5 (erroneously as *G. gelida*).—The name septemfida is misleading, as 7-lobed corollas are very rare. Cult. like *G. lutea*.

29. **affìnis,** Griseb. Sts. clustered, 3–9 in. high: lower lvs. obovate-oblong; upper lvs. lanceolate, acutish: fls. dark blue, in thyrsoid-racemose clusters, a few or sometimes solitary; calyx-lobes oblong-linear and sharp-pointed; corolla narrowly obconical, open, the lobes spreading. N. W. Amer. Gn. 46, p. 77 and 48, p. 139. B.B. 2:615 (where corolla-lobes are pictured erect, but said to be spreading).—Cult. like *G. Pneumonanthe*.

30. **Olivièri,** Griseb. (*G. dahùrica*, Fisch., which is probably the oldest name). Fls. dark blue, in umbel-like cymes; corolla narrowly obconical; plaits triangular, nearly entire. June–Aug. Mountain pastures, Asia.—By recent authority referred to *G. decumbens*, but differing from that species only in having equal calyx-lobes. Cult. like *G. lutea*.—Useful in the rockery, but will not grow well in the hot dry summer of E. U. S.

31. **Porphýrio,** J. F. Gmel. (*G. angustifòlia*, Michx., not Vill.). Lvs. narrowly linear: fls. blue, somewhat brown-dotted (also a snow-white variety with a greenish hue outside); corolla funnel-shaped; anthers connivent but never connected. July, Aug. Moist pine-barrens, N. Amer. B.B. 2:618.—Cult. like *G. Pneumonanthe*.

32. **ornàta,** Wall. Branches many from the same root: lvs. broadly linear: fls. solitary, blue, streaked; calyx-lobes spreading; corolla ventricose, about 1–1¾ in. long; lobes very short, spreading. Himalayas. B.M. 6514 and 8140. G.C. II. 20:396; III. 46:179. Gn. 59, p. 249.—A form that differs from the type in being more robust, with larger fls. and broader corolla-lobes which are "intense blue," is offered as *G. Veitchiòrum*, Hemsl. It is a native of W. China, "where it covers large areas," according to E. H. Wilson (Naturalist in Western China, 1:139), its discoverer. Intro. into England in 1904. Alpine. Gn. 73, p. 479. G.C. III. 46:178.

33. **triflòra,** Pall. St. erect: lvs. oblong-linear, blunt: fls. solitary, dark blue, the calyx 5-toothed, acute, and elongate; corolla club-shaped or bell-shaped, the anthers free. E. Siberia.—Probably not now in cult. in Amer. outside of botanic gardens.

34. **scéptrum,** Griseb. An erect, leafy perennial, from 2–4 ft. high: lvs. oblong-lanceolate: fls. dark blue; corolla bell-shaped, about 1 in. long: seeds winged on one side according to Grisebach, but Gray says not winged. Aug., Sept. N. W. Amer.—Cult. like *G. lutea*, except that it requires half shade and a rather peaty soil.

35. **calycòsa,** Griseb. About 1 ft. high: lvs. ovate, about ¾in. long, the 2 upper commonly involucrate around the fl.: fls. dark blue, commonly solitary, according to Gray; corolla oblong-funnel-shaped; appendages triangular-awl-shaped, laciniate or 2-cleft at the tip. N. W. Amer. G.M. 47:541.

36. **Párryi,** Engelm. Sts. many, from a rather woody root, about 9 in. tall: lvs. somewhat glaucous, ovate to oblong-lanceolate, the upper pairs involucrate around the 1–5 purple-blue fls.: appendages narrow, deeply 2-cleft. N. W. Amer.

37. **Kurroò,** Royle. St. tufted, as high as 7 in.: lower lvs. lanceolate, upper linear: fls. blue, spotted white inside, 1–3 on a st.; corolla bell-shaped. Himalayas. Gn. 17:264. B.M. 6470. Var. **brévidens** has shorter calyx-lobes. J.H. III. 30:3.

38. **Néwberryi,** Gray. St. 2–4 in. high: lower lvs. obovate or spatulate: fls. pale blue, white inside, greenish dotted; calyx-lobes oblong or lanceolate, nearly as long as the tube; corolla broadly funnel-shaped, its lobes ovate and sharp-pointed. N.W. Amer. Alpine.

39. **Bígelovii,** Gray. St. 6–16 in. high, equally leafy to the summit: fls. purple; corolla more narrowly funnelform and smaller than in *G. affinis*. July, Aug. New Mex., Colo. B.M. 6874.—"Soon forms large clumps, often with 40–50 sts. from a single plant, each bearing 10–20 bright blue fls."—D. M. Andrews.

40. **oregàna,** Engelm. Height 1–2 ft.: lvs. ovate or ovate-oblong, 1–1½ in. long: fls. blue, a few at the summit or several and loosely racemose; corolla broadly funnel-shaped, over 1 in. long; lobes short, roundish. July, Aug. N. W. Amer.

41. **pubérula,** Michx. Perennial, usually solitary-stemmed herb from 8–18 in. tall: lvs. oblong-lanceolate to lanceolate-linear: fls. blue, sessile or nearly so in the upper axils; corolla open-funnel-shaped, 1½–2 in. long; lobes ovate. E. N. Amer. B.B. 2:615.

42. **pannónica,** Scop. A tall stout perennial: lower lvs. broadly elliptical, 5-nerved, margin scabrous; upper ones ovate-lanceolate, also 5-nerved: fls. purple above; calyx 5–7-cut; corolla leathery, distinctly spotted; anthers connate at first, finally free. Eu.

43. **Gaudiniàna,** Thom. Natural hybrid with the habit of *G. purpurea,* but the membranous corolla of *G. punctata:* fls. rosy violet. Eu., but not widely cult.

44. **macrophýlla,** Pall. Perennial, with erect or ascending st.: lvs. lanceolate, distant, very spreading, 3-nerved, the upper often connate-perfoliate; internodes unequal: fls. dark blue. July, Aug. B.M. 1414, not L.B.C. 3:218. N. Eu. and Asia.—Cult. like *G. lutea.*

45. **Cruciàta,** Linn. (*Cruciàta verticillàta,* Gilib.). An erect and leafy perennial: lvs. ovate-lanceolate, crowded, erect-spreading, the upper connate-perfoliate; internodes equal: fls. axillary, in sparse clusters, dark blue. June–Aug. Eu., N. Asia.—Cult. like *G. lutea.* Prefers limestone and full sunlight.

46. **carpática,** Kit. (Probably *G. nivàlis,* Linn.). A slender perennial with small obovate lvs.: fls. solitary, axillary or terminal, dark blue (as are the next 4 species); corolla funnel-shaped, scarcely exceeding ¾in. long. Carpathian Mts.—Little known.

47. **imbricàta,** Froel. Lvs. acute, margins scabrous, (the next 3 species with smooth margins): corolla-lobes subrotund. June, July. Limestone rocks, Alps.—In this and the next 3 species, the corolla-lobes are usually crenate, half the length of the tube, and 6 times the length of the plaits. "Eastern and granitic Alps."—Correvon. Cult. like *G. bavarica.*

48. **vérna,** Linn. Fig. 1627. Tufted: st. angled: lvs. ovate or ovate-lanceolate: fls. solitary; calyx membranaceous; corolla nearly bowl-shaped; lobes ovate, obtuse. Apr.–June. Eu., Caucasus. B.M. 491. L.B.C. 1:62. R.H. 1859, p. 250. Gn. 48, p. 139; 75, p. 284. G.C. II. 24:373. J.H. III. 52:58. G.W. 23:431. Var. **alàta,** Griseb. (*G. angulòsa,* Bieb.), is taller and has the nerves of the ventricose calyx produced into wings.—Rockwork, in a compost of heath-soil, finely crushed granite, and vegetable-mold, with full sunlight. A supposed hybrid between this and the following has been described as *G. Favràtii,* Hort. The plant is practically unknown in Amer.

49. **bavárica,** Linn. Calyx-lobes lanceolate; corolla funnel- or nearly bowl-shaped; lobes obovate, obtuse; ovary sessile: seeds not winged. May–Aug. Cent. Eu. F.S. 7:651. L.B.C. 13:1256. J.H. III. 35:585. Gn. 15:278 (poor).—The pictures cited all show a salver-shaped corolla. "Requires a soil that is peaty, or at the very least porous and cool, well drained, and capable of retaining an abundant supply of moisture, although it may be fully exposed to the sun. In the alpine garden here we grow them in pure sphagnum moss on a wall facing due south, but the plants which we raise for sale are grown in pots in a compost of sphagnum, heath-soil and sand. Finest of Group III."—Correvon.

1627. Gentiana verna. (×2/5)

50. **pùmila,** Jacq. A tiny almost moss-like gentian with a 3–4-angled st.: lvs. clustered, scarcely more than ½in. long: fls. solitary terminal; calyx-lobes linear; corolla deep blue, the lobes ovate, acute. June, July. Tyrolese and Carinthian Alps.

51. **acaùlis,** Linn. (*G. excìsa,* Presl.). GENTIANELLA. STEMLESS GENTIAN. Fig. 1628. By the botanists of continental Eu. this is often split up into the 4 or 5 following species. The plants that Linnæus had in mind were probably mostly *G. Clusii* and *G. Kochiana.* For pictures of *G. acaulis* in its widest sense, see B. M. 52. G.C. III. 15:236. G.W. 3, p. 289. J.H. III. 52:59. R.B. 28:204. Gn. 48, p. 146; 54, p. 39. F.S. 23:2421, where a more detailed account of the 4 following species is given. A var. **Kòchii,** Hort., is known but it may well be *G. Kochiana.* A white-fld. form, var. **álba,** is advertised.

1628. Gentiana acaulis.

52. **angustifòlia,** Vill., not Michx. Stoloniferous: lvs. linear-oblong, narrowing toward the base, glistening above: fls. spotted with sprightly green; calyx-lobes more or less spreading, oval, abruptly contracted at the base. May, June. Limestone rocks, Alps.—Considered by Correvon the handsomest species of the whole genus.

53. **Kochiàna,** Perr. & Song. Lvs. large, flat, thin, spreading, oval or broadly oblong, light green: calyx-lobes oblong, limp, more or less contracted at the base and separated by truncate sinuses; corolla with 5 blackish green spots on the throat. May, June. Common in pastures on granitic Alps.—Dislikes lime. It seems almost certain that this is the *G. acaulis* var. *Kochii* of many gardeners.

54. **Clùsii,** Perr. & Song. A low acaulescent perennial perhaps not different from *G. acaulis* and so considered in "Index Kewensis:" lvs. lanceolate-acute, leathery: fls. dark blue; calyx-lobes pressed close against corolla, not contracted at base, and separated by acute sinuses. May, June. Limestone rocks, Alps.

55. **alpìna,** Vill. St. almost wanting: lvs. small, glistening, curving inward and imbricated, forming rosettes which incurve at about the middle: fls. dark blue. May, June. Granitic Alps.—This and *G. Kochiana* "require a compost of one-third crushed granite, one-third heath soil, and one-third vegetable loam, and should be planted on rockwork half exposed to the sun."

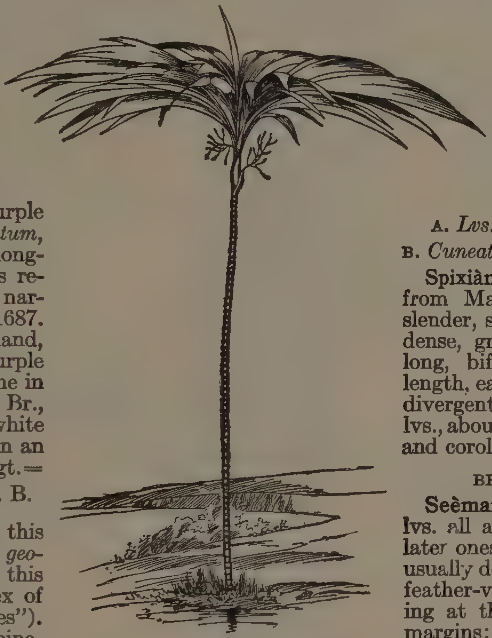
56. **dinárica,** Beck. Lvs. broad, thick, erect: fls. dark blue. Certainly a mere form of *G. acaulis,* but described as differing from that species in having no spots on the corolla. Alps of S. and E. Austria.

The following are names of gentians not sufficiently described for insertion above or as yet scarcely known in cult.: *G. arvernénsis,* Hort. Perhaps a var. of G. Pneumonanthe. Fls. Napoleon blue. See G.C. II. 20:40, desc. G. 29:7.—*G. Charpentièri,* Thom. Natural hybrid, intermediate between G. lutea and G. punctata: corolla spotted red; calyx 5-cut. Grisebach does not say whether the corolla is not plaited, anthers always free, and style none. Alps, above Engadine.—*G. corymbífera,* Hort., is described as 12–18 in. high, with usually simple sts. branching toward the top: fls. white, about 1 in. diam. New Zeal. G.C. III. 46:203.—*G. Fetisòwii,* Regel. St. erect, tall: fls. deep blue. China. Gt. 31:1069.—*C. Hǽngsiii,* Hausm.=G. Kummeriana.—*G. Késselringii,* Regel. Height about 8 in.: fls. whitish, dotted violet outside. Turkestan. Gt. 31:1087.—*G. Kummeriàna,* Sendt. Hybrid between G. lutea and G. Pannonica. Fls. yellowish.—*G. Láwrencei,* Burkill. Allied to G. ornata but distinguished by the much longer linear lvs.: corolla about 1¾ in. long, blue above, the tube paler with dark blue lines. Mongolia. G.C. III. 38:307.—*G. Wallichiàna.*—Height 8–12 in.: fls. clear blue.—*G. Walujéwi,* Regel & Schmalh. Fls. whitish, dotted pale blue. Turkestan. Gt. 33:1140.

WILHELM MILLER.
N. TAYLOR.†

GENUS, pl. **GENERA** (i. e., *kind*), is a term used in natural history to designate a group of species. As with species, so the genus is an indefinite conception, varying with the author. The chief value of the conception is its use in aiding us conveniently to arrange and name plants and animals. The name of the genus is the first of the two words in the name of the plant: thus, in *Brassica oleracea*, Brassica designates the genus, and oleracea the particular Brassica of which we are speaking. It is difficult to trace the origin of the genus-conception in natural history, but it is usually ascribed to Konrad Gesner (Zurich, 1516–1565). L. H. B.

GEODÒRUM (*gift of the earth*). *Orchidàceæ.* Orchids of minor importance, E. Indies to Austral., with radical lanceolate or elliptical lvs., tuberous bulb-like rootstocks, and vari-colored fls. in a nodding spike on the top of the scape; sepals and petals similar, lip upright: terrestrial. Belongs in the same sub-group or tribe as Cyrtopodium and Eulophia. In habit, they somewhat resemble Phaius and Eulophia, and require similar treatment, with potting in fibrous loam and peat. Apparently not offered in this country, but sometimes grown abroad in collections. *G. purpùreum*, R. Br., from India: like a Bletia in habit: lvs. large: scape erect, bearing a densely-fld. drooping raceme; fls. small, white with purple markings on the lip. *G. fucàtum*, Lindl., of Ceylon: 1 ft.: lvs. oblong-lanceolate and plicate, the scapes recurved at the apex: fl. with pink narrow sepals and ovate lip. B.R. 1687. *G. pictum*, Lindl., from New Holland, grows 1–2 ft., with dull rose-purple fls. shaded brown and white, borne in dense racemes. *G. dilatàtum*, R. Br., of India, 6–12 in. high, fls. white marked pink and yellow, borne on an erect scape.—*G. plicàtum*, Voigt.=Phaius. L. H. B.



1629. Geonoma Spixiana.

GEÒNOMA (Wittstein gives this interesting explanation: "Greek, *geonomos*, skilled in agriculture: for this tree puts forth buds at the apex of its stem which become new trees"). *Palmàceæ*, tribe *Arèceæ*. Slender spineless palms with ringed, reed-like stems much cultivated for their excellent decorative possibilities.

Leaves terminal or alternate, usually crowded in showy clusters; blade entire, 2-lobed at the apex, or more or less pinnatisect; segms. acuminate, 1-nerved, with the margins broadly recurved at the base; rachis acute above, convex on the back; petiole nearly cylindrical, concave at the base above; sheath tubular: spadices ascending or recurved, simple, forked or paniculately branched, slender or stout, often colored; spathes 2, often deciduous before flowering, or obsolete, the lower one partial, truncate, concave, the upper compressed or fusiform; fls. monœcious in each spadix, borne in the furrows of the spadix, at length partially exserted, when in 3's the upper one pistillate; cells of the anthers twisted: fr. small, globose, black.—Species about 100. Trop. Amer. G.C. II. 24:586. A.G. 16: 345. For *G. Ghiesbreghtiana*, see *Calyptrogyne*.

Several of the members of this extensive genus of small-growing palms are useful for the greenhouse, though most attractive while in a small state, from the fact that geonomas soon begin to form a stem, and when aged become rather scantily furnished specimens. These palms are by no means difficult to grow, and do not require a very high temperature, their natural habitat being the mountains of Central and South America, some of the species being found at an altitude of over 4,000 feet above sea-level. Geonomas form part of the undergrowth on their native mountains, and are said never to appear in the open country unsheltered by trees of larger growth; therefore, shade is necessary for them when cultivated under glass. The old practice of growing geonomas in a very light peaty soil does not seem to be the only method, for excellent results have been secured by growing them in a good loam, well manured and well drained, giving an abundance of water and a night temperature of 60.° Red spiders and thrips are the most troublesome insects to which these plants are subject, and both of these pests multiply much more rapidly if the plants are kept too warm and dry. (W. H. Taplin.)

The most useful species from a commercial point of view is *G. Riedeliana* (*G. gracilis*), which reminds one of *Cocos Weddelliana*, but has longer leaflets. The species are undoubtedly confused under cultivation, and often unidentified. They are said not to be grown in the open in southern California, at least, not to any extent. The species here listed appear to be those of most horticultural importance here.

A. *Lvs. simple, 2-lobed at the apex.*

B. *Cuneate-oblanceolate, rusty, tomentose.*

Spixiàna, Mart. Fig. 1629 (adapted from Martius' work on palms). St. slender, solitary, 6–9 ft. high: lvs. in a dense, graceful cluster; blades 3–5 ft. long, bifurcate one-fourth of their length, each lobe lanceolate-acuminate, divergent: spadix from between the lvs., about 3 ft. long; fls. small, the calyx and corolla equal. W. Brazil.

BB. *Cuneate-ovate, plicate.*

Seèmannii, Hort. Low, 1–3 ft. high: lvs. all alike, the first 2 in. long, the later ones 10 in. long, entire, or 2-lobed, usually deeply cleft at the apex, plaited, feather-veined; stalk triangular, sheathing at the base, with broad, scarious margins: fls. unknown. F.M. 1869:428. Cent. Amer.

AA. *Lvs. pinnate.*

B. *Basal lf.-segms. narrow; the upper ones the broadest.*

acaùlis, Mart. Acaulescent: lvs. in a congested, rosette-like cluster, long-petioled, 3–4 ft. high; blade unequally pinnatisect, with usually 6 segms. on both sides of the rachis; 22–25-nerved, basal segms. 4 lines wide, spreading, the middle and upper erect-spreading at an acute angle, ¾–4 in. wide, the apical very wide: spadix stiff, usually about 18 in. long, the stalk very thick; fls. numerous: fr. unknown. Cent. Brazil.

BB. *Broad and narrow segms. irregularly intermingled.*

C. *Blade of lf. 6 ft. long; petiole 1 ft. long.*

Pohliàna, Mart. St. 12–15 ft. high, slender, densely ringed, columnar or reedy: lvs. very numerous, erect or spreading, forming a much congested, showy cluster, in adult specimens; segms. very unequal, linear-lanceolate, falcate-acuminate, few-nerved and many-nerved intermixed, 16–20 in. long; petioles very short: spadix scarcely showing among the dense cluster of lvs. Trop. Brazil.—Cult. most advantageously in a warm moist house. The young specimens are attractive for potted plants.

cc. *Blade 2–2½ ft.: petiole 4 in. long.*

élegans, Mart., var. **robústa**, Drude. St. 6–10 ft. high, 3–4 lines diam.: segms. rarely 3, usually 5–7, 1-nerved, 10–14 in. long, some 4 lines wide, intermixed with broader, many-nerved ones, all long, falcate-acuminate: spadix about 10 in. long, the fls. very small, inserted in deep pits. Cent. Brazil.

bbb. *Lf.-segms. all alike (except the connivent apical ones).*

c. *Alternate, remote, linear, scurfy.*

Riedeliàna, Wendl. (*G. grácilis*, Lind. & André, the oldest and perhaps the correct name). Habit of *Cocos Weddelliana*, the whole plant sparsely covered with caducous, brown, shining scales: petiole slender, 1½ ft. or more long, terete below, flattened above; rachis triangular, bisulcate above: lvs. spreading, drooping at the apex; segms. 10–12 in. long, about 9 lines wide, linear-acute, elegantly recurved, the 2 terminal ones connivent: fls. showy, yellow, in long drooping spadices. Brazil. I.H. 21:169. B.M. 7963.

cc. *Equidistant: petiole half as long as the blade.*

Schottiàna, Mart. St. 9–15 ft. high, 1–1¼ in. thick: lvs. long-stalked, gracefully recurving; petiole half or more than half as long as the blade; segms. about 35 on each side, 10–12 in. long, ⅖in. wide, equidistant, linear or linear-lanceolate, very long-acuminate, recurved at the tip: spadix about 10 in. long, the stalk about 1 ft. long. E. Brazil.—A very variable species.

The following are imperfectly described, but are in the trade: *G imperiàlis*, Lind. G.W 2, p. 37.—*G. prínceps*, Lind.—*G. Pynærtiàna*, Hort. Belongs under A. One of the smallest lvs. measures 28 in. long by 10 in. at the broadest. Has not flowered yet, and the genus is therefore uncertain. R.H. 1898, p. 262. G.C. III. 23:258. F.E. 10:886. G.W. 2, p. 445.—*G. speciòsa*, Barb.-Rodr. G.W. 2, p. 431.—*G. Swártzii*, Griseb. (Calyptrogyne Swartzii, Hook. Calyptronoma Swartzii, Griseb.). Trunk 50–60 ft. high, smooth: lf.-segms. linear-acuminate, green, glabrous. Cuba.

N. Taylor.†

GEORGÌNA. A synonym of Dahlia, which still survives in the form of "Georginen," the popular name of dahlias in Germany.

GERÀNIUM (Greek, *crane;* from the resemblance of the fruit to a crane's bill). *Geraniàceæ.* Cranesbill. Generally herbaceous plants, annual, biennial, and perennial. Widely cultivated in borders, and some species in the rockery, usually caulescent.

Leaves simple, alternate or opposite and much-lobed, sometimes almost radical: fls. regular; sepals 5, imbricated, often 3-nerved and mucronate; petals 5, often hairy or ciliate; stamens 10, in 2 rows; anthers 10; seeds when ripened separated from the ovary and with its awn bent sinuously. The genus Erodium, its nearest ally, has but the inner row of stamens furnished with anthers and the awn of the seed is bent spirally. The geraniums of common speech are classed in the genus Pelargonium, having at the side of the pedicel a distinct narrow tube and zygomorphic fls.—The genus Geranium has over 250 species, found in the temperate zones particularly of the northern hemispheres, very few in the tropics. The roots of some, as *G. maculatum*, find use in medicine on account of their astringency. Thrive well in ordinary garden soil, and are propagated by seeds and divisions of roots. The best botanical account is that of R. Knuth in Engler's Das Pflanzenreich, hft. 53 (1912), and by Small and Hanks in N. Amer. Flora, Vol. 25, 1907, for the N. American species. A beautifully illustrated account of the genus is by Sweet (1820–30) in which special stress is laid on cultivation. There are 500 colored plates, and, where possible, these are cited in the following account, thus, S. 197.=Sweet, Geraniaceæ, plate 197.

Large masses of native species such as *G. maculatum* and *G. Robertianum* can be effectively naturalized under bushes and trees. They spread very rapidly and in the case of *G. Robertianum* will be profuse bloomers nearly all summer.

KEY TO THE SPECIES.

A. *Plants annual, more or less prostrate: lvs. finely dissected*................ 1. **Robertianum**
AA. *Plants perennial.*
B. *Species tender, to be grown only in greenhouse northward.*
C. *Foliage silvery canescent*.......... 2. **Traversii**
CC. *Foliage glabrous, at least never canescent*...................... 3. **anemonifolium**
BB. *Species hardy.*
C. *Tuberous-rooted*................. 4. **malvæflorum**
CC. *Not tuberous-rooted.*
D. *Plant with a thickened woody base*........................ 5. **macrorrhizum**
DD. *Plants without thickened woody base.*
E. *Foliage silvery-canescent.*
F. *Usually 1-fld*.............. 6. **argenteum**
FF. *Usually 2-fld*.............. 7. **cinereum**
EE. *Foliage or whole plant glabrous or pubescent, but not silvery.*
F. *Sts. erect.*
G. *Fls. dark blue, almost black.* 8. **phæum**
GG. *Fls. not dark blue, sometimes light blue.*
H. *Color of fls. white (see also white-fld. forms of Nos. 13, 15, and 16).*
I. *Lvs. 3–5-parted*....... 9. **Richardsonii**
II. *Lvs. 7-parted*.........10. **aconitifolium**
HH. *Color of fls. not white.*
I. *Mostly 1-fld*..........11. **sanguineum**
II. *Mostly more than 1-fld.*
J. *The st. branched.*
K. *Fls. rose-purple*....12. **Fremontii**
KK. *Fls. violet*.........13. **ibericum**
JJ. *The sts. essentially simple.*
K. *Lobes of the lvs. more or less rounded*..........14. **armenum**
KK. *Lobes of the lvs. ovate or lanceolate.*
L. *Pedicels recurved in fr*...........15. **pratense**
LL. *Pedicels erect in fr.*
M. *The pedicels not glandular*.....16. **maculatum**
MM. *The pedicels glandular.*
N. *Lvs. finely cut.*17. **incisum**
NN. *Lvs. 5-lobed*...18. **eriostemon**
FF. *Sts. decumbent or creeping, scarcely erect.*
G. *Peduncles 1-fld*...........19. **sibiricum**
GG. *Peduncles 2- or more-fld.*
H. *Petals about as long as the sepals.*
I. *Fls. pale lilac*.........20. **grandiflorum**
II. *Fls. rose-purple*.......21. **nepalense**
HH. *Petals 1–2 times the length of the sepals.*
I. *Upper lvs. 3-lobed*.....22. **Endressii**
II. *All the lvs. 5-lobed.*
J. *The petals striped*....23. **Wallichianum**
JJ. *The petals not striped, sometimes spotted.*
K. *Base of petals ciliate.*24. **collinum**
KK. *Base of petals pilose or glabrous*.......25. **Grevilleanum**

1. **Robertiànum,** Linn. Herb Robert. Red Robin. About 9 in. high: lvs. thin, ovate-orbicular, 3–5-parted, with 3-fid. pinnatifid lobes: peduncles slender, 2-fld.; fls. small, bright crimson. June to Oct. Amer., Eu., Asia and N. Afr. B.B. 2:341.—For the rockery, in a moist soil and some shade, and will carpet the ground in a few seasons, from seed. Annual; or possibly biennial.

2. **Tràversii,** Hook. A silvery canescant herb 3–15 in. tall with a stout st.: lvs. beautiful silver-color, nearly round, 7-parted, the lobes wedge-shaped, and 3-parted: fls. large, often 1½ in. across; sepals broadly ovate, cuspidate, silvery; petals ovate or nearly round, pale rose, or sometimes white, much longer than the sepals. Chatham Isl.—Not hardy north of Washington and to be grown in temperate house. Little known in Amer. but a desirable greenhouse plant.

1630. Geranium maculatum. (×⅛)

3. **anemonifòlium,** L'Her. (*G. canariénse,* Reut.). A stiff single-stemmed perennial from a thickened rootstock or tube: lvs. glabrous, round-ovate, 5-parted, the lobes finely dissected: fls. corymbose, the pedicels and calyx densely hairy; sepals oblong, mucronate, the mucro almost ½in. long; petals 2–3 times as long as the sepals, obovate, pale purple. Canary Isls. and Madeira. S. 244.—Must be grown in the temperate house, but doubtless hardy south of Washington.

4. **malvæflòrum,** Boiss. A usually 1-stemmed perennial, from a thickened tuber, not over 18 in. tall: lvs. long-petioled, 5–9-parted, the lobes finely dissected, hairy: fls. showy, the pedicels and peduncles densely hairy; sepals ovate-oblong, hairy; petals rose-purple, obcordate, the apex often emarginate, about twice as long as the sepals. Medit. Region.—Very doubtfully hardy north of Philadelphia.

5. **macrorrhìzum,** Linn. A large-rooted species, about 1½ ft. high, with a st. suffruticose at base: lvs. smooth, round, basal ones 5-lobed, cauline 3-lobed, toothed and often colored red: fls. in bunches at the end of the st.; calyx inflated; the sepals ovate and 3-nerved; petals spatulate and blood-red in color. May to July. S. Eu. B.M. 2420. S. 271.

6. **argénteum,** Linn. Silver-leaved Crane's-bill. About 3 in. high: lvs. almost radical, on long petioles, 5–7-parted, with 3-fid linear lobes, both surfaces hoary: peduncles almost radical, 1- or 2-fld.; fls. large, pink, with darker veins; petals emarginate. Middle of June to Aug. Carnic Alps. B.M. 504. L.B.C. 10:948. S. 59.—One of the best for the rockery. Often acts as a biennial in New England.

7. **cinèreum,** Cav. (*G. subargénteum,* Lange). Gray Crane's-bill. Like *G. argenteum,* but 2-fld. and paler in color: lvs. not so hoary in appearance. June, July. Pyrenees.

8. **phæum,** Linn. About 2 ft. high, with upright, short-haired st., glandular above: lvs. 5–7-lobed and deeply toothed: peduncles 1–2-fld.; petals spreading, obovate, unequally notched and often with a small spur, very dark blue, almost black, with white spot at base of each petal. May, June. Cent. and W. Eu.

9. **Ríchardsonii,** Fisch. & Trautv. About 1½ ft. high: lvs. thin and terminal, lobe of the uppermost lvs. longer than the often greatly reduced lateral lobes: pedicels conspicuously glandular pubescent; fls. large, white or sometimes streaked with pink; petals with long white hairs on inner surface. Colo. and west.—Sts. and young growth tinged with red.

10. **aconitifòlium,** L'Her. St. usually simple, grooved, 10–20 in. tall, few-lvd.: lvs. more or less hairy, deeply 7-parted, kidney-shaped or orbicular, the lobes broadly ovate, deeply pinnatifid, the segms. mucronulate: fls. fragrant, loosely corymbose, the pedicels 2-fld.; sepals oblong or oblong-ovate, 3-nerved; petals white, obovate, the margins slightly wavy. Alpine or sub-alpine region of Eu. June.—Useful chiefly as rock-garden species.

11. **sanguíneum,** Linn. About 1½ ft. high, with st. occasionally forked, erect: lvs. all petiolate, mostly 7-parted, with 3–5-lobed linear lobules: peduncles long, mostly 1-fld.; fls. very large, blood-red. June to Aug. Eu.—One of the best species in cult.

Var. **lancastriénse,** With. (*G. prostràtum,* Cav.). A dwarfer form, smaller and with less deeply lobed foliage: fls. lighter in color and conspicuously veined purple.

12. **Frèmontii,** Torr. & Gray. A 1- or many-stemmed perennial: lvs. nearly round, palmately 5–7-parted, the lobes 3-toothed or sometimes crenate, slightly hairy: fls. large and showy, frequently 1–1½ in. across; sepals oblong, 3-nerved; petals pale rose-purple, obovate, toward the base densely ciliate. Rocky Mts. G. 29:191.—A handsome garden species. Not as yet much known in cult. in Amer. but a fine showy geranium for the hardy border. Blooms all summer.

13. **ibéricum,** Cav. Iberian Crane's-bill. From 1–1½ ft. high: st. erect and leafless below, above dichotomously branched, villous: lvs. opposite, 5–7-parted, with deeply cut lobes and toothed lobules: fls. 1 in. across, in showy, open panicles, violet. July, Aug. Iberia. Gn. 71, p. 167. B.M. 1386. S. 84. Var. **álbum,** with white fls., is rare but known by some dealers.

Var. **platypétalum** (*G. platypétalum,* Fisch. & Mey.). Slightly shorter than the parent, with lvs. less deeply lobed and lobes less pointed: fls. deeper and richer in color, and also larger. G.M. 52:61. Gn. 76, p. 108. G. 3:293; 9:686.

14. **armènum,** Boiss. (*G. Backhousiànum,* Regel?). About 2½ ft. high, the lower part of the st. thickened and almost woody: lvs. radical, upright, orbicular, with 5 deep lobes: fls. about 1½ in. across, inclining to a dark crimson; petals dark spotted near the base, obovate, often with the tips a little recurved. All season at irregular intervals. Armenia. R.H. 1891: 350.—A very vigorous and floriferous species. Sometimes growing 4 ft. high.

15. **praténse,** Linn. Meadow Crane's-bill. About 2½ ft. high, with an upright round st.: lvs. mostly hand-shaped, with 7 lobes, each deeply cut: peduncles mostly 2-fld., drooping after flowering; fls. large, blue;

petals entire. June, through Aug. Eu. G. 18:649. G.L. 18:208. Gn.W. 24:367. Var. **flòre-plèno,** Not so tall as parent. Very numerous deep blue fls. in clusters. June and July, and often again in fall. J.H. III. 48:305. Var. **álbum,** a white-fld. form is known.

16. **maculàtum,** Linn. Wild or Spotted Crane's-bill. Fig. 1630. The common American species, about 1½ ft. high: st. angular: basal lvs. long-petioled, deeply 3–5-parted; st.-lvs. opposite, shorter-petioled: peduncles 1–5, infl. often umbellate; fls. 1–1½ in. broad, rose-purple; petals woolly at base. June, July. N. Amer. B.B. 2:341. S. 332.—Showy native species; should be more in cult. Grows best in somewhat wet places. Var. **plènum,** a double-fld. variety of deeper color. Var. **álbum,** a pale-fld. or pure white form is known.

17. **incìsum,** Nutt. (*G. eriánthum,* Lind.). About 1 ft. high, leafy branched, the st. thickened below, solitary: lvs. finely cut, long hairy, the hairs fine and silky: pedicels conspicuously glandular-pubescent; sepals oblong-lanceolate, mucronate; petals with stiff white hairs, inner surface purple, about 1 in. wide. Ore.—A hardy species well worth growing. Not perfectly hardy near Boston.

18. **eriostèmon,** Fisch. (*G. platyánthum,* Duthie). St. erect, slender, grooved, from an almost woody base: lvs. kidney-shaped, 5-lobed, sometimes palmately so, the lobes ovate, toothed, the teeth slightly mucronate: fls. corymbose, the sepals ovate, obtuse, very hairy; petals violet-purple, broadly obovate, entire. Native of Siberia and temp. China.—A showy and useful garden plant.

19. **sibíricum,** Linn. Siberian Crane's-bill. A slender, somewhat forked plant, brown-villous, 1–2 ft. high: lvs. deeply 3–5-parted: peduncles slender, usually 1-fld.; fls. very small, dingy white, the obovate petals scarcely exceeding the oblong-lanceolate 3-nerved sepals. June through Aug. Siberia, and naturalized near New York. B.B. 2:341. Jacq. Hort. Widd. pl. 19.—Another form under same name, with brick-red fls., appears to be in cult.

20. **grandiflòrum,** Edgew. A thick-stemmed perennial about 10–16 in. tall, usually somewhat glandular, branched: lvs. long-petioled, the blade 5-parted and rotund in outline, the lobes irregularly toothed: fls. bunched at the apex of the branches, showy; petals spreading, pale lilac, the veins dark purple, about as long as the sepals. N. Asia. F.S.R. 1:54. Gn. 64, p. 184.—Suitable mostly for rockeries.

21. **nepalénse,** Sweet. St. spreading or ascending, thin, not more than 18 in. long: lvs. ovate-rhomboid, deeply 5-lobed, hairy, the lobes dentate, the teeth almost spinose: fls. numerous, on hairy pedicels; sepals lanceolate, acuminate, often mucronate; petals usually about equaling the sepals, rose-purple, broadly obovate, not emarginate at apex. Mountains of Asia. June–Aug. S. 12.—Useful only in the rockery.

22. **Éndressii,** J. Gay. About 18 in. high, the st. covered with pale brown hairs: lvs. opposite, palmate, 5-lobed, upper ones 3-lobed, serrated, densely hairy, with spreading hairs: peduncles axillary, 2-fld.; petals entire, fringed at base, light rose, darker veined, 2–3 times the length of the 3-nerved, oblong-ovate sepals. Summer. Pyrenees.—Among the best for the border, and useful for cutting.

23. **Wallichiànum,** D. Don. Of prostrate trailing habit: st. and lvs. covered with silky hairs, the st. deeply grooved: lvs. light green, 3–5-parted, with deeply toothed lobes: fls. large, purple, borne sparingly all summer; sepals 3-nerved, the lateral nerves stiff-hairy; petals about twice as long as the sepals, smooth, emarginate. Himalayas. B.M. 2377. S. 90.—For the rockery and must not be grown in the open exposed parts of it. The hot dry winds of midsummer in E. U. S. are not favorable.

24. **collìnum,** Steph. (*G. Lóndesii,* Fisch.). St. angular and usually decumbent, grooved and hairy: lvs. palmately 5-parted, deeply divided and cut: sepals lanceolate-ovate, 3-nerved, densely hairy; petals entire, purple, with a tinge of violet. June, July. E. Eu.—One of the showiest in its season. Should be cut back before seeding, to induce second bloom.

25. **Grevilleànum,** Wall. St. creeping, rarely a little erect: lvs. long-petioled, the blades usually 5-lobed, kidney-shaped, hairy, the lobes deeply serrate, but not usually divided: flowering stalk thick, more or less glandular, the fls. large and showy, frequently 2 in. across; sepals oblong-ovate; petals obovate, sometimes hairy at their bases, pale rose or in some forms with large purple spots, at least as to the wild plant, 1–2 times the length of the sepals. Himalayas.—Useful for the rockery.

The following are unknown as to botanical affinities or are insufficiently known in Amer.

G. Balkànum, Hort. A hardy plant, with fragrant foliage: fls. on radical sts., 1 in. across, dark magenta. June.—*G. Heldreìchii,* Hort. Orange-colored fls.=(?).—*G. Lòwii,* Hort. 2–2½ ft.: fls. bright rose with violet center. Name unknown in botanical literature.—*G. prostràtum,* Hort. Fls. purple. Advertised as "good rockery subject."=(?).—*G. sylváticum,* Linn. About 2 ft. high, with a soft-haired, upright, round st.: lvs. 5–7-parted, lobes oblong, deeply toothed: fls. purple or violet. June, July. The common wood geranium of Eu. A white-fld. form *G. sylváticum álbum,* Hort., is known. Gn. 72, p. 178.—*G. tuberòsum,* Linn. Tuberous-rooted, 9–15 in. high, with st. at base naked: lvs. many-lobed, linear and serrate: pedicels 1–2-fld., fls. large, violet. May. S. Eu.

N. Taylor.†

GERANIUM, FEATHER: *Chenopodium Botrys.*

GERÁRDIA (after John Gerarde, 1545–1607, perhaps the most popular of the herbalists). *Scrophulariàceæ.* Hardy annual and perennial herbs, all American, and mostly of the Atlantic states, with yellow or rosy purple flowers, in late summer and autumn, the later color rarely varying to white.

Leaves mainly opposite: calyx 5-toothed or cleft; corolla bell- to funnel-shaped, broad-throated, 5-parted, the 2 posterior lobes often smaller and more united; stamens commonly more or less hairy; anthers more or less approximate in pairs: caps. globose, 2-grooved; seeds usually angled, loose-coated. The first 3 species described below belong to a section in which the roots are more or less saprophytic; by some, and probably correctly, they are considered as belonging to the genus Dasystoma. These plants are therefore rather difficult to cultivate, and are offered only by collectors. *G. tenuifolia* is offered by one dealer, the seeds presumably gathered in European gardens.

A. *Fls. yellow.*

B. *Corolla pubescent outside: biennial or annual.*

Pediculària, Linn. St. much branched: pubescence partly glandular and viscid, especially on the pedicels and calyx, while in the next 2 species there is no glandular pubescence: lvs. 1-2 in. long, all pinnatifid: fls. in loose panicles or solitary, the calyx-lobes oblong and herbaceous, usually incised. E. N. Amer.

BB. *Corolla glabrous outside: perennial.*

C. *Height 3–6 ft.*

virgínica, Linn. (*G. quercifòlia,* Pursh). St. at first glaucous, sparingly branched: lower lvs. 3–5 in. long, 1–2-pinnatifid; upper lvs. rarely entire: calyx-lobes ovate, entire. Dry woods, E. U. S.

CC. *Height 1–2 ft.*

lævigàta, Raf. Not glaucous but glabrous, the st. simple or slightly branched: lvs. 1½–4 in. long, entire, or the lowest somewhat incised, all petioled, lanceolate or ovate-lanceolate: calyx-lobes ovate-lanceolate, equaling or shorter than the tube and caps. glabrous, about twice as long as the calyx. Oak barrens, etc. S. E. U. S.

AA. *Fls. rosy purple rarely varying to white.*

B. *Height 1 ft.*

tenuifòlia, Vahl. Height 1 ft.; branching, paniculate: lvs. mostly narrowly linear: infl. racemose; corolla ½in. long, light purple, spotted, sometimes white. Low or dry ground, E. N. Amer.

BB. *Height 2–3 ft.*

linifòlia, Nutt. Perennial: lvs. erect, very narrowly linear, 1 line wide: calyx-teeth minute; corolla 1 in. long. Low pine-barrens, N. Amer. Not cult., but said to be a parent with *Pentstemon pulchellus* of **G. hýbrida,** Hort. Intro. by Haage & Schmidt, 1899. The poor cut in S. H. 2:485 seems nearer Pentstemon than Gerardia.

Wilhelm Miller.

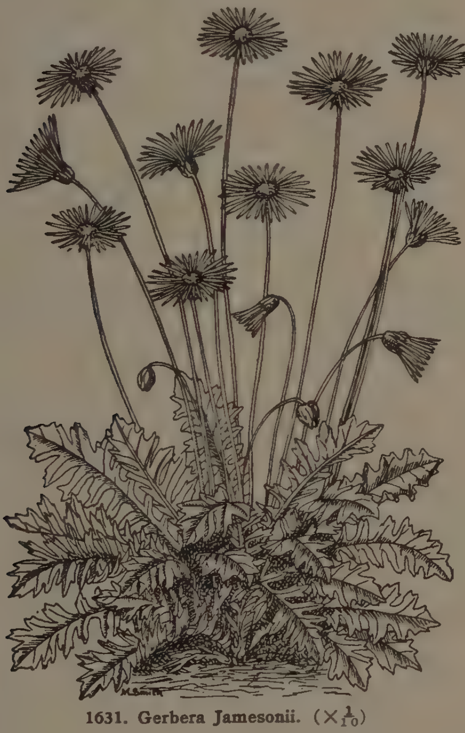
GERBÈRA (named in honor of Traug. Gerber, a German naturalist who traveled in Russia). *Compósitæ.* A small group of temperate and tropical Asiatic and African perennial herbs grown for their yellow or pink or orange flower-heads.



1631. Gerbera Jamesonii. ($\times\frac{1}{10}$)

Stemless herbs with radical, petioled lvs. which are entire or sometimes lobed: fl.-heads solitary, many-fld., the conspicuous rays in 1 or 2 rows, those of the inner row, when present, very short and sometimes tubular and 2-lipped, as are the disk-fls.: achenes beaked.—There are 40 species, only one of which (*G. Jamesonii*) is well known in Amer. and is sometimes found outside the collections of botanic gardens and fanciers. They should be grown in the temperate house, in a rich compost of sandy loam and peat. Prop. by seeds or by cuttings of side shoots.

Jàmesonii, Hook. Fig. 1631. Hairy throughout, the mature lvs. very woolly beneath: lvs. numerous, the petiole 6–8 in. long, the blade 5–10 in., a little pinnatifid: heads solitary, the showy orange-flame-colored rays strap-shaped. Transvaal. B.M. 7087. G.C. III. 5:773. Gn. 36:340. A.G. 22:345. Gt. 54:1545. G.W. 2, p. 2. R.H. 1903:36.—Could be grown outdoors in the S. A brilliant summer-blooming composite, more or less planted in the open. Var. **transvaalénsis,** Hort. Has larger fl.-heads than type, of somewhat lighter color. Var. **illústris,** Hort. A robust variety.

G. aurantìaca, Sch. A handsome plant with fls. 2½ in. diam.: florets red, with bright yellow anthers. Natal and the Transvaal. B.M. 8079. Has been listed under name of G. Elsæ.—*G. cantabrigiénsis,* Hort. A garden hybrid between G. Jamesonii and G. viridifolia G.M. 47:366, desc.—*G. viridifòlia,* Sch., is a little-known green-lvd. plant with showy fls. that are white on the upper side, yellow beneath. S. Afr.—Well worth growing in temperate house.

N. Taylor.

GESNÈRIA (Conrad Gesner, Zurich, 1516–1565, celebrated naturalist, and considered to be the originator of the idea of genus in taxonomy). *Gesneriàceæ.* Greenhouse and hothouse plants with showy tubular flowers. Sometimes written *Gesnera.*

Low perennials, sometimes shrubs, with simple, opposite lvs. and showy tubular fls. in terminal short panicles or fascicles: calyx campanulate, 5-parted; corolla long, straight or curved, more or less ventricose, the base often distinctly swollen or gibbous, the limb mostly shallow-toothed and nearly regular or bilabiate; stamens 4, didynamous (in pairs under the upper lip); style 1, long; glands on the disk in the fl.—Species upward of 40, in the American tropics. Often tuberous plants; allied to Achimenes, Gloxinia, Isoloma and Streptocarpus. Some of the gesnerias of the trade belong to Nægelia, which differs, amongst other things, in having an annular or ringed disk rather than a disk of distinct glands. There is considerable variation of opinion as to the limits of Gesneria. In this account, the genus is held to include Pentarhaphia, Duchartrea, Codonoraphia, Conradia, Ophianthe, Synanthera. The plants of this group are probably considerably modified by crossing and breeding. The catalogue name *G. hybrida* probably covers some of these forms.

A. *Lvs. green.*

cardinàlis, Lehm. (*Dircæa cardinàlis,* Regel. *G. macrántha,* Hort.). St. 6–12 in. high, stout, and hairy: lvs. large, cordate-ovate, crenate-dentate, petioled: fls. red, tubular, hairy, slender (2–3 in. long), the upper lip projecting and the lower one almost wanting, borne in a terminal, more or less flat cluster. Nativity unknown. B.M. 8167. Gn. 42:232. A good species for the stove.—*G. Duvàlii,* Hort., is evidently only a slender form of this species.

Héndersonii, Hort. Lvs. velvety green: fls. 3 in. long, brilliant scarlet, in a large truss. Probably of garden origin.

longiflòra, Hort., is a small-lvd. species, with drooping, long-tubed nicotiana-like white fls. Gn. 33:340.—The botanical position of this plant is in doubt. It is not the *G. longiflora,* HBK., which is purple-fld., nor *G. longiflora,* DC., which is *Achimenes longiflora.* By some it has been confounded with *Isoloma longifolium,* Decne. *Pentarhaphia longiflora,* Lindl. (*Gesneria ventricosa,* Swartz), is a small somewhat branched shrub: lvs. ovate-lanceolate or oblong-lanceolate, acuminate and serrulate, pale green beneath: fls. bright scarlet, 1½ in. long, in long-peduncled cymes; corolla-tube somewhat curved, narrowed toward the base; stamens red, much exserted. W. Indies. B.M. 7339.—A good summer- and autumn-blooming stove shrub.

AA. *Lvs. richly colored, at least beneath.*

libanénsis, Morr. (*Pentarháphia libanénsis,* Hanst. *Rhytidophýllum floribúndum,* Van Houtte. *Ophiánthe libanénsis,* Hanst.). Subshrub, but only a few inches high, simple or slightly branched: lvs. more or less rosulate toward top of st., 3–4 in. long, obovate-lanceolate, more or less blistered, toothed: fls. bright red, half as long as lvs., tubular, puffed or swollen in the middle, hairy, the mouth oblique and the limb of 5 small ciliated lobes; stamens equaling the tube; calyx very short, the segms. leafy. Cuba. B.M. 4380.

craniolària, Swartz (*Pentarhàphia craniolària,* Decne.). Three to 4 ft. somewhat shrubby: lvs. glabrous above and hispid beneath, obovate-cuneiform, runcinate or more or less lobed: fls. greenish yellow with black dots, in long-peduncled clusters of 5 or 6, the corolla-lobes fringed. St. Domingo.

Lèopoldii, Scheidw. Compact: st. erect from the large, depressed tuber, thinly hairy: lvs. verticillate in 4's, broadly ovate-acuminate, more or less unequal at base, dentate, green above and purple beneath: fls. long-tubular, thinly hairy, the lobes nearly equal; light scarlet, in a rather loose, umbel-like cluster. Nativity not recorded. F.S. 7:704, 705. Gn. 53:542.

exoniénsis, Hort. Hybrid: lvs. velvety, with red and purple hairs: fls. bright orange-red, yellow in the throat, in close clusters: 1 ft.

1632. Geum rivale.

refúlgens, Hort. Probably a hybrid: lvs. cordate-ovate, red-hairy: fls. deep red or vermilion: 1½ ft.—One of the best.

Donkelæriàna, Lem. (*G. Dónklarii,* Hort.). St. often 2 ft. tall: lvs. large, cordate-ovate, crenate, hairy, green and purple-tinged above and purple beneath: fls. tubular-campanulate, the rounded lobes nearly equal, dull red, 2 in. long, hanging from long pedicels in a large panicle. Variable. Colombia. B.M. 5070. R.B. 21:97. F. 1853:241.

G. amábilis, Hort.=Nægelia.—*G. cinnabarìna,* Lind.=Nægelia.—*G. guatemalénsis,* Hort., "a free grower and bloomer, fls. orange," was once offered.—*G. jasminiflòra,* Hort., "fls. of the purest white, freely produced, beautiful," once offered.—*G. oblònga,* Hort., fls. orange.—*G. oblongàta,* Hort., is probably the same and is very likely an Isoloma.—*G. Regìnæ,* Hort. Exhibited abroad: lvs. green and velvety, the midrib and main veins white: fls. bluish purple.—*G. robústa,* Hort., "vermilion, beautifully spotted and tigered."—*G. Seèmannii,* Hook.=Isoloma.—*G. zebrìna,* Paxt.=Nægelia.

L. H. B.

GETHÝLLIS (old Greek name, of no particular application). *Amaryllidàceæ.* Nine or 10 stemless herbs, with the look of crocus, allied to Sternbergia, from the Cape region, seldom cult. under glass; apparently not in the trade: lvs. usually appearing after the fls., linear, sometimes filiform and twisted: fls. appearing through the ground, of delicate texture and of short duration, fragrant, whitish, salverform, with a long slender tube and 6 similar acute spreading segms.; stamens 6 or more, attached in the throat; ovary 3-celled, concealed in the bulb-neck: bulbous. Prop. by offsets or seeds. *G. áfra,* Linn. Bulb 1½–2 in. diam.: lvs. 12–20, linear and twisted: fl. with whitish limb 2 in. or less long and tube 3–4 in. long; stamens 9–12: fr. yellowish, clavate, recorded as edible. B.R. 1016. *G. spiràlis,* Linn. Bulb 1–1¼ in. diam.: lvs. 4–6, linear-subulate, very much twisted, 4–6 in. long; perianth-tube 2–3 in. long, limb 1–1½ in. long, whitish and tinted red on the outside; stamens 6: fr. clavate, 2–3 in. long. B.M. 1088. *G. ciliàris,* Linn. Bulb 1½ in. diam.: lvs. 20 or more, linear, twisted, prominently ciliate: perianth-tube 2–3 in. long, the whitish limb ½in. long: fr. yellow, clavate, 2–3 in. long.

L. H. B.

GÈUM (probably originally from Greek, *geuo,* to have a taste; referring to the roots). *Rosàceæ.* Hardy border and rock plants, some of which are valued for their bright red flowers, some for their pure yellow flowers, others for their long plumy fruits.

Herbs, with a perennial rhizome, sometimes stoloniferous: root-lvs. crowded, odd-pinnate, the alternate lobes often smaller, terminal ones largest; st.-lvs. few, mostly of 3 lfts. or bract-like: fls. 1–2 in. across, solitary or corymbose or cymose; calyx persistent, its tube nearly hemispheric, usually 5-lobed; petals 5, nearly or quite round, longer than the calyx: fr. bunched on a short receptacle, frequently plumed.—More than 50 species, mostly in temperate and frigid regions.

The plumy kinds are all contained in the subgenus Sieversia. *G. chiloense* is the best species, and in the gardens is commonly seen in double forms. A gardener writes that "inferior forms show scarcely any duplicity." Geums are of easy culture, and are propagated by division or seed. It is said that they hybridize freely if grown together. The dwarf kinds are suited only to the rockery. Correvon, of Geneva, Switzerland, writes that *G. reptans* is one of the best of the rockery kinds, and needs full sunlight. For *G. triflorum* he advises half exposure to sun and a light, moist soil. *G. rivale* grows naturally in marshy places.

A. *Plumy geums: style in fr. long and plumose*

B. *Fls. yellow.*

C. *Plants spreading by runners.*

réptans, Linn. Root-lvs. interruptedly pinnatifid; upper lvs. 3-lobed, deeply crenate-serrate: fls. erect; petals obcordate, not much longer than the sepals. Eu. Gn. 45:284.—The purple styles are pretty.

CC. *Plants not spreading by runners.*

D. *Root-lvs. pinnatifid.*

montànum, Linn. An erect and single-fld. perennial with lower lvs. lyrate pinnatifid; terminal lft. broadly ovate-rounded: calyx-lobes entire, while those of *G. reptans* are often 3-cut at apex; petals 1–2 times the length of the sepals. S. Eu. G.C. II. 13:425. Gn. 45, p. 285.—Under the name of *G. Heldreichii* and *G. Heldreichii superbum* are advertised what appear to be forms of this with orange-colored fls. which often produce more than 1 fl. The name Heldreichii is of no botanical significance. G.M. 46:371.

DD. *Root-lvs. kidney-shaped.*

radiàtum, Michx. (*Sievérsia Péckii,* Rydb.) Very hirsute: root-lvs. 2–5 in. broad: st. 1–8-fld.: bractlets minute. Mountains of N. C. and Tenn.

BB. *Fls. bright red, unmixed with yellow.*

C. *Lateral lobes of lvs. minute.*

coccíneum, Sibth. & Smith, not Hort. "St.-lvs. 3-lobed; root-lvs. lyrate, the terminal lobe largest, cordate-reniform: fls. erect. Mt. Olympus in Bithynia." The above is an exact translation of the entire description given by Sibthorp and Smith, Flora Græca, t. 485.—The chances are that all the plants in the trade under this name are really *G. chiloense.* The true *G. coccineum* is known in the botanic gardens.

CC. *Lateral lobes of lvs. 1 in. long.*

chiloénse, Balb. (*G. coccineum,* Hort., not Balb.). "St.-lvs. 3-parted, laciniate; root-lvs. interruptedly lyrate, pilose: terminal lobe rotund, somewhat 3-lobed, crenate: fls. panicled: carpels villous." The above is a literal translation of B. R. 1348, where the terminal lobe is shown to be 2½ in. each way. Chile. B.R.

1088, and under 1099. L.B.C. 16:1527. Gn. 14:562; 45, p. 284. R.H. 1890, p. 305; 1881, p. 309. G. 4:487. All erroneously as *G. coccineum.*

Var. **miniàtum,** Hort. (*G. miniàtum*, Robt. Parker), has fls. about two shades lighter in color. A robust form growing 2–3 ft. high, easily prop., and fls. from April to end of July. Gn. 38:298, where it is supposed to be a hybrid of *G. chiloense* var. *grandiflorum* × *G. aureum*, which is a robust many-fld. form of *G. montanum* or else of *G. chiloense* × *G. urbanum.*

Var. **grandiflòrum,** Hort., is an improved form. "The double-fld. form of this seems to be a more general favorite, the blooms lasting longer, though I think they lack the elegance of those of the simple form. They begin to expand soon after May and are produced until Oct."—D. K., in Gn. 38, p. 299. Var. **plènum,** Hort., a semi-double form, is known. It has bright scarlet fls. and is a good border plant. G. 10:495.

BBB. *Fls. chiefly dull red, mixed with yellow.*

triflòrum, Pursh (*Sievérsia ciliàta*, Pursh). Low, softly hairy: lfts. very numerous and crowded, deeply cut: fls. 3 or more on long peduncles; calyx purple, as long as the petals. Coulter says the petals are erect. Arctic Amer. L.B.C. 17:1609. Fruit showy and interesting all summer.

AA. *Not long and plumy in fr.*

B. *Style jointed and bent in the middle.*

C. *Fls. purplish orange.*

rivàle, Linn. Fig. 1632. St. erect and nearly simple: root-lvs. lyrate; st.-lvs. few, with 3 lobes or lfts.: calyx brownish purple; petals purplish orange, obovate and emarginate, narrowed into a claw. North temperate regions. Var. **álbum,** is also sold.

CC. *Fls. golden yellow.*

macrophýllum, Willd. St. erect and hairy: lower lvs. pinnatifid, 3–7-lobed, often with small lfts. irregularly placed on the rachis: fls. several, short-peduncled. E. N. Amer. B.B. 2:221.

BB. *Style not jointed, straight.*

Róssii, Seringe. Slightly pubescent above: scape 1–3-fld.; styles glabrous. Colo., arctic regions.—Fls. large, bright yellow.

G. atrococcíneum, Hort., may be a typographical error for G. atrosanguineum.—*G. atrosanguíneum*, Hort., is presumably a form of G. chiloense, with darker fls. than the type, and sold mostly if not entirely, in its double condition.—*G. bulgáricum*, Hort.=(?). *G. Éwenii*, Hort. has light orange fls. and is said to be a good border plant.—*G. japónicum*, Thunb., is sold, but little known. St. flexuose, hirsute: lvs. 3–5-lobed, hirsute: fls. erect, yellow; petals as long as the calyx: fr. hirsute, awned, recurved. Japan.

WILHELM MILLER.
N. TAYLOR.†

GEVUÌNA (from the Chilean name). Also written *Guevina. Proteàceæ.* One species, **G. Avellàna,** Molina (Syn., *Quádria heterophýlla*, Ruiz & Pav.), sparingly planted in Calif. CHILEAN NUT. CHILE HAZEL. An evergreen tree, with large, alternate odd-pinnate, dark green, glossy lvs. and white, hermaphrodite fls. in long, axillary racemes: sepals 4, deciduous; stamens 4; ovary nearly sessile, 1-celled and 2-ovuled, the style filiform: fr. a somewhat fleshy drupe, about the size of a cherry, coral-red when ripe, the seed having a pleasant-flavored kernel, resembling the hazel in taste and largely used by the Chileans. G.C. III. 40:174. Prop. by seeds or by green cuttings under glass. No trees of bearing age recorded in U. S., although a tree approximately 50 years old is recorded as bearing in Devonshire, England.

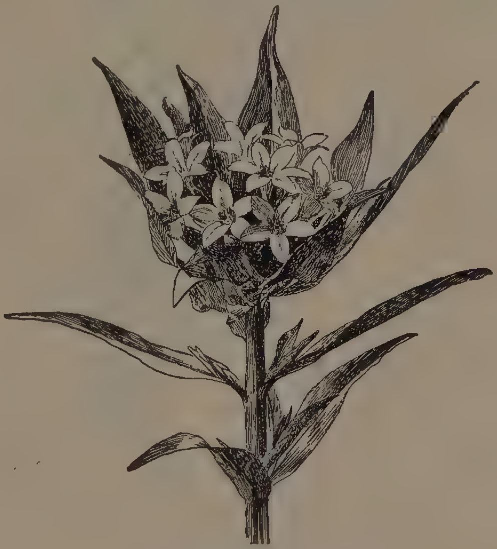
W. A. TAYLOR.

GHERKIN: A small cucumber. The Burr or West Indian gherkin is *Cucumis Anguria.*

GÍFOLA (anagram of *Filago*). *Compósitæ.* About 10 species of small woolly composites, of no horticultural significance, in warm and temperate countries. *G. germánica*, Dum. (*Fílago germánica*, Linn.), the COTTON-ROSE, is a cottony annual plant somewhat like leontopodium, which latter is now and then collected by tourists and dyed like immortelles. It was called *Herba impia* by the old herbalists, because a new generation of clustered heads rises out of the parent cluster as if undutifully exalting itself. It is native in Eu., and has become naturalized in E. N. Amer. in dry fields. St. erect, 6–18 in.: lvs. lanceolate, upright, crowded: heads small, rayless.

GÍLIA (Philipp Salvador Gil, Spanish botanist of the latter half of the eighteenth century, collaborator with Xaurez). *Polemoniàceæ.* Annual, biennial or perennial herbs, mostly of western North America.

Flowers small, of many colors, the corolla funnelform to bell-shape or sometimes salverform, 5-lobed; stamens 5, inserted near the base of the corolla-tube, the filaments usually naked; ovary 3-loculed, with axile placentæ, the stigmas 3 (or sometimes 2).—Nearly 100 species, as the genus is now understood by most botanists. Gilia is a very polymorphic genus, into which Gray now (Syn. Fl. 2, pt. 1, suppl.) throws Collomia, Linanthus, Leptosiphon, Leptodactylon, Navarretia, Hugelia, Ipomopsis, Fenzlia. In this conception, Gilia is defined as follows: "Fls. naked, not involucellate; calyx partly herbaceous, scarious below the sinuses; lobes narrow and acute; corolla salverform or funnelform to campanulate or almost rotate; filaments not bearded at base: seeds wingless: herbs, or a few suffruticose." In cult. only *G. californica* is woody. It is not certainly hardy in the E.



1633. Gilia grandiflora. (×¾)

Several of the gilias are popular garden annuals or biennials (a few perennial). They are of the easiest culture, being vigorous, hardy and floriferous. They are mostly dwarfish, and are excellent for low masses, edgings or rockeries. Seeds may be sown where the plants are to grow. Any good soil will suit them.

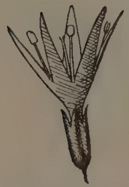
A. *Plants not shrubby.* (Nos. 1–17.)

B. *Lvs. normally alternate, entire or pinnately cut or divided (lower lvs. sometimes opposite).*

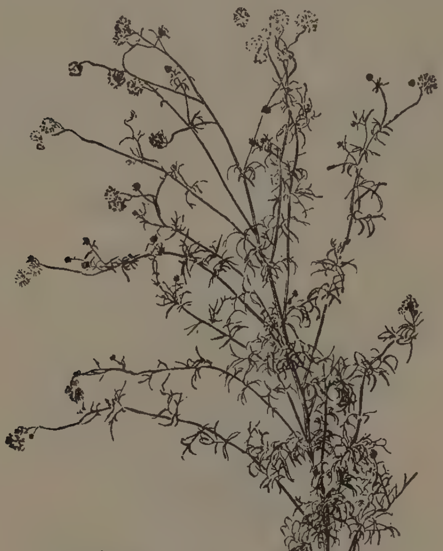
C. *Fls. in dense heads, which are subtended by leafy involucres.*

D. *Foliage entire or at least not much parted.*

1. **grandiflòra,** Gray (*Collòmia grandiflòra,* Douglas). Fig. 1633. Erect, with minutely pubescent reddish sts. 1–2 ft. high: lvs. linear-lanceolate or oblong, narrowed below but scarcely petioled, entire, acute: fls. many, in dense terminal heads, buff or salmon-color, redder inside, 1 in. long. Plains, west of Rocky Mts. B.M. 2894. B.R. 1174.—This and the next are interesting annuals. Useful as bee plants.



1634. Flower of Gilia capitata. (×2)



1635. Gilia achilleæfolia. (×¼)

2. **coccínea,** Gray (*Collòmia coccínea,* Lehm.). More slender: sts. not red: lvs. narrower (mostly linear), somewhat cut at the ends: fls. smaller, slender-tubed, yellow or buff outside and brick-red inside. Chile. B.R. 1622.

DD. *Foliage pinnately parted or compound.*

3. **mínima,** Gray (*Navarrètia mínima,* Nutt.). Dwarf and tufted (3 in. or less high) often forming broad tufts, nearly glabrous: lvs. needle-like, pinnately parted: fls. white, the corolla scarcely exceeding the white-hairy calyx. In arid districts. Dak. to Ore. and Colo.

4. **congésta,** Hook. A foot or less high, erect or spreading, tufted: lvs. mostly 3–7-divided into linear divisions: fls. corymbose or in close head-like cymes; corolla white, the oval lobes nearly as long as the tube; calyx-teeth long-pointed, nearly equaling the corolla. A small-fld. species growing from Rocky Mts. to the Pacific.

CC. *Fls. not in close heads, but more or less scattered, or if capitate, the heads not leafy-subtended.*

D. *Plant perennial: seed only 1 in a locule: fls. small.*

5. **débilis,** Wats. Two in. or less high: lvs. oblong, entire or 2–3-lobed, petioled: fls. solitary and nearly sessile, the purple corolla ⅔in. long, the tube exceeding the calyx. S. Utah.—Offered by collectors, but little known in cult.

DD. *Plant annual: seeds more than 1 to the locule: corolla distinctly tubular, but relatively small.*

E. *Infl. capitate.*

6. **capitàta,** Douglas. Fig. 1634. Plant 18 in. to 2½ ft. tall, the sts. long and nearly straight between joints: fls. about ½in. long, in dense, nearly globular heads, which terminate long, naked sts.; corolla-lobes lance-linear, acute: lvs. cut into very unequal linear lobes. Calif. and Ore. B.M. 2698. B.R. 1170. G.W. 15, p. 214.—An old favorite. There is a white form (var. **álba**). There is also a var. **màjor.**

7. **laciniàta,** Ruiz & Pav. Much like the last in botanical characters, and possibly a form of it: lower and much more slender, the lf.-divisions mostly very narrow (usually almost thread-like), the heads smaller or the fls. sometimes even scattered. Chile.—The fine foliage and compact habit make this species an excellent garden plant.

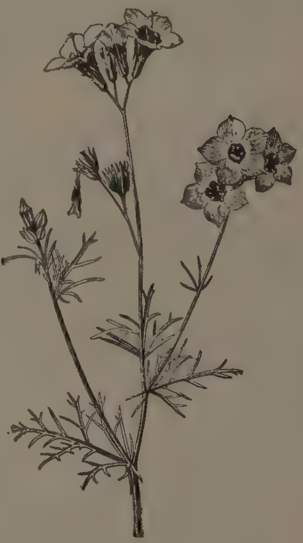
EE. *Infl. mixed, capitate on the main branches, scattered on the others.*

8. **achilleǽfolia,** Benth. Fig. 1635. Stout (2–3 ft.) and very branchy and bushy, the early main branches terminating in large, dense heads, but the later, finer growth bearing scattered fls.: lvs. small, with short, linear lobes or teeth: fls. large, violet or purple-blue, the corolla-lobes oblong or obovate: caps. large. W. Calif. B.M. 5939 (showing only capitate infl.).—An old garden plant. Fls. vary to white and rose, and there is a large-fld. form. Various horticultural names are in use for these forms, such as *álba, ròsea, màjor,* etc.

9. **multicaùlis,** Benth. Not unlike the preceding, from which it differs only in its smaller fls. and more distinctive habit. Calif. B.M. 3440 and B.R. 1682, both as *G. achilleæfolia* from which this may not really differ.

EEE. *Infl. scattered or loosely cymulose.*

10. **trícolor,** Benth. Fig. 1636. A very diffuse, twiggy grower, 2–2½ ft. high, sparsely pubescent: lvs. few on the full-grown plant, small, with many short, very narrow or needle-shaped divisions: fls. comparatively large (¾in. long or nearly so), nearly or quite bell-shaped, the corolla 2–3 times the length of the calyx; color of the roundish lobes violet and passing to whitish at the base, of the throat brown-purple and of the tube yellow. W. Calif. B.M. 3463. B.R. 1704.—One of the commonest of garden annuals. There is a white form (*G. nivàlis,* Hort. *G. álba,* Hort.), Gn. 72, p. 201, and a rose-colored form (*G. ròsea,* Hort.), and a red-violet form (var. *rùbro-violàcea,* Hort.) Besides these a small form has been called *G. nàna,* a large one *G. spléndens,* and a dense, stiff one *G. compácta.* None of these names appears to be in anything but trade catalogues. Thrives with the least care, and is always a profuse bloomer. It requires an open warm situation.



1636. Gilia tricolor. (×½)

DDD. *Plant biennial: seeds few or many in each locule: fls. large and long-tubular, red (running into white forms), the corolla very much surpassing the subulate calyx-lobes. (Ipomopsis.)*

11. **coronopifòlia,** Pers. (*Ipomópsis élegans,* Poir. *I. auranttaca* and *I. sanguínea,* Hort.). Standing Cypress. St. strict and unbranched, sometimes 6 ft. high, very leafy: lvs. pinnate, the divisions needle-like and about 1 in. long: fls. many, 1½ in. long, long-trumpet-shape, borne along the sides of the summit of the st., the calyx inconspicuous amongst the short bract-lvs., the corolla scarlet or pink-red and dotted and yellowish within, varying to orange, its lobes obtuse or nearly so and flaring. In dry soil, S. C., south and west. B.R. 1691. G.C. III. 40:277. G.M. 49:598. Gn. 70, p. 165.—Common old garden plant, and worthy. Fls. scentless. Name should probably be *G. rubra,* Heller.

1637. Gilia liniflora. (×⅜)

1638. Gilia micrantha. (×½)

12. **aggregàta,** Spreng. (*Ipomópsis élegans,* Lindl.). Differs in mostly shorter stature, pubescent st., and more slender habit, with redder (sometimes white) fragrant fls., with acute and reflexing corolla-lobes. Neb., south and west. B.R. 1281.—The fls. are fiery scarlet or sometimes nearly white. A very showy biennial.

BB. *Lvs. opposite, entire, or, if alternate (as in No. 13) palmately parted.*

C. *Foliage very fine, the lvs. cut into thread-like or linear divisions.*

D. *Corolla rotate-bell-shape, with a short, flaring tube.*

13. **liniflòra,** Benth. (*G. linifòlia,* Hort.). Fig. 1637. Ten to 20 in. high, diffuse and branchy: lower lvs. mostly opposite, but the upper alternate, all palmately divided to the base in needle-like or spurrey-like divisions: fls. rather large for the size of the plant, the corolla white or blush, nearly rotate, the thin lobes obtuse. Calif. B.M. 5895.—A useful tufty garden annual. The name *liniflora* is meant to designate the resemblance of the fls. to those of *Linum tenuifolium;* but some catalogue-maker, evidently thinking that the name meant *linear-flowered,* and was therefore inappropriate or an error, has changed the name to *G. linifolia,* under which name it is known in the trade.

1639. Gilia dianthoides, the Fenzlia of gardens.

DD. *Corolla salverform, with a filiform and elongated tube. (Leptosiphon.)*

14. **densiflòra,** Benth. (*Leptosìphon densiflòrus,* Benth.). Erect or even strict, 1–2 ft., hairy: lvs. with many filiform somewhat rigid divisions: fls. in rather close heads, lilac or white, ½–¾ in. long; tube of the corolla scarcely longer than the lvs.; lobes of the corolla spreading, obtuse, often dentate, nearly or quite as long as the tube. Calif. B.M. 3578. B.R. 1725.—Common garden annual. The white-fld. form is known as var. **álba,** Hort.

15. **androsàcea,** Steud. (*Leptosìphon androsàceus,* Benth.). Much like the last, but the tube very slender and much exserted beyond the calyx and lvs.: fls. 1 in. long, pink, lilac or white, in rather close heads, the corolla-lobes ovate-acute and entire, much shorter than the tube, 12–18 in. Calif. B.M. 3491. B.R. 1710.

16. **micrántha,** Steud. Fig. 1638. Tufted, 8 in. or less high, the sts. most leafy near the top: lvs. short, fascicled: fls. with an exceedingly slender thread-like tube which is 1–1½ in. long, and projecting prominently above the upper fascicles of lvs., the corolla-lobes spreading and obtuse; color range very wide,—from purple to lilac, red, yellow and white. Calif.—A popular bedding plant. Forms of it are known as *Leptosiphon aureus, L. carmineus, L. hybridus,* and *L. roseus.*

CC. *Foliage of entire (but narrow) lvs.*

17. **dianthoìdes,** Endl. (*Fénzlia dianthiflòra,* Benth.). Fig. 1639. Tufted, 6 in. or less high: lvs. narrowly linear, opposite: fls. 1–1½ in. long, lilac or purple, with yellowish throat, the flat-spreading lobes denticulate or nearly fringed. S. Calif. B.M. 4876. R.H. 1865:11.—A choice little annual, excellent for edgings and rock-work, bearing a profusion of pink-like fls. The fls. sometimes vary to white (*Fénzlia álba,* Hort.). A large-fld. form is called *G. speciòsa.*

AA. *Plants shrubby.*

18. **califórnica,** Benth. A low, procumbent and much-branched shrub: lvs. alternate, deeply digitately parted into 5–7 stiff and hairy segms: fls. showy, very free; sepals subulate, mucronate; petals cuneate, sometimes toothed, rose-colored. Calif. B.M. 4872.—A fine showy species, perhaps not hardy in the E.

G. abrotanifòlia, Nutt., occurs in mountains back of Santa Barbara, and has been listed in collections of native plants for sale: 1–2 ft., simple or somewhat branched: lvs. ample, all tripinnately dissected, the ultimate segms. very narrow and acute and curved backward: fl. without markings (blue?), large, the lobes spreading, obovate and obtuse; stamens scarcely protruding.—*G. Chamissònis,* Greene, is a segregate from G. achillæfolia: annual, but sometimes persisting over winter, 1 ft.: lvs. mostly twice pinnately dissected into linear segms.: branches few and peduncle-like, bearing large and dense heads of blue fls. Calif.

N. Taylor.†

GILIBÉRTIA (J. E. Gilibert, 1741–1814, France, physician and botanist). *Araliàceæ.* A genus of very few Trop. American shrubs (if Dendropanax is separated) that are not known in cult. The name is one frequently but incorrectly used by gardeners for Trevesia, and *G. palmata* is described under that genus. *G. paniculata* and one or two others are referred to Polyscias. Gilibertia differs from Trevesia in having parts of the fl. in 6–8's instead of 8–12's, and in its simple entire lvs. From Dendropanax it differs mostly in its 6–8-merous rather than 5-merous fls. N. Taylor.

GILLÈNIA (dedicated to an obscure German botanist or physician of the seventeenth century, A. Gille or Gillenius). Syn. *Porteránthus. Rosàceæ.* Excellent graceful plants for the mixed border, rockeries, or other hardy gardens.

Erect, perennial herbs, 2–4 ft. high, with nearly sessile, 3-foliate, or 3-parted, stipulate lvs.: fls. white or pinkish, loosely panicled, perfect, perigynous; cup-shaped receptacle narrow, somewhat contracted at the mouth, 5-toothed; petals strap-shaped, unequal, 4–8 lines long; stamens 10–20, very short; pistils 5, superior, lightly coherent, later distinct, pubescent: fr. consisting of 5 2–4-seeded follicles.—Two species. They are hardy and of easy cult. in any good soil. Prop. by seeds or division.

trifoliàta, Moench. Bowman's Root. Lfts. serrate; stipules small, awl-shaped, mainly entire. Cent. and S. U. S. B.M. 489 (as Spiræa). Mn. 8:129. J.H. III. 43:188.

1640. Ginkgo biloba.

stipulàta, Trel. (*G. stipulàcea*, Nutt.). American Ipecac. Lfts. incised; stipules large, broad, and leaf-like, doubly incised. Cent. and S. U. S.

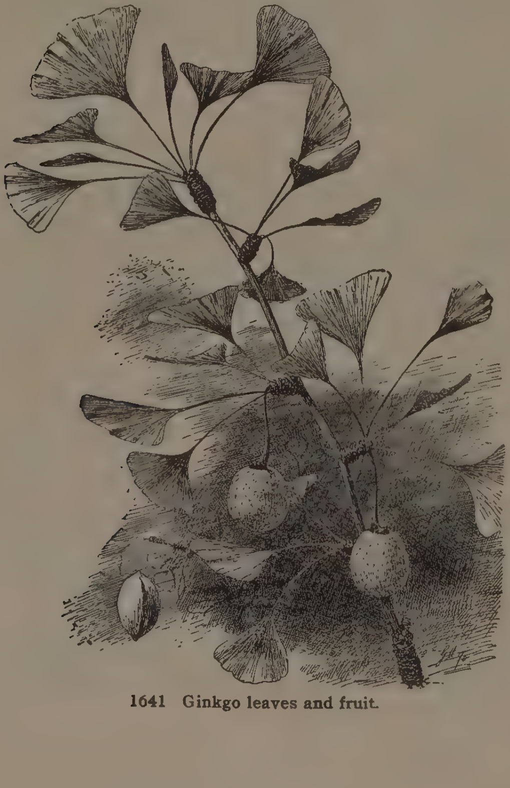
K. M. Wiegand.

GILLYFLOWER. Down to Shakespeare's time usually referred to what we now call the carnation, *Dianthus Caryophyllus*, also known as clove pink. Since Shakespeare's time gilliflower has usually meant either wall-flowers or stocks, as explained under Cheiranthus and Matthiola.

GINGER: *Zingiber officinale.* **Wild Ginger:** *Asarum canadense.*

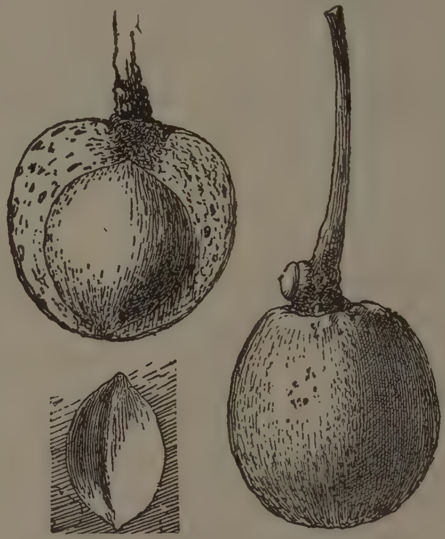
GÍNKGO (Chinese name). Syn., *Salisbùria. Ginkgoàceæ*, one of the segregates from the *Coniferæ*. One species in northern China and Japan, the sole remainder of a more numerous tribe in geologic time; now widespread as a street and park tree and also prized for the edible seeds.

Tall tree, with wedge-shaped deciduous lvs.: fls. small and mostly diœcious; pistillate fl. solitary, the single naked ovule ripening into a drupe; staminate fls. in slender, loose catkins: fr. a drupe about 1 in. diam., containing a very large lenticular seed or kernel.



1641 Ginkgo leaves and fruit.

bìloba, Linn. (*Salisbùria adiantifòlia*, Smith). Ginkgo. Maidenhair Tree. Kew Tree. Figs. 1640–1642. A straight, sparsely branched, usually slender tree, attaining a height of 60–80 ft.: lvs. 3–5, 1-clustered, fan-shaped, divided at summit, with thickened margin, striated on both sides with numerous parallel veins: fls. diœcious; male catkins slender, stalked; females on long footstalks, in pairs, of which one usually aborts: fr. a drupe, consisting of an acrid, foul-smelling pulp surrounding a smooth, angular oval, cream-colored, thin-shelled, sweet-kerneled nut. F.S. 10, p. 119. G.C. III. 5:265, 269. G.F. 1:175 (adapted in Fig. 1640). A.G. 12:268. Gng. 6:194. G.M. 52:1011. Gn. 66, p. 345. Gn.M. 2:11. G.W. 3, p. 542; 10, p. 285; 15, pp. 589–593. J.H. III. 64:148.—The ginkgo was intro. to Amer. early in the last century; it is generally successful on good soil in the eastern states as far north as E. Mass. and Cent. Mich., and along the St. Lawrence River in parts of Canada. It is of special value for solitary planting to secure picturesque effects. It is considerably planted in Washington, D. C., where it is growing in esteem as a street tree because of its upright habit and freedom from insect injury. Easily prop. from seed, stratified in autumn; varieties by budding and grafting. Several horticultural forms are recognized, including *laciniata*, *pendula* and *variegata*. The foul odor of the ripe frs., which continue to mature and drop during a period of some weeks, constitutes the chief objection to the species as a street tree, or near dwellings, and suggests the advisability of prop. from staminate trees by grafting or budding, for planting in such locations. The kernels, which have a sweetish, slightly resinous flavor, are highly esteemed for food in China and Japan, and are gathered from fruiting trees in Washington for such use by Chinese laundrymen.

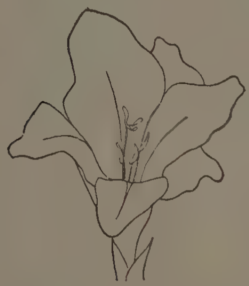


1642. Ginkgo fruit. (Natural size)

The word Ginkgo seems to be pronounced with a hard initial G in the orient, but in English a soft G should be used. The name is often spelled Gingko, but the other spelling is that used by Linnæus.

W. A. Taylor.

GINSENG (*Pànax quinquefòlium*, Linn. *P. Gínseng*, Meyer. *Aràlia quinquefòlia*, Decne. & Planch.) is to the Chinese more than quinine or any other drug is to Americans. As its name Panax implies, it is a panacea, being employed for all the ills that flesh is heir to. Though credited with stimulating, aromatic, alterative, carminative and tonic properties, the root is with us seldom used except as a demulcent. The reverence in which it is held, and the high price that it commands in China, led to extensive search for a substitute, which resulted in the discovery in 1716 of American ginseng, *Panax quinquefolium*, near Montreal, Canada. This root was favorably received by the Chinese, and soon became an important article of export. During the past fifty years the price of American ginseng has advanced nearly 700 per cent, but owing to the energetic hunt for the root, to the destruction of forests and to the gathering of plants at improper times, the wild supply has greatly decreased. With the advancing prices and the diminishing supply came experiments in ginseng cultivation, most of which failed through ignorance of the plant's peculiarities. The seed ripens in September. If dry it will not germinate until the second year, but if fresh and properly kept nearly all the seeds will germinate the first season. The soil must be a light, friable loam, free from stones, rich in humus and well drained; the plants must be well supplied with shade and moisture. Cultivated ginseng already commands a considerably higher price than the wild root, and, though no returns can be expected from a plantation under three or four years, the industry is profitable to the men that have given it careful attention.



1643. Parts of a gladiolus flower. Showing the three stigmas, three stamens, six segments of the perianth, and the tips of the spathe-valves.

Ginseng beds can be located in orchards, gardens, or woods, where the roots may remain without danger of deterioration for several years after they first attain marketable size. The roots are so valuable that they are likely to be stolen, and beds should, therefore, be placed where they can be guarded.

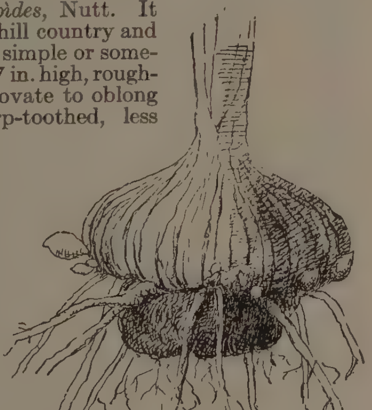
For further information on ginseng, send to Division of Publications, Department of Agriculture, Washington, D. C., for Bulletin No. 16 of the Division of Botany, revised by M. G. Kains in 1898, or consult Kains' Ginseng, its culture, etc., Orange Judd Company 1899; second edition, 1902. For diseases, consult Cornell bulletins.

M. G. Kains.

GITHÀGO: *Lychnis.*

GITHÓPSIS (*like Githago*, from the calyx). *Campanulàceæ.* One blue-fld. annual in Calif., sometimes recorded in horticultural literature, *G. specularioìdes*, Nutt. It grows in the open hill country and the mountains: st. simple or somewhat branched, 4–7 in. high, rough-pubescent: lvs. obovate to oblong or narrower, sharp-toothed, less than ½in. long: corolla tubular-bell-shaped, the lobes shorter than the tube; calyx 10-ribbed, adnate to the ovary: fr. a coriaceous caps., bearing the rigid calyx-lobes, dehiscing at apex. Var. *diffùsa*, Jepson, is nearly glabrous, but sinuses of calyx somewhat hispid.

L. H. B.



1644. Gladiolus corm growing above the old one; and the cormels from the bottom.

GLADÌOLUS (diminutive of Latin *gladius* a sword, from the shape of the leaves). *Iridàceæ.* Popular summer-flowering and autumn-flowering bulbs, and now somewhat grown under glass.

Corm-bearing herbs with fls. in simple or branched spikes; lvs. radical and cauline: fl. more or less tubular, the tube usually funnel-shaped (enlarging upward); segms. 6, more or less unequal, strongly narrowed or even clawed at the base, the upper ones often hooded or roofed over the opening or mouth of the fl.; stamens 3, inserted on the tube; stigmas 3, on a long style; ovary 3-loculed, becoming an oblong 3-valved caps., with flattened and winged or sometimes globose seeds: each fl. is borne in a sessile spathe (like a calyx) with linear or lanceolate valves or lf.-like parts: the lvs. are mostly equitant on the st., all firm and prominently several-ribbed, varying from linear to sword-shaped (sometimes almost terete): the old corm dies and a new one grows on top, and cormels or offsets (sometimes called "spawn") form from the underpart (Fig. 1644).—The species of Gladiolus are 160 or more, perhaps 100 being in S. Afr. (Cape), many in Trop. Afr. in both the E. and the W., and others in the Medit. and W. Asian regions. The greater part of highly improved garden forms are derived more or less directly from the S. African species. The Eurasian species are little grown, although some of them are hardy. Gladioli have been much modified by variation, hybridizing and selection.

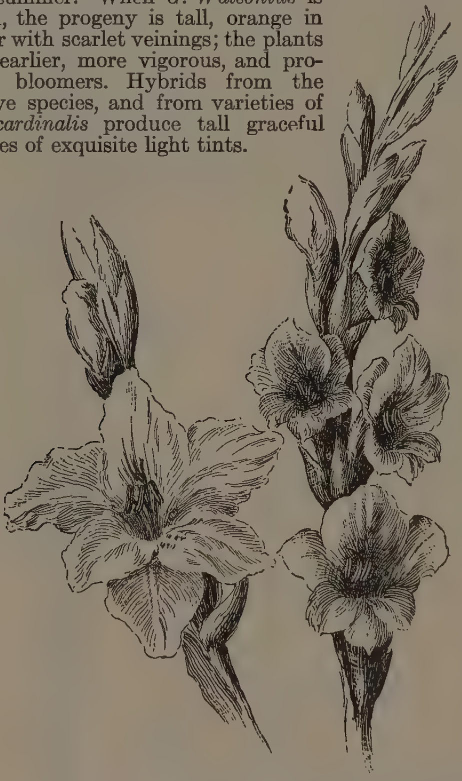
The gladiolus is propagated readily by seeds, as explained farther on; by the use of the new corm growing above the old one, and which is separated either when cleaning in autumn or before planting in spring; by the young corms, or cormels. Increasing stock by the small corms or cormels is the most common method, and the one by which a variety is perpetuated. The small corms are stored in bags, boxes or other suitable receptacles and kept from frost. It is a help to sprouting if the cormels are not allowed to dry out during the period of rest. They should be planted like one-year seedlings, and they give blooming plants the first and second year.

Great progress has been made in recent years in the improvement of the gladiolus, until in floriferousness, form, color, substance and keeping qualities it has become one of the important summer flowers, both for amateurs and florists. It is to be expected, however, that many other forms and qualities are yet to appear, considering the great number of wild species of much beauty that have not been combined in the cultivated strains. It may be possible, also, that closely related genera can be used to some extent in hybridizing. The lines of division between Gladiolus, Antholyza, Acidanthera, and some others, are more or less arbitrary.

1645. Gladiolus gandavensis. (×⅓)

The early departures were of the gandavensis (Fig. 1645) and similar types, founded probably on *G.*

psittacinus and *G. cardinalis.* Forms of *G. tristis* early entered into the cultivated strains, as well as *G. oppositiflorus,* and later *G. purpureo-auratus* and *G. Saundersii.* The Lemoinei and nanceianus races (Fig. 1646) have afforded foundations for much subsequent breeding. Recently, *G. primulinus* has entered into the combinations. It seems to be particularly valuable as a parent; it is said to be dominant in color over even the deepest reds, subduing them to excellent shades of orange, salmon, and terra-cotta; when crossed with the lighter colors it transforms them to buff, lemon and ecru; combined with yellow the color is deepened. The hooded character is commonly inherited. W. W. Van Fleet has succeeded in crossing this species with many of the other wild forms. With *G. Quartinianus* the color is said to be toned down to terra-cotta and the season for blooming is changed from autumn to midsummer. When *G. Watsonius* is used, the progeny is tall, orange in color with scarlet veinings; the plants are earlier, more vigorous, and profuse bloomers. Hybrids from the above species, and from varieties of *G. cardinalis* produce tall graceful spikes of exquisite light tints.



1646. Gladiolus Lemoinei (on the right), and G. nanceianus. (× ⅓)

The ruffled strains of gladioli have appeared in recent years, adding a pleasing variety and much merit to the flower. This type has been specially developed in the recent breeding work of A. E. Kunderd, of Goshen, Indiana (Fig. 1647). Nearly twenty years ago he began his selections for the production of a frilled or wavy flower, that should have something of the petal-edge exhibited so well in azalea. Early- and late-flowering strains have been produced. It is said that one strain has the blood of *G. Quartinianus* and is producing many good shades of red with fluted or ruffled petals and suitable for late-flowering purposes. *G. primulinus* has also given good tints in yellows, with flowers very much frilled. It now seems possible to introduce the ruffling into many of the standard types, much as has been done with the sweet pea.

The recent Burbank strains have been developed from the variety America as the seed-parent. These are said to comprise many very large-flowered forms, with brilliant coloring.

The *G. præcox* group or strain was introduced by Frederick Roemer, of Quedlinburgh, Germany, said to be the result of intercrossing the earliest-flowering plants of *G. gandavensis, G. Lemoinei, G. Childsii* and *G. nanceianus.* In color, markings, or size, the race compares favorably with the parents, and at the same time the plants bloom the first year from seed, especially when the seed is started in a moderate hotbed in March. As growth advances, they are given ventilation gradually. There is a decided improvement the second year, when two or more spikes of normal size are usually produced. Other strains of gladiolus may also give bloom the first year from seed.

Some of the earlier history of American gladiolus-breeding was written for the "Cyclopedia of American Horticulture" by H. H. Groff, of Canada, one of the prominent contributors to the improvement of the flower (extracts): Some twenty-five years ago "when the writer, under the inspiration of Luther Burbank, began his own work in hybridization, the best American-grown stock available was the Hallock collection of some 400 named varieties of gandavensis and about 100 of the earlier Lemoine hybrids, all of European origin. After trial, the writer placed them all in mixtures. About this time Luther Burbank began to offer a few named varieties, but shortly afterward sold his whole stock, the collection being now in the writer's hands. This collection, in the opinion of the writer, is the best strain of gandavensis. The varieties were largely of variegated types, with many of unique markings and peculiar form. Burbank had given particular attention to varieties calculated to withstand the hot, dry winds of California, and had originated several with specially stiff petals, quite distinct from the ordinary types. The peculiarity of the flowers blooming around the spike like the hyacinth was also his contribution. All of his varieties are now grown in mixture by the writer with the exception of a white variety, which promises to be distinct and valuable for some time to come. The work of Van Fleet, of New Jersey, was carried on more for scientific than commercial results, and reaped a deserved success. However, the writer has found that the offspring of a pure species is less stable than that of well-balanced cross-bred varieties, the former system handing down few varieties of permanent commercial value, though they are in themselves valuable as parents for the foundation of new strains. The best work of a semi-professional character, in the opinion of the writer, has been done by T. S. Moore, of Indiana, who has spared no trouble or expense in procuring choice material upon which to build, and with satisfactory results." Writing in 1914, Groff speaks of the fluted, ruffled and crimped forms being frequent in the progeny of every improved species; of the development of iris-form flowers; and of innumerable influences, under breeding, on the character of the stalk, fiber, capsule, shape and size of foliage, disposition of flowers to droop or to grow erect, on the corm and its husk and the facility of producing cormels, and other interesting departures.

The interest in the gladiolus has been much stimulated in North America by the work of the American Gladiolus Society. It was organized at Boston, May 27, 1910, for the purpose of "stimulating interest in, and promoting the culture and development of the gladiolus; to establish a standard nomenclature; to test out new varieties, and to give them such recognition as they deserve; to study the diseases of the gladiolus, and find remedies for same; to disseminate information relating to this flower; to secure uniformity in awarding prizes at flower shows, and to give one exhibition each year." The society holds exhibitions, publishes a bulletin, and in many ways aids in the popularizing of the gladiolus and in establishing standards of excellence. It has a trial-ground at the New York

State College of Agriculture at Cornell University, where gladioli are now being carefully studied.

Following is a score-card prepared by direction of Gladiolus Society of Ohio:

	Points
1. Spike (long, 5; straight, 5; many blooms, 5; facing together, 5)	20
2. Flower (large, 5; widely opened, 5; broad, round petals, 5; substance and texture, 5; beauty of bud, 5)	25
3. Color (attractive, 10; either self-color, or strikingly marked, 5; adapted to cut-flower trade or florists' use, 5)	20
4. Foliage (dark, healthy green, 5; broad, 5; abundant, 5)	15
5. Durability (continuance of bloom on spike, 5; lasting qualities as cut-flower, 5)	10
6. General effect (in mass bed or field, 5; in vase or cut display, 5)	10
Total	100

Culture of the gladiolus. (Isaac S. Hendrickson, except when otherwise stated.)

The Gladiolus has several good points combined to make it interesting, popular, and promising, as: The low cost; ease of culture; freedom from insects; variation in color; ease of carrying over from year to year; length of blooming season; rapid increase; ease with which new varieties are produced.

Figures recently compiled from information given by the growers in the United States are as follows:

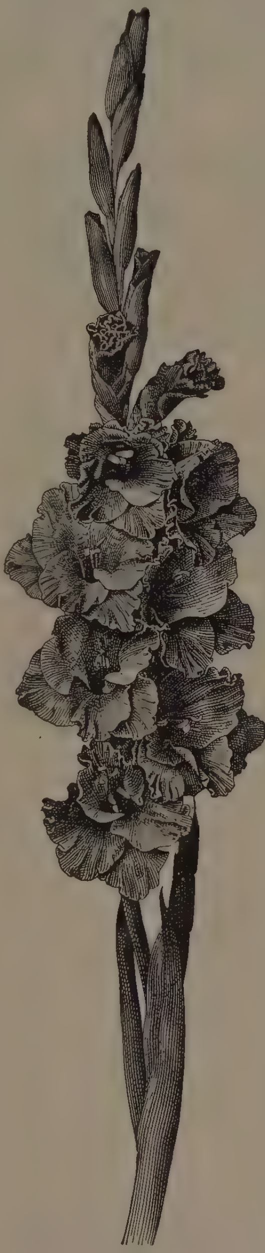
Number of acres devoted to gladioli	400 to 500.
Estimated number of bulbs produced annually	14,000,000 to 15,000,000
Estimated value of crop	$250,000

Raising new varieties.

It is the contention of some growers that certain definite results can be secured by hand-crossing of different varieties, while other growers assert that they cannot trace a single valuable result to that method. The writer's observation has led him to the opinion that some of the best and most useful sorts on the market today are the results of careful selection of seed from the varieties showing best form, growth, color, vigor, size, and other qualities. It is well for the general gardener to purchase a collection of the best-named kinds now on sale, plant them together and let the insects transfer the pollen naturally; and if the weather is favorable, one is almost sure to have a crop of seed. This seed must be carried over until the following spring, when it can be planted in shallow drills, covering about one-eighth to one-fourth inch with soil; they will make only a slight grass-like growth the first year, and must be taken up in the fall, and housed away from frost. The following spring they can be planted as one would sow garden peas, and covered about 1½ inches deep; they will make a little more growth and perhaps a small percentage will flower, but the bulbs will have to be lifted and planted once more before a good showing of flowers can be expected. The commercial grower expects to wait three or four years after planting the seed before he has salable bulbs, which of course, can be sold only as seedlings or mixtures as all forms and colors will be present. In looking for new varieties to name, the greatest care must be taken to choose only those of real merit, something that is distinct from previous selections, new in color, good in substance, excellent in form, and in all ways meritorious. When the selection is finally made from perhaps thousands of seedlings, it is labeled out and lifted separately in the fall, and jealously guarded until the next planting-time; then it is watched with eagerness to see whether it will prove constant and worth taking the trouble to "bring up," for as it requires at least ten years to secure enough bulbs to offer for sale, one can easily waste much time if the selection does not prove to be a wise one. It is often said that there are too many varieties now under name, and this is true; but as it is so very easy and so fascinating to grow seedlings, one should not discourage the amateur in securing this satisfaction.

Of course the professional or expert breeder will exercise the most careful choice of the parent stocks; and he is able to make many interesting and valuable combinations of special qualities.

Culture.



1647. The ruffled gladiolus. (×¼)

While nearly any good garden soil is adapted to the culture of the gladiolus, the plant seems partial to a sandy loam. In field culture, gladioli are usually planted in rows similar to potatoes; that is to say, the furrows are made 3 feet apart to allow tillage with horse. The bulbs are placed in the row by hand, usually about 2 to 4 inches apart each way according to size, and covered about 4 or 5 inches deep. Deep planting prevents them blowing over. Frequent tillage must be given in spring and summer.

For garden culture, they may be planted promiscuously in the border if wanted for garden decoration; or if wanted for cut-flowers principally, the straight-row method is best, as it enables better tillage to be given and makes it much easier to cut the blooms. The gladiolus is essentially a cut-flower. If one has a goodly number of bulbs, it is an excellent plan to make successive plantings about fifteen days apart, beginning as early as the ground can be worked and continued until July. This will insure continuous bloom from July until October, or until the plants are cut down by frost. As the old bulb or corm produces its flower, it dies and a new one forms in its place, and develops until harvest time, when it is lifted and stored in a warm dry place; some time during the winter the roots and old bulb should be taken off, so that the bulb will present a clean appearance and be ready for planting.

As a cut-flower, the gladiolus will rival most other flowers in keeping qualities. The blooms can be kept fresh and beautiful for a period of five to ten days after cutting by changing the water daily and removing each day the withered blooms; it also helps if the ends of the spike are nipped off when changing the water. If the spikes are cut when the first two or three flowers have opened, the entire stalk will open out after it has been put in water. They may be sent to a distance; they will arrive in excellent condition if a little care is taken when shipping. The spikes should be cut when the first flower opens, and put in water in the cellar or cool place for two or three hours, after which they will stand a journey of two or three days; and then when placed in water they will quickly respond and unfold their petals.

The uses of gladioli are varied; great quantities are used for decorating dining tables in the great hotels and steamboats; florists have long recognized their value in making funeral designs; at the exhibition of the American Gladiolus Society, at Rochester, it was demonstrated that they can be used for fancy table decoration, wedding bouquets, and other purposes.

Varieties.

No two persons will agree on varieties, but the following represent some of the good types at present (given here as a matter of record):

White.—Europa, Blanche, Peace, LaLuna. *Pink.*—Wild Rose, America, Mrs. Frank Pendleton, Myrtle, Taconic, Panama. *Scarlet.*—Mrs. Francis King, Princeps, Brenchleyensis, Contrast (scarlet and white). *Yellow.*—Golden King, Sulphur King, Niagara, Kunderdi Glory. *Maroon.*—Empress of India, Mrs. Millins. *Violet.*—Baron Joseph Hulot.

Variation in size of bulbs.

There is great variation in size of bulb or corm. It is a varietal characteristic. Some kinds never make a large bulb, yet they may be superior kinds. This ought to give a hint in buying mixtures at the flower-shop. Nine times out of ten, when a customer has the opportunity to pick out the bulbs personally, the very largest ones are taken, with the result that perhaps not more than one or two kinds are received, as very often the very best and choicest flowers are concealed in the small or medium-sized corms. Some of the large-bulb sorts are very inferior, and it is easy to increase the stock, while others, perhaps producing smaller bottoms, bear only a few offsets.

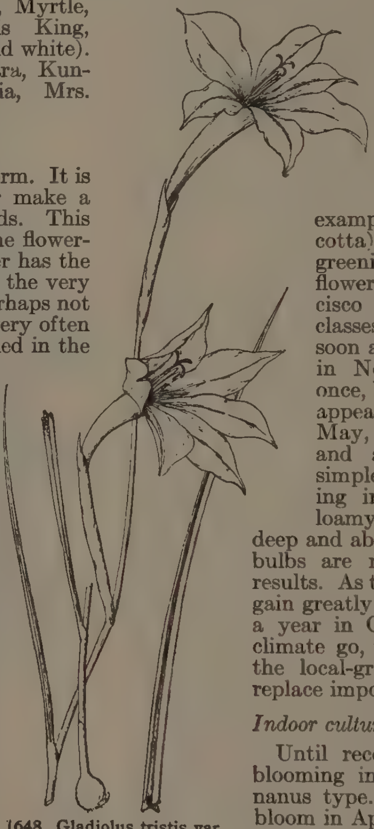
Commercial cultivation for stock or bulbs.

(E. H. Cushman.)

For successful commercial culture it is essential that sandy soil conditions are obtainable. Such preparation of the soil as puts it in a loose, friable condition will answer. Probably the ideal soil is a sod, fall-plowed and then most thoroughly worked in the spring. Strong, fresh stable manure should be avoided. If soil is not sufficiently rich in plant-food it is best to use all strong manures on a previous season's crop of some other kind. Any complete fertilizer is beneficial when thoroughly worked through the soil, at the rate of 600 to 1,000 pounds to the acre. Planting should be begun as early in the spring as the proper working of the soil will permit. The ground being prepared, it should be furrowed 4 inches deep and from 24 to 36 inches apart, according to method of cultivation. If fine, round bulbs are to be grown, and the stock for planting exceeds 1½ inches in diameter, it will be necessary to place the bulbs right side up in the furrow by hand, either in single or double rows 2 inches apart. Bulbs of lesser size may be scattered as evenly as possible along the furrow, with an average of ten or twelve to the foot of furrow. Clean culture throughout the growing season is essential. Cutting the spike of flowers is a help to increasing the size of the bulbs. Four months is sufficient for the growth and maturity of the bulb. To harvest, loosen the soil and lift the bulbs by their tops, and lay on the ground to dry off and ripen. Should weather permit, they can be entirely ripened out-of-doors Cut the tops off close to the bulbs, pulling off the old bulbs and roots, and place in thin layers in crates and store in a cool, dry place. If circumstances require, the tops may be trimmed off at once on lifting, and the bulbs taken under cover for cleaning and drying.

Culture in California. (Sydney B. Mitchell.)

Gladioli, like all South African bulbs, do very well in California; indeed near Santa Cruz, some of the popular large-flowering varieties are grown in commercial quantities for their bulbs. These summer-flowering kinds may be planted in the fall to bloom in the following May and June, but in private gardens additional corms should be put in at intervals from April to July so that a succession of flowers may be available until October, right through the season when California gardens are barest. It should be noted that the early-flowering class of the nanus and Colvillei types are also quite hardy here and so do not require the glass protection given in the East. The favorite varieties of the nanus or dwarfs are Peach Blossom and Blushing Bride, while The Bride easily leads in the Colvillei section. A few of the less-known early species are also grown occasionally, as for example *G. tristis* (yellow and terra-cotta) and its variety *concolor* (pale greenish yellow), both of which flower in March around San Francisco Bay. The earlier-flowering classes should all be planted just as soon as available in late October or in November. Growth starts at once, but the flowers usually do not appear much before the following May, when they make a brave show and are fine for cutting. Their simple requirements are fall-planting in a well-drained, preferably loamy soil, put about 3 inches deep and about the same apart. Separate bulbs are reset each autumn for best results. As they increase quite rapidly and gain greatly in vigor after they have had a year in California, as far as soil and climate go, there is no good reason why the local-grown bulbs should not quite replace imported ones.



1648. Gladiolus tristis var. concolor. (×½)

Indoor culture. (A. C. Hottes.)

Until recently, the gladiolus used for blooming indoors was principally of the nanus type. Planted in November, they bloom in April and May. They may first be started in 5-inch pots and later benched. They require a cool temperature, about 45° at night, if one expects the foliage to develop nicely. This is a temperature near that of the carnation optimum; they are therefore, often planted around the margins of the carnation benches. Their growth at first is slow, making little growth till the sun gets higher in the spring.

The flowers of the nanus type appear two or three weeks earlier than the standard varieties of gandavensis, Lemoinei or nanceianus. Varieties of the latter groups, however, are being developed with the desirable qualities for forcing, that of earliness and of a pleasing commercial color, and are becoming of considerable importance as a spring flower for the florist.

If the stems are not cut too short, the corms will renew themselves as well as in outdoor culture and they can be forced again or given a year's growth in the field.

XLVIII. The garden gladiolus, variety "Peace."

The kinds of gladiolus.

The following account includes those species that appear to have any particular horticultural history; also some of the prominent Latin-named hybrids, although not all these hybrids may now be in commerce.

I. SPECIES OF GLADIOLUS (NOS. 1–27).

Few of the original species of Gladiolus are in cultivation in their pure form. When grown at all, they are prized chiefly as oddities, or because of their botanical interest. The following species are either offered at the present time in the trade or are parents of modern garden forms:

A. *Fl. with a long, slender, cylindrical curved tube, which is enlarged in the middle; segms. nearly equal. (Homoglossum.)*

1. **Watsònius,** Thunb. (*Antholyza revolùta,* Burm.). Corm 1 in. diam., globose: st. slender, 18 in. or less, with 1 long, narrow-linear and stiff lf. and 2–3 short sheathing lvs.: fls. 2–4, in a lax 1-sided spike, 2 in. or less long, bright red, the wide-spreading segms. oblong and acute, the lower ones smaller and lanceolate-falcate; stamens very short. S. Afr. B.M. 450.—Little known in this country, but offered by Dutch growers.

AA. *Fl. short and open, the tube short or scarcely any; segms. very prominently clawed, usually unequal.*

2. **alàtus,** Linn. Corm small, globose: small, the st. only 4–12 in. high, and slender: lvs. 3–4, linear and rigid: fls. 3–4 in a lax spike, the curved tube ½in. long, the perianth pink and often strongly veined; segms. very unequal, the 3 lower tongue-like and protruded, the others obovate or nearly orbicular, all of them differently colored toward the base; stamens nearly as long as upper segms. S. Afr. B.M. 586; 592; the var. **namaquénsis,** Baker, which is more robust, with broader lvs., more fls., the upper segms. broad.

AAA. *Fls. of medium length, with a funnel-shaped tube, which is flaring at the top; segms. narrowed below, but not distinctly clawed. (Gladiolus proper.)*

B. *Lvs. linear (½in. or less wide).*

C. *Perianth-segms. acute.*

3. **grándis,** Thunb. (*G. versícolor,* Andr.). Corm globose, with coverings of thick wiry fibers: st. slender, 2 ft. or less, terete: lvs. about 3, terete, strongly ribbed, 1½ ft. or less long: fls. 6 or less in a lax 1-sided spike, 3 in. long, with a curved tube; segms. nearly equal, oblong-lanceolate and cuspidate, as long as the tube and twice longer than the stamens, recurved and often wavy, yellowish or creamy, tinged and striped with purple-brown, especially on the keel: caps. oblong, 1½ in. long; seeds winged. S. Afr. B.M. 1042.

4. **trístis,** Linn. Very like the last: fls. 2–4, somewhat smaller (2 in. or less long); segms. shorter than the tube and not twice longer than the stamens, acute (short-pointed), yellowish white with purple or blackish pencilings, or var. **cóncolor,** Hort., Fig. 1648 (*G. cóncolor,* Salisb.), almost white or uniform yellow. S. Afr. B.M. 272, 1098. G. 21:649. Gn. 75, p. 420. G.C. III. 38:187 (var. *concolor*). G.F. 8:75 (reproduced in Fig. 1648).—Said to exhale a powerful and delightful lemon perfume at night.

5. **angústus,** Linn. (*G. trimaculàtus,* Lam. *G. cordàtus,* Thunb.). Corm globose: slender: st. 2–3 ft., simple: lvs. 3–4, very narrow, flat, 2 ft. or less long: fls. 2–6 in a very loose spike, long-tubed, white, the oblong segms. shorter than the tube and the 3 lower ones with a characteristic purple median line ending in a heart-shaped or spade-shaped mark; stamens half length of limb. S. Afr. B.M. 602.

CC. *Perianth-segms. obtuse.*

D. *Color purple or violet.*

6. **crispiflòrus,** Herb. (*G. imbricàtus,* Linn., var. *crispiflòrus,* Baker). St. 1–2 ft., rather slender: lvs. 2–3, sometimes ½in. broad: fls. 4–10, the tube ¼in. long and curved, the segms. obovate (1 in. long), crisped or wavy on the edge, dark purple, more or less marked with white and red: seeds winged. E. Eu. and W. Asia.—Hardy or nearly so.

7. **atroviolàceus,** Boiss. Corm ovoid, ¾in. or less diam.: st. 1–2 ft. high: lvs. 3, closely ribbed, firm: fls. few, the tube ⅓in. long and curved, the obovate segms. 1 in. long and dark purple or violet-blue: seeds globose, not winged. W. Asia. G.C. III. 41:378.—Hardy or nearly so.

8. **biflòrus,** Klatt. Corm globose, small (½in. diam.): dwarf (1 ft. or less), the st. slender and terete and bearing only 1 well-formed lf., which is subterete and very narrow and 5–6 in. long, the 2 upper lvs. rudimentary: fls. 2–3, lilac, the tube nearly straight, the oblong segms. twice as long as the tube; stamens reaching half-way the limb. S. Afr.—Connects with Geissorhiza.

DD. *Color (under-color) white or nearly so.*

9. **vittàtus,** Hornem. (*G. vínulus,* Klatt. *G. fasciàtus,* Roem. & Schult. *G. undulàtus,* Schneev.). Corm globose: plant low (about 1 ft.): lvs. 3–4, very narrow: fls. 3–6 in a lax spike, nearly erect, the slightly curved tube nearly or quite an inch long, the limb longer than the tube, pink, the 3 lower segms. with a purple central blotch; stamens reaching half-way the limb. S. Afr. B.M. 538 (as *G. undulatus,* var.)

BB. *Lvs. ensiform (½in. or more broad, and flat or flattish).*

C. *Under- or body-color essentially purple.*

10. **commùnis,** Linn. Corm about ¾in. diam.: st. 1½–2½ ft.: lvs. 3–4, 1 ft. or less long: fls. 4–8, small (1½ in. long), with a curved tube; segms. bright purple (flesh-colored in the var. *carneus*), nearly equal in length, all connivent or touching (making a narrow fl.), the 3 lower ones long-clawed and with a median line: seeds broad-winged. France, Germany. B.M. 86, 1575.—Hardy; little known in cult. in this country. Variable; Nos. 11 and 12 are by some considered to be forms of it.

11. **byzantìnus,** Mill. Fls. more and larger, plant more robust than in No. 10, segms. more spreading at maturity, although the 3 upper ones are contiguous, dark purple, the 3 lower ones with a prominent white median line: seeds winged. Medit. region. B.M. 874.—Hardy; little known in gardens.

12. **ségetum,** Ker. Differs from *G. byzantinus* in having globular (not winged) seeds, and in the flaring or spreading segms. of the bright purple, obovate-obtuse sepals. Canaries and Medit. region. B.M. 719.—Hardy and early; little grown.

13. **Papílio,** Hook. f. Corm of medium size, globose: st. 2 ft. or more: lvs. about 4, rigid, 1 ft. or more long and 1 in. or less wide: fls. 6–12, pale purple or lilac, yellow in the throat; perianth horizontal, the curved tube ¼in. long and broadly funnel-shaped at the top; 3 upper segms. obovate-spatulate, uppermost not reflexing, ½–¾in. broad, 1½ in. long, the lower ones very narrow below and marked with large red-brown spade-shaped yellow-edged blotches. S. Afr., in the Transvaal, Orange Free State and Natal. B.M. 5565.—Handsome. Varies to white in cult.

cc. *Under- or body-color essentially red* (*No. 22 may be sought here*).

14. **Leìchtlinii,** Baker. Corm large and globose: st. about 2 ft. tall, terete: lvs. about 4, ensiform, 1 ft. long: fls. 6–8, large, in a somewhat dense 1-sided spike, bright red, with a curved tube 1¼ in. long; upper segms. obovate and connivent, equaling the tube, 3 lower ones much smaller and acute, spreading, red at tip but yellow and minutely red-dotted below; stamens shorter than upper segms. Transvaal.

15. **cardinàlis,** Curt. Corm large and globose: st. 3–4 ft.: lvs. 4–6, glaucous-green, ensiform, nearly or quite 1 in. broad and reaching 2 ft. or more in length: fls. many (sometimes 20), nearly erect, bright scarlet, the tube 1½ in. long and nearly straight; upper segms. oblong-spatulate (2 in. long), scarlet, the 3 lower ones shorter and narrower, with a large white blotch; stamens more than half the length of the limb. S. Afr. B.M. 135.

1649. Gladiolus purpureo-auratus. (×⅝)

16. **cruéntus,** Moore. Corm large, globose: st. 2–3 ft.: lvs. about 4, ensiform, dark glaucous-green, 2 ft. or less long, ¾–1 in. broad: fls. 6–10 in a rather dense distichous spike, bright scarlet; tube 2 in. or less long, nearly straight; upper segms. obovate-spatulate, to 2½ in. long; 3 lower segms. 1½ in. long, white-blotched and red-spotted; stamens reaching half-way of limb. Natal. B.M. 5810.—Closely related to No. 15.

17. **Saùndersii,** Hook. f. Corm large, flattened-globose: height 2–3 ft.: lvs. 4–6, strongly ribbed and stiff, 1–2 ft. long and 1 in. or less broad: fls. 6–8, large, bright scarlet, the tube 1–1½ in. long and curved; 3 upper segms. oblong-spatulate, uniform scarlet, connivent (2 in. long), 3 lower smaller, white-blotched and scarlet-spotted. S. Afr., coast region to Transvaal. B.M. 5873. Gn. 12:64.—Handsome. Var. **supérbus,** Hort., is a form produced by the early infusion of *G. Saundersii* into the garden strains.

18. **Quartiniànus,** Rich. Corm to 1½ in. diam., globose: strong, 2–4 ft.: lvs. 3–4, rigid, sometimes nearly ensiform, the lower ones 1½ ft. or less long, and ¾in. or less broad: fls. 4–9, in an open spike, large, blood-red. the narrow curved tube 1½ in. long; upper segms hooded, the other smaller and more or less reflexed; stamens nearly equaling upper segms. Nile Land to Lower Guinea and Mozambique. B.M. 6739. G.C. III. 24:467, and Gn. 55:388 (var. *superbus*). Trop. Afr.—One of the best of the genus. Named for M. Quartin Dillon, who discovered it in Abyssinia.

ccc. *Under- or body-color at least, yellow.*

19. **primúlinus,** Baker. Very like No. 18 (with which Baker subsequently united it), but differs in the yellow color: corm globose, 1 in. and more diam.: lvs. about 3, ensiform, 1½ ft. long and to 1 in. broad: fls. 3–5, in a lax secund spike, clear primrose-yellow throughout; tube 1 in. long, much curved above; 3 upper segms. ovate or obovate, acuminate, hooded, 2 in. long and more than 1 in. wide, the central one covering the stamens and stigmas; 3 lower segms. deflexed and much smaller; style exceeding the stamens. Trop. Afr., occurring in the rain-forests. B.M. 8080. G.C. III. 36:191; 42:291. R.H. 1908, p. 9.—A handsome species, and although not discovered until 1887 and flowered under cult. in 1890, it is now much used as a parent in breeding. Several varieties are offered, as var. **maculàtus,** Lemoine, with fls. large, chrome-yellow, the inner surface of the reflexed segms. bearing a maroon-red spot. Var. **salmòneus,** Lemoine, with fls. saffron or salmon-color outside, the interior bright chrome-yellow, with fine purple lines. Var. **màjor,** Lemoine, large-fld., said to be a cross of *G. primulinus* and yellow *G. Lemoinei:* fls. chrome-sulfur-yellow with light brown marks on the interior of the segms.: plant strong. Var. **eréctus,** Lemoine. Erect, with large scarcely hooded chrome-yellow maroon-spotted fls. Var. **cóncolor,** Lemoine. Fls. large, 2 of the segms. sulfur-yellow and the remainder naples-yellow.

20. **sulphùreus,** Baker. Corm 1 in. diam., globose: stout, but low, the st. 1 ft.: lvs. 3–4, the blade short (2–3 in.) and somewhat ensiform: fls. 6–8, large, soft bright yellow, the curved tube 1½ in. long, upper segms. hooded, oblong or obovate, the 3 lower ones small; stamens shorter than upper segms. E. Trop. Afr.—The *G. sulphureus,* De Graaf (*G. Adlami,* Baker) is another species and the name is older. B.M. 7791.

21. **dracocéphalus,** Hook. f. Corm large, flattened-globose: st. stout and simple, 2 ft. or less: lvs. 3–4, rather firm, 1–1½ ft. long and 1 in. or less broad: fls.

3–6, of medium size, yellowish green, the tube (2 in. or less long) curved; upper segms. elliptic-obovate, hooded, yellowish and closely striate with purple, the other segms. much smaller and reflexing, mostly green and purple-spotted; stamens nearly equaling the segms. Natal. B.M. 5884.—Odd.

22. **psittacìnus,** Hook. (*G. natalénsis,* Reinw. *Watsònia natalénsis,* Eckl.). Corm very large, flattened-globose: st. 3 ft. or more, stout: lvs. about 4, rather rigid, 1–2 ft. long and 1–2 in. broad: fls. many and large, with a curved tube nearly or quite 2 in. long, in general effect rich yellow but thickly grained and overlaid with red (particularly about the margins of the segms.); upper segms. obovate and hooded, dark crimson, the lower much smaller and reflexing, red and yellow mixed. S. Afr., away from the coast. B.M. 3032. B.R. 1442. L. B. C. 18:1756.—One of the leading parents of garden gladioli.

23. **purpùreo-auràtus,** Hook. f. Fig. 1649. Corm large, globose: st. 3 ft., very slender: lvs. 3–4, short: fls. 10 or more, primrose-yellow, medium in size, the curved tube less than 1 in. long; segms. obovate, not widely spreading, the lower ones with a red-brown blotch; stamens reaching half-way up the limb. Natal. B.M. 5944. G.F. 2:89 (reduced in Fig. 1649).—Handsome. A parent of modern gladioli. Suggested by Baker as perhaps a color-variety of *G. Papilio.*

1650. Gladiolus turicensis. (×⅓)

cccc. *Under- or body-color white. (Forms of No. 13 may be sought here.)*

24. **blándus,** Ait. Corm medium size, globose: st. 2 ft. or less tall, sometimes branched: lvs. usually 4, 1 ft. or less long and ½–¾in. wide: fls. few, white and red-tinged, the curved tube 1½ in. long; segms. all oblong or oblong-spatulate and flaring or recurved, some of them red-marked in the throat; stamens more than half length of limb. S. Afr., coast region; variable. B.M. 625. Sometimes pure white. B.M. 648, *G. álbidus,* Jacq.; pink or flesh-color, B.M. 645; *G. cárneus,* Delar.; segms. white, with many pink markings, B. M. 3680, *G. Mortònius,* Herb.; taller, with longer lvs. and perianth-tube, *G. excélsus,* Sweet; pink fls. with red blotches on 3 lower segms., var. *Hibbertii,* Hort. *G. blandus* is an old garden plant.

25. **floribúndus,** Jacq. Corm globose: st. 2 ft. or less, often branched: lvs. usually 4, ensiform, 1–2 ft. long: fls. 12 or less, ascending, in a lax 2-sided spike, large, white tinged with pink, the slightly curved tube 2 in. or less long; segms. obovate or spatulate, obtuse or deltoid, wide-flaring, red-lined; stamens one-third or one-half length of limb. S. Afr., coast region; perhaps a form of *G. blandus.* B.M. 610.

26. **oppositiflòrus,** Herb. Much like the last, but fls. more numerous and smaller, white, sometimes marked with rose, the segms. oblong and distinctly pointed. S. Afr., in the eastern region. B.M. 7292. G.C. III. 13:291. Gn. 45:440.—A very handsome plant, growing 3–6 ft. high, and said to produce spikes 2 ft. long.

27. **Mílleri,** Ker (*Antholỳza spicàta,* Mill.). Corm medium size, globose: st. 12–20 in., simple: lvs. about 4, ensiform, shorter than the st.: fls. rather large, 4–5, nearly erect, milk-white, the tube 2 in. or less long and straight; segms. oblong and nearly acute; stamens one-third to one-half length of limb. S. Afr., coast region. B.M. 632.

II. Hybrids and Variants of Gladiolus in Cultivation.

The garden gladioli are derivatives of various kinds and degrees. Of many, the parentage is so confused that it cannot be made out. However, there were four early main lines of development or divergence, represented in the late-flowering *G. gandavensis, G. Lemoinei* and *G. nanceianus,* and the early-flowering *G. Colvillei.* To these have been added other lines in recent years.

28. **Cólvillei,** Sweet (*G. trìstis* var. *cóncolor* × *G. cardinàlis*). Fls. open or flaring, with oblong-acute segms.; scarlet, with long blotches at the base of the lower segms: early-flowering: spikes short. Hardy south of Washington with some protection. R.H. 1895, p. 289. G.C. III. 12:90. Gn. 28:566; 34:580; 50, p. 66. Gn.M. 4:189.—The oldest of the garden forms. Runs into many types and strains. The modern white-fld. type, var. *álbus,* represented by The Bride, is best known in this country. Small forms are known as *G. nànus:* Gn.W. 15:9; used for early flowering. Some forms are known as *G. floribúndus. G. delicatíssimus,* Blushing Bride, is a form of the same group: segms. white, with a large oval rose-crimson yellow-centered blotch on each of the 3 lower ones. Gn. W. 15:9. J.H. III. 49:213.

Another form of early-flowering gladioli is known as *G. ramòsus,* Paxt. (issue of *G. cardinalis* and *G. oppositiflorus*), but it is probably no longer possible to distinguish these two groups.

29. **gandavénsis,** Van Houtte (*G. psittacìnus* × *G. cardinàlis*). Fig. 1645. Upper segms. nearly or quite horizontal or hooded, the colors in bright shades of red and red-yellow, variously streaked and pencilled: late-flowering: spikes long. The commonest old-time type of garden gladiolus with the bloom much like that of *G. psittacinus* in form and size, but with a purer and better red. F.S. 2:84 (1846). R.H. 1846:141. P.M. 11:27. Gn. 64, p. 252. H.F. 1:208; 2:132. Gt. 59, p. 499 (var. *Europa,* with pure white fls.)—First offered to the trade by Van Houtte, Aug. 31, 1841. M. Souchet, of Fontainebleau, France, did much to improve the gandavensis type by repeated selections and breeding. By Herbert and some others, gandavensis is considered to be an offspring of *G. psittacinus* × *G. oppositiflorus.* Var. *citrìnus,* Hort., is like *G. psittacinus,* but the color is bright yellow. F.S. 5:539. *C. brenchleyénsis* is one of the gandavensis tribes; light red. *G. Hollándia* is a pink form of this.

30. **Lemòinei,** Hort. (*G. gandavénsis* × *G. purpùreo-auràtus*). Fig. 1646. A modern race characterized by highly colored yellow, red and purplish fls., purple-blotched on the lower segms. with a more or less bell-shaped form of corolla—the segms. broad and heavy and the upper ones horizontal or strongly hooded. Grown by M. Lemoine, Nancy, France, and first shown at the Paris Exhibition of 1878. Gn. 17:306; 30:76. R.H. 1879:330.—Fls. said not to open up so well when cut as do those of *G. gandavensis,* the st. being hard.

31. **nanceiànus,** Hort. (*G. Lemòinei* × *G. Saùndersii*). Fig. 1646. Robust, with very large, open-spreading fls.,

the 2 side segms. widely flaring and sometimes measuring 6–8 in. from tip to tip; upper segm. long and upright. First exhibited by Lemoine, the raiser, in 1889. The finest race, characteristically is full-open and large fls., in brilliant shades of red and purple. Gn. 41:190. G.C. III. 13:131. Gn. W. 7:797.

32. **Childsii** (*G. gandavénsis* × *G. Saùndersii*). Fls. wide open and large, with very broad petals: st. large and soft, taking up water well when fls. are cut. Originated by Max Leichtlin, Germany.

33. **Froèbelii,** Hort., is *G. purpùreo-auràtus* × *G. gandavénsis;* **G. Engésseri,** Hort., is of similar parentage; also **G. Brìneri,** Hort.

34. **turicénsis,** Hort. (Fig. 1650), is the offspring of a large-fld. *G. gandavensis* and *G. Saundersii* var. *superbus*. It is a fine purplish crimson, the lower segms. being beautifully marked with white: fls. 3 in. across. G.F. 3:89 (reduced in Fig. 1650).—This and the last 3 are the work of Froebel & Co., Zurich.

35. **prínceps,** Hort. (*G. hýbridus princeps*). Produced by W. W. Van Fleet, from seed of *G. cruentus* × *G. Childsii;* like the seed-parent in its scarlet-crimson coloring, with white and cream feather markings on the lower segms.: very large, the flat circular bloom expanding to 6 in. diam.: plant very large. G. 24:663; 34:533. Gn. 60, p. 197. G.M. 44:629.

36. **præcox,** Hort. Very early-flowering types, results of crossing of horticultural groups (p. 1340).

37. **Kúnderdii,** Hort. A strain or group of the ruffled or fluted kinds. See p. 1340.

Many species of Gladiolus are likely to be discussed in horticultural literature. The following have recently been prominently mentioned: *G. carmíneus,* C. H. Wright. Resembles R. ramosus, Paxt., but differs in its laxer habit, longer spathe and yellow anthers: slender, 1½ ft.: lvs. linear, acuminate, 8 in. long and ⅓in. broad: fls. carmine, about 3 in. across; tube narrow-funnel-shaped, white outside; segms. ovate, acuminate, 2 of the inner bearing a dark spot with a pale center; stamens rather more than half length of perianth. S. Afr. B.M. 8068.—*G. glaùcus,* Heldr. Dwarf, not exceeding 12 in.: st. and lvs. erect and stiff: fls. many, bluish red with red and white stripes at base. Greece.—*G. Mackínderi,* Hook. f. St. slender, 2 ft.: lvs. narrowly linear, the lower about 1 ft. long: fls. 5–6, the tube yellow, broad segms. scarlet and 1½ in. across. E. Trop. Afr. B.M. 7860. Named for Professor Mackinder, Oxford, who collected seeds at 10,000 ft. on Mt. Kenia in 1900. One of the Homoglossum section.

L. H. B.

1651. Glaucium flavum. (×⅓)

GLASSHOUSE. Any glass structure in which plants are grown, particularly one that is large enough to admit the operator. It is a generic term. See *Greenhouse.*

GLAÚCIUM (name refers to glaucous foliage). *Papaveràceæ.* Horned Poppy. Annual, biennial or occasionally perennial herbs, a few of which are grown for their large poppy-like flowers and glaucous-blue foliage.

Sepals 2; petals 4; stamens many; ovary with 2 (rarely 3) cells, the stigmas miter-shaped, the fr. becoming a long silique-like caps.: lvs. alternate, lobed or dissected.—A dozen or more species of S. Eu. and W. Asia.

Glauciums are low, branchy herbs, often somewhat succulent, with large flowers, mostly yellow or orange, but varying to red and purple. The flowers are usually short-lived, but they are borne in rapid succession. They are well adapted for foliage effects in borders or edgings. Of easy culture in any good soil. They prefer an open, sunny situation. Mostly propagated by seed, but the perennial kinds by division: however, the perennials are short-lived; and usually had best be treated as biennials; they should be grown from seed. Hybrids are announced by Burbank

flàvum, Crantz (*G. lùteum,* Scop.). Horn Poppy. or Sea Poppy. Fig. 1651. Sts. stout, 1–2 ft., pubescent: radical lvs. 2-pinnate and hairy the upper clasping and sinuate-pinnatifid and cordate at the base: fls. generally solitary, on long sts. 2–3 in. across, yellow or orange. Eu. C.L.A. 1:139. Gn. M. 9:86.—Sparingly naturalized E. Perennial or biennial; sometimes grown as an annual. Var. **tricolor,** Hort. (*G. tricolor,* Vilm.) has been advertised. It has parti-colored fls. and is showy. G.C. III. 36:115. G.M 48:697. Gn. 66, p. 59.

corniculàtum, Curt. (*G. phœníceum,* Gaert. *G. rùbrum,* Hort.). Lower: radical lvs. pinnatifid, pubescent, the upper ones sessile and truncate at the base: fls. red or purplish, with a black spot at the base of each petal. Eu.—Mostly annual. *G. Físcheri,* Hort., is probably a form of this.

leiocárpum, Boiss. A velvety perennial with oblong, sinuate-dentate, or much-divided lvs. which in the upper part of the plant are sinuate-lobed: fls. yellow, the calyx somewhat papillose. Medit. region.—Scarcely a showy member of the genus.

L. H. B.
N. Taylor.†

GLAÙX (Greek, *sea-green*). *Primulàceæ.* One small little pale herb, seldom seen in gardens, *G. marítima,* Linn. St. 9 in. or less high, erect or spreading, perennial by slender creeping rootstocks, growing in salt marshes and seacoasts from New Jersey and Calif. northward, and also in Eu. and Asia: lvs. oval to oblong-linear, entire and sessile, ½in. or less long: fls. purplish or white, the corolla wanting; calyx with 5 petal-like lobes; stamens and style exhibiting dimorphism: fr. a 5-valved few-seeded caps.

L. H. B.

GLAZIÒVA: *Cocos insignis.*

GLECHÒMA: *Nepeta*

GLEDÍTSIA (after Gottlieb Gleditsch, director of the botanic garden at Berlin; died 1780). Syn. *Gleditschia. Leguminòsæ.* Honey Locust. Ornamental trees grown chiefly for their handsome finely divided foliage; also the large conspicuous pods and the branched spines are attractive.

Deciduous, usually with large branched spines on trunk and branches: lvs. without stipules, alternate, abruptly pinnate, often partly bipinnate on the same lf. or wholly bipinnate, both usually on the same tree: fls. polygamous in racemes or rarely panicles; calyx-lobes and petals 3–5, petals nearly equal, not much longer than calyx, stamens 6–10; style short, with large terminal stigma: pod compressed, mostly large and indehiscent, 1- to many-seeded.—About 12 species in N. Amer., E. and Cent. Asia, in Trop. Afr. and in S. Amer.

The honey locusts are large trees with spreading branches forming a broad graceful rather loose head, with finely pinnate foliage, generally light green and turning clear yellow in fall; the greenish flowers appearing in racemes early in summer are inconspicuous, but the large, flat pods are ornamental and the fertile tree is therefore to be preferred for planting. *G. triacanthos* is a useful native and is hardy North; *G. japonica* is almost hardy North, while *G. Delavayi* and *G. sinensis* are tender. They are very valuable trees for park planting and for avenues, and make almost impenetrable hedges if planted thickly and pruned severely. The coarse-grained wood is durable and strong. The pulp of the pods of *G. triacanthos* is sweet when fresh, hence the name honey locust, but becomes bitter at length; that of *G. japonica* is used in Japan and that of *G. sinensis* and *G. macracantha* in China as a substitute for soap. The gleditsias are of vigorous growth and thrive in almost any soil; they stand drought well. Propagation is by seeds sown in spring about 1 inch deep; they should be soaked in hot water before being sown; varieties and rare kinds are sometimes grafted on seedlings of *G. triacanthos* in spring.

1652. Gleditsia triacanthos. (×⅓)

A. *Spines more or less compressed, at least at the base: walls of pod papery or leathery: lvs. pinnate with more than 12 lfts., or bipinnate.*

B. *Pod 1–2-seeded, oval, not pulpy.*

aquática, Marsh. (*G. inérmis*, Mill., not Linn. *G. monospérma*, Walt.). WATER or SWAMP LOCUST. Tree, to 60 ft., with short trunk, spiny: lvs. 12–18-foliolate or doubly pinnate with 6–8 pinnæ; lfts. ovate-oblong, usually rounded or sometimes emarginate at the apex, slightly crenate and often entire below the middle, glabrous except a few hairs on the petiolules, about 1 in. long: fls. in racemes; ovary glabrous: pods long-stalked, 1–2 in. long. May, June. S. C. and Ky. to Fla. and Texas. S.S. 3:127, 128.

BB. *Pod many-seeded, elongated and usually more or less twisted, pulpy.*

C. *Lfts. usually acute or acutish, often more than 20, not over 1½ in. long: ovary pubescent.*

triacánthos, Linn. HONEY or SWEET LOCUST. THREE-THORNED ACACIA. Fig. 1652. Tree, 70–140 ft., usually with stout simple or branched spines 3–4 in. long: lvs. 6–8 in. long, with pubescent grooved rachis; pinnate with 20–30 lfts., bipinnate with 8–14 pinnæ; lfts. oblong-lanceolate, remotely crenulate-serrate, ¾–1½ in. long: fls. very short-pedicelled in 1½–3 in. long, narrow racemes; ovary pubescent: pod 12–18 in. long, slightly falcate and twisted at length. May, June. From Pa. south to Miss., west to Neb. and Texas. S.S. 3:125, 126. Gn. 32, p. 304. Var. **inérmis**, Pursh. Unarmed or nearly so, of somewhat more slender and looser habit; var. **inérmis elegantíssima**, Grosdemange, is an unarmed form of dense bushy habit and with smaller lfts. R.H. 1905, p. 513. Var. **Bujòtii**, Rehd. (*G. Bujòtii*, Neum. *G. Bujòtii péndula*, Hort.). With slender, pendulous branches and narrower lfts.

CC. *Lfts. obtuse or emarginate, usually less than 20: ovary glabrous or only pubescent on the margin.*

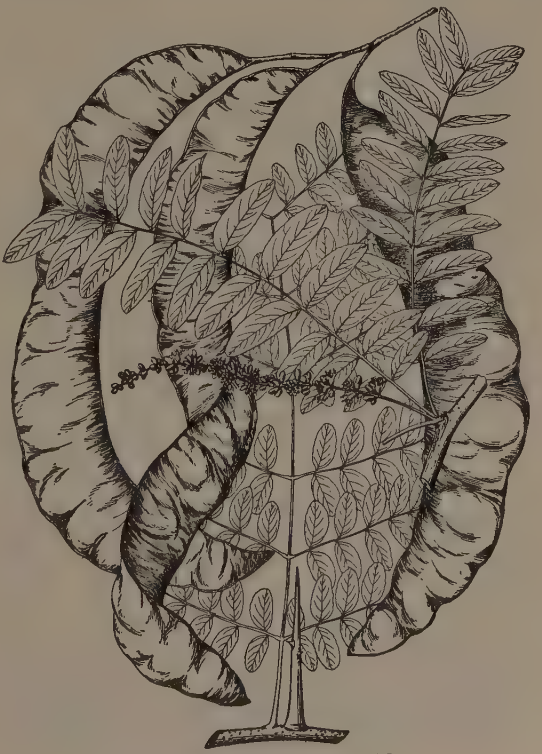
japónica, Miq. (*G. hórrida*, Makino). Fig. 1653. Tree, 60–70 ft., with somewhat compressed, often branched spines, 2–4 in. long: lvs. 10–12 in. long, with grooved and slightly winged, puberulous rachis, pinnate with 16–20 lfts., bipinnate with 8–12 pinnæ; lfts. ovate to oblong, nearly lanceolate, obtuse, entire or remotely crenulate, lustrous above, ¾–2 in. long: fls. short-pedicelled, in slender racemes: pod 10–12 in. long, twisted, bullate, with the seeds near the middle: pulp acid. Japan, China. G.F. 6:165 (adapted in Fig. 1653). Var. **purpùrea**, Rehd. (*G. sinénsis* var. *purpùrea*, Loud. *G. coccínea*, Hort. *G. sinénsis* var. *orientàlis*, Hort.). Lfts. broadly oval to oblong-oval, obtuse or emarginate, ½–1½ in. on the pinnate, smaller on the bipinnate lvs.

Delavàyi, Franch. Tall tree: spines compressed at the base, to 10 in. long: lvs. 12–18-foliolate, only on young plants partly bipinnate; lfts. obliquely ovate or ovate-oblong, obtuse or emarginate, slightly crenate or nearly entire, dark green and lustrous above, glabrous, to 2½ in. long, the lower much smaller, also much smaller on young plants: fls. in slender racemes; ovary glabrous: pod with leathery walls, to 15 or sometimes to 20 in. long and to 2⅓ in. broad, twisted. S. W. China.—Very handsome; recently intro.

AA. *Spines terete: walls of pod thick, woody; pod straight or falcate, not twisted: lvs. 8–16-foliolate, very rarely bipinnate.*

sinénsis, Lam. (*G. hórrida*, Willd.). Tree, to 40 ft., with stout conical often branched spines: lvs. 5–7 in. long, with grooved pubescent rachis, and 8–18 lfts.; lfts. ovate or oblong-ovate, obtuse or acute, crenulate-serrate, yellowish green, dull above, reticulate beneath, ¾–2 in. long: fls. distinctly pedicelled, in slender racemes; ovary glabrous: pod almost straight, thick, 4–7 in. long, 1–1½ in. broad. China. Var. **nàna**, Loud. Shrubby and less spiny, with smaller and narrower lfts.

G. amorphoìdes, Taub. (Garugandra amorphoides, Griseb.). Tree, to 50 ft., very spiny: lfts. obliquely ovate to linear-oblong, ½–1 in. long: fls. in racemes: pod oblong, falcate, 3–4 in. long, 1 in. broad, ½ in. thick. Argentina, Bolivia. Cult. in Calif.—*G. austràlis*, Hemsl. Tree with large spines: lfts. very oblique, oblong, crenate, leathery, shining: pod with coriaceous walls, 4–5 in. long. S. China. —*G. cáspica*, Desf. (G. horrida var. caspica, Schneid.). Allied to G. japonica. Lvs. pinnate with 12–20 ovate, crenulate lfts., or bipin-



1653. Gleditsia japonica. (×⅓)

nate with 6–8 pinnæ: pod thin, pulpy, to 12 in. long.—*G. fèrox*, Desf. Allied to G. sinensis. Spines very stout: lvs. 16–30-foliolate; lfts. oblong-ovate to oblong-lanceolate, crenate, ½–1½ in. long: pod to 10 in. long. China. Most plants cult. under this name seem to belong to G. japonica.—*G. Fontanèsii*, Spach=G. macracantha.—*G. heterophýlla*, Bunge. Allied to G. aquatica: lfts. obliquely obovate, pubescent below, ½–¾in. long: pod oval, 2–3-seeded, slender-stalked, about 1 in. long. N. China. Probably quite hardy.—*G. macracántha*, Desf. Allied to G. sinensis. Spines and lfts. generally larger: infl. paniculate; ovary pubescent: pod 4–6 in. long, ¾in. broad, often almost cylindrical. China.—*G. officinàlis*, Hemsl. Allied to G. sinensis. Spiny tree, to 40 ft.: lfts. 12–20, obliquely elliptic to elliptic-oblong, acutish, to 3½ in. long: pod oblong, thick, falcate, 3–4 in. long and little over ½in. broad. Cent. China.—*G. texàna*, Sarg. Allied to G. triacanthos. Lvs. 12–22-foliolate, often bipinnate: pod narrow-oblong, straight, 4–5 in. long. Texas. S.S. 13:627. Possibly hybrid of G. aquatica and G. triacanthos.

Alfred Rehder.

GLEICHÈNIA (W. F. Von Gleichen, 1717–1783). *Gleicheniàceæ.* Ferns mainly from the tropical and south temperate zones, growing naturally in dense thickets; one species has recently been found in Louisiana, *D. flexuosa.* (Amer. Fern Jour. 4:15).

The family is characterized by dorsal sori composed of a few nearly sessile sporangia; each sporangium is surrounded by a broad transverse ring, and opens vertically. The most striking thing about the family is the growth of the lvs. The lvs. of many of the species are perennial and show an indeterminate growth. During the growing season, the end of the lf. will keep unrolling after the usual manner of ferns. During the resting season this tip rests, but resumes its growth the next season. The lvs. of some species may thus become over 100 ft. in length. The species after the third (AA) are often catalogued under Mertensia, a name which, because used for a genus of flowers, must give way to Dicranopteris if they are separated and placed in a distinct genus, where they probably belong.

A. *Ultimate lobes small, roundish.*

B. *Sorus of 3–4 sporangia, superficial.*

rupéstris, R. Br. Lobes rounded or obtusely quadrangular, the margins thickened and recurved, somewhat glaucous beneath. Austral. Var. **glaucéscens**, Moore, has lvs. of thicker texture, which, when young, are very glaucous on both sides, contrasting with the reddish purple stalks.

circinàta, Swartz. Lobes ovate or rotund, with the rachides pubescent when young; 3–5 times forking, the ultimate pinnules 1 in. long. Austral., New Zeal.

Var. **spelúncæ**, Hort. (*G. spelúncæ*, R. Br.). Lvs. pendent but not curving; pinnules curved inward, forming small cavities. Var. **semivestìta**, Labill. (*G. semivestìta*, Hort.), differs in its close and very erect habit, and flat, deep green pinnæ. Var. **Méndellii**, Moore (*G. Méndellii*, Hort.). More robust and compact than the type, with flat, thicker and glaucous lvs. Gn. 51, p. 472.

BB. *Sorus of 2 sporangia concealed in slipper-shaped lobes.*

dicárpa, R. Br. Lvs. 2–4 times forked, with the lobes strongly arched, rotund or narrow, with the under surface rusty-hairy. Austral.

AA. *Ultimate lobes pectinate: sori near the middle of the veinlets.*

B. *Lf. after first forking, bipinnate.*

glaùca, Hook. Primary branches elongate, 2–3 ft. long: rachises with rusty scales; pinnæ 4–8 in. long, with closely placed entire segms., glaucous beneath. China and Japan.

BB. *Lf. with fan-shaped divisions.*

flabellàta, R. Br. Lvs. 2–3 times forked, the divisions ascending, 6 in. or more long, elliptic-lanceolate; ultimate divisions linear. Austral.

longipinnàta, Hook. Branches of the lvs. repeatedly dichotomous; pinnæ up to 2 ft. long, 3 in. wide. Trop. Amer.

AAA. *Ultimate branches with a pair of forked pinnæ: lf.-sts. zigzag, repeatedly dichotomous.*

dichótoma, Willd. With a distinct pair of pinnæ arising from the base of the forked branches; segms. not decurrent. Tropical regions generally, but several species have been confused here, as in many of the widely distributed species.

L. M. Underwood.
R. C. Benedict.†

GLIRICÌDIA (*rodent-poison*, from the seeds). *Leguminòsæ.* Eight or 10 woody plants, Cuba and Mex., to S. Amer., differing from Robinia in the wingless or marginless pods and coriaceous valves. Lvs. odd-pinnate, the lfts. entire: fls. rose-colored, racemose or fasciculate; calyx-teeth short and broad, the 2 upper ones joined; standard large, reflexed; wings falcate-oblong; keel incurved, obtuse; ovary stipitate, many-ovuled, becoming a broad-linear 2-valved pod. **G. platycárpa**, Griseb., of Cuba, is offered in S. Fla.: tree, to 25 ft.: lfts. 7–9, ovate or ovate-oblong, glabrous, the margins undulate: corolla pink or purplish; stigma ciliate: pod sessile, plano-compressed, lanceolate-oblong, 8-seeded. **G. maculàta.** HBK. (*Lonchocárpus maculàtus*, DC.), Guatemala to S. Amer., is reported as in cult. in S. Fla.: small tree: lfts. about 17, oblong, obtuse, somewhat appressed-pilose above and blackish-spotted and glaucescent beneath: pod linear, compressed, with thickened margin.

L. H. B.

GLÓBBA (Malayan name). *Zingiberàceæ.* Herbaceous conservatory plants with rhizomes and habit of canna, and a singular floral structure.

Flowers in terminal panicles; bracts usually deciduous; calyx funnel-shaped, 3-lobed; corolla-tube longer than the calyx, the lobes nearly equal, ovate; staminoid petal-like and fastened to the corolla-lobes; ovary 1-celled, forming a globose, tardily dehiscing caps.—Only one species is known to be cult. in Amer. This is known as *G. coccinea*, which is really *G. atrosanguinea*, figured at B.M. 6626. "Index Kewensis" is clearly in error in referring *G. coccinea* to *G. albo-bracteata*, as is plain from G.C. II. 18:71. Veitch intro. in 1881 a plant under the provisional name of *G. coccinea*, as it was supposed to be a new species, but the next year, it was identified with *G. atrosanguinea*. This plant was highly praised in 1893: "Plants in bloom the greater part of the year: sts. much crowded, 12–18 in. long, gracefully arching on all sides: fls. scarlet and yellow, in dense racemes." The credit for the discovery of this plant is generally given to F. W. Burbidge, but in G.C. II. 18:407, Burbidge gives the honor to Curtis. For cult., see *Alpinia*.

atrosanguínea, Teijsm. & Binn. (*G. coccinea*, Hort., Veitch). St. slender, becoming 2–3 ft. high: lvs. 3–4 in. long, elliptic, acuminate at both ends; sheaths purplish, pubescent, closely clasping the st.; lower flowerless bracts distant, brown, 6–9 lines long, upper and flowering bracts crowded, red: fls. 1½ in. long; corolla yellow, tubular, thrice as long as calyx. Borneo. B.M. 6626. G.Z. 27, p. 121.—Little known in Amer. outside of botanic gardens.

N. Taylor.†

GLOBE AMARANTH: *Gomphrena.*

GLOBE FLOWER: *Trollius.*

GLOBE HYACINTH: *Muscari.*

GLOBE THISTLE: *Echinops.*

GLOBE TULIP: *Calochortus.*

GLOBULÀRIA (the flowers in small, globular heads). *Globulariàceæ.* Herbs, subshrubs and shrubs, with small blue flowers mostly in spherical heads.

Leaves from the root or alternate, leathery, entire or with a few sharp teeth: fls. small, blue, in dense heads; calyx 5-lobed, sometimes obscurely 2-lipped; corolla-tube usually short, broad at the throat, the lobes oblique or unequal; stamens 4, didynamous, attached at the throat: fr. small, included in the calyx.—About a dozen species from the Old World. Probably the commonest and best species is *G. tricosantha*, which thrives at the front of well-drained borders, but is particularly showy in the rockery. For this and *G. vulgaris* and its forms, rather moist but well-drained soil and partial shade are advised. Prop. by division or seed.

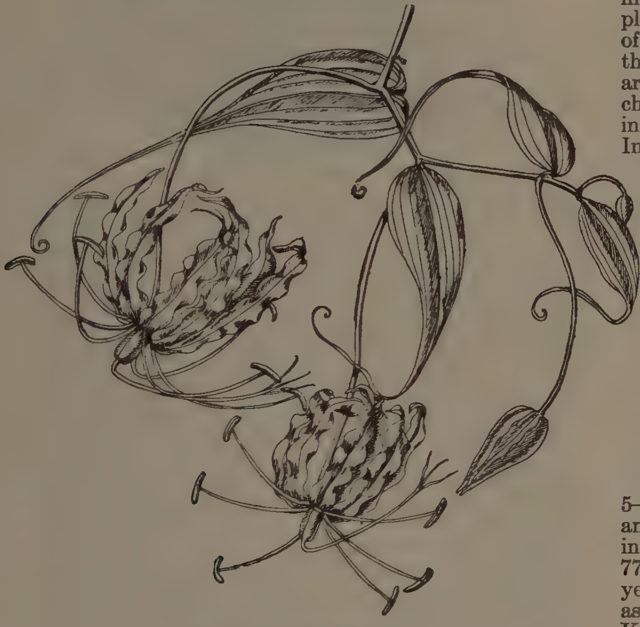
A. *Hardy herbaceous plants about 6–12 in. high.*

B. *Root-lvs. 1-nerved.*

trichosántha, Fisch. & Mey. Height 6 in.: root-lvs. spatulate, 3-toothed at apex; st.-lvs. obovate or oblong, mucronate, sessile. July, Aug. Asia Minor. Syria.

BB. *Root-lvs. 5-nerved.*

vulgàris, Linn. (*G. nudicaùlis*, Hort.). Height 8–12 in.: root-lvs. obovate, petiolate, nearly entire, apex entire, notched or mucronate; st.-lvs. lanceolate, sessile. S. Eu., Caucasus. July, Aug. B.M. 2256.



1654. Gloriosa superba. (×½)

AA. *Prostrate, woody herb, forming mats.*

cordifòlia, Linn. A low prostrate perennial with creeping, almost woody sts., and wedge-shaped, notched lvs., which form rosettes at the base of the solitary pedicel: fls. in a close head, not showy. S. Eu.—Useful for the rockery.

G. Alỳpum, Linn. Lvs. obovate-oblong, mucronate or 3-toothed at apex. Medit. regions.—Cult. years ago in S. Calif. by Franceschi, who says it is covered with fls. all winter; but not now in cult. Also cult. abroad under glass.—*G. bellidifòlia*, Salisb. = G. spinosa.—*G. spinòsa*, Linn. One ft. and more: radical lvs. obovate, attenuate into petiole, 3–7-toothed at apex; st.-lvs. lanceolate and sessile: head larger than in G. vulgaris; calyx 2-lipped, the tube ciliate and throat barbed; upper lip of corolla 2-parted, lower 3-parted. Spain.

N. Taylor.†

GLOCHÍDION (from Greek for *point*, the anthers being long-pointed). *Euphorbiàceæ.* Tropical trees or shrubs, rarely cult. Lvs. alternate, simple: fls. in axillary clusters or singly; staminate calyx imbricate, of 3–8 sepals; pistillate fls. without disk, stigmas short and thick, ovules 2 to each cell: fr. a caps.—About 135 species of Trop. Asia and Pacific islands, related to Phyllanthus.

J. B. S. Norton.

GLONÈRIA: *Psychotria.*

GLORIÒSA (Latin for *glorious*). Syn., *Methónica. Liliàceæ.* Tall, weak-stemmed plants, supporting themselves by means of tendril-like prolongations of the leaves. Odd and handsome plants, to be grown in a warmhouse.

Leaves oblong, lanceolate or lance-ovate: fls. many and showy, long-stalked, borne singly in the axils of the upper lvs.; perianth of 6 distinct long segms. which are undulate or crisped, and reflexed after the manner of a cyclamen, variously colored; stamens 6, long and spreading, with versatile anthers; ovary 3-loculed; style long, and bent upward near the base.—Five or perhaps more tropical species, all African, and 1 also Asian.

Gloriosas are not difficult to grow. The brightest flowers are produced in sunlight. The plants grow from tubers. These tubers should be rested in early winter, and started in pots in January to March. The plants bloom in summer and fall. When potting the old tubers, offsets may be removed (when they occur) and grown separately for the production of new plants. The tubers may be cut in two for purposes of propagation. Let the plants stand near a pillar or other support. Give freely of water when the plants are growing. In this country they are sometimes bedded out in summer. Gloriosas are sometimes grown outdoors in summer in Massachusetts, and the plants so treated are not much inclined to climb and flower so freely as under glass. In Florida, they may be grown permanently in the open. Success with gloriosa depends on having strong bulbs. Consult *Bulbs.*

A. *Perianth-segms. about 2½ in. long.*

Cársonii, Baker. St. erect and climbing, the lvs. st.-clasping, about 4–5 in. long, bearing long tendril-like processes: fls. very numerous, in a loose cyme; perianth-segms. not more than 2½ in. long, usually less than that, recurved and crisped, the margins yellow; style erect; stigmas 3.—F.S.R. 2, p. 355. A showy plant from Cent. Afr. Intro. in 1904.

AA. *Perianth-segms. longer than 3 in.*

B. *Segms.* (*or petals*) *much crisped.*

supérba, Linn. Climbing Lily. Fig. 1654. St. 5–10 ft. high: lvs. ovate-lanceolate: segms. 2–3 in. long and less than an inch wide, opening yellow, but changing to yellow-red and deep scarlet. Afr., Asia. B.R. 77. Gn. 38:576. B.H. 23:121. G.L. 18:277.—A yellow-fld. form of unknown origin has been described as *G. lùtea*, Hort; it is scarcely known outside of Kew. Var. **grandiflòra,** Hort., is advertised as "color a yellow-red, changing to deep scarlet;" it is unknown in the wild state.

BB. *Segms. somewhat undulate, but not crisped.*

símplex, Linn. (*G. viréscens*, Lindl. *G. Plántii*, Loud.). Fls. opening yellow, and remaining so in shade, but becoming deep yellow-red when exposed to the sun; wider than in *G. superba*, barely undulate and wavy, and not prolonged or hooked at the end as in the latter species. Afr. B.M. 2539. G. 26:556. Var. **grandiflòra,** Nichols. (*Methónica grandiflòra*, Hook.), has fls. 8 in. across. B.M. 5216. G. 27:477.

Rothschildiàna, O'Brien. St. climbing, simple at first, afterward branched: lvs. bright green, glabrous, oblong-acuminate, alternate or opposite: fls. solitary in the axils, or peduncles 3–4 in. long, abruptly curved near the ovary; perianth-segms. oblong-lanceolate, recurved, over 3½ in. long, crimson, with a dark purple mark near the base. Trop. Afr.—One of the best species. G.C. III. 33:323. G.M. 47:377. Gn. 65, p. 451. G.W. 9, p. 112; 13, p. 535. R.B. 34:339. F.S.R. 2:248. Var. **citrìna,** Hort., has fls. citron-yellow and claret-purple. It is a splendid showy addition. G.C. III. 38:211.

G. abyssínica, Rich., said to be the largest-fld. species, seems not to be in cult.—*G. Lèopoldii*, Hort., a beautiful form with yellow and purple fls., is probably some form of G. simplex grandiflora. G.C. III. 36:188. R.H. 1903:548.

N. Taylor.†

GLORY-OF-THE-SNOW: *Chionodoxa.*

GLORY PEA: *Clianthus.*

GLOSSOCÒMIA CLEMATÍDEA: *Codonopsis clematidea.*

GLOXINÈRA (*Gloxinia* and *Gesneria*). *Gesneriàceæ.* A bigeneric hybrid between *Gesneria pyramidalis* (seed-parent) and Gloxinia Radiance, by Veitch and first exhibited at the Royal Horticultural Society, London, May 8, 1894. It has the habit of a garden gloxinia, with inclined fls. of fair size, brilliant scarlet tinged with magenta in the shadows. The foliage is recorded as more nearly that of a gloxinia than a gesneria in appearance, being very succulent and covered with fine hairs. G.C. III. 17:145.

GLOXÍNIA (named for P. B. Gloxin, of Strassburg, who wrote in 1785). *Gesneriàceæ.* The genus Gloxinia was founded by L'Heritier in 1785 upon *G. maculata* of Brazil. Early in last century a related Brazilian plant was introduced, and it attracted much attention: this plant was named *Gloxinia speciosa* by Loddiges in his Botanical Cabinet in 1817, and it was there figured. In the same year it was figured by Ker in the Botanical Register, and also by Sims in the Botanical Magazine. Sims wrote that the plant was "already to be found in most of the large collections about town [London]." These writers refer the plant to the Linnæan class Didynamia, but Ker also suggests that it may belong to the Campanulaceæ. This *Gloxinia speciosa* was the forerunner and leading parent of the garden gloxinias, but it turns out that the plant really belongs to Nees' genus Sinningia, founded in 1825 on a Brazilian plant which he named *S. Helleri;* but the rules of nomenclature make the tenable name to be **Sinníngia speciòsa,** Benth. & Hook. (See *Sinningia.*) All the garden gloxinias are therefore sinningias, but to gardeners they will ever be known as gloxinias; therefore, the evolution of them may be traced here.

1655. Modern gloxinia blooms.—Sinningia speciosa. (×⅓)

Gloxinia has no tubers: Sinningia has a tuberous rhizome. Gloxinia has a ring-like or annual disk about the ovary: Sinningia has 5 distinct glands. The sinningias are either stemless or st.-bearing, with a trumpet-shape or bell-shape 5-lobed and more or less 2-lipped corolla, a 5-angled or 5-winged calyx, 4 stamens attached to the base of the corolla, and with anthers cohering at the tips in pairs, and a single style with a concave or 2-lobed stigma. The garden gloxinias belong to the subgenus Ligeria (subgenus of Sinningia), which has a short st. or trunk, and a broad-limbed bell-shape fl. Gloxinia has perhaps a half-dozen species from Mex. to Brazil and Peru; Sinningia has about 20 species, in Brazil.

1656. A good gloxinia plant.

The true gloxinias are not florists' flowers, and they are little known in cultivation. They are apparently not in the American trade. The old *G. maculata* is figured in the Garden 39:801 (p. 364), and it is probably to be found in choice collections in the Old World. It produces knotty rootstocks, which, as well as the leaves, may be used for propagation. It is also figured in B.M. 1191. *G. glabrata*, Zucc., from Mexico, is the *G. glabra*, Hort., *Achimenes gloxiniæflora*, Forkel, and *Plectopoma gloxiniflorum*, Hanst. It is a stemmy plant, bearing white flowers with yellow-spotted throat; B.M. 4430, as *G. fimbriata*, Hook. Plectopoma is now referred to Achimenes, and the plant then takes the name *Achimenes glabrata*, Fritsch. It appears not to be in the trade. Other related genera are Diastema, Dicyrta and Isoloma.

The garden gloxinias (genus *Sinningia*) are nearly stemless plants, producing several or many very showy bell-like flowers, each on a long stem. *G.* (*Sinningia*) *speciosa* originally had drooping flowers, but the result of continued breeding has produced a race with flowers nearly or quite erect (Figs. 1655, 1656). The deep bell of the gloxinia is very rich and beautiful, and the erect position is a decided gain. The flowers also have been increased in size and number, and varied in shape and markings; the leaves also have become marked with gray or white. The color of the original *Gloxinia* (*Sinningia*) *speciosa* was a nearly uniform purple. The modern races have colors in white, red, purple and all intermediate shades, some are blotched, and others are fine-spotted or sprinkled with darker shades. It is probable that the larger part of the evolution in the common greenhouse gloxinia is a direct development from the old *G. speciosa*, but hybridity may have played a part. One of the earliest recorded series of hybrids (1844) was with *Sinningia guttata*, which is a plant with an upright stem and bearing rather small spotted flowers in the axils of the leaves. (B. R. 1112.) The issue of this cross showed little effect of the *S. guttata*, except a distinct branching habit in some of the plants (B.R. 30:48). It is possible, however, that *S. guttata* has had something to do with the evolution of the spots on the present-day flower, although the original *G. speciosa* was striped and blotched in the throat. The student who wishes to trace some of the older forms of garden gloxinias may look up the following portraits: B.M. 1937, speciosa itself; B.M. 3206, var. albiflora; B.M. 3934, var. macrophylla variegata; B.M. 3943, var. Menziesii; F.S. 3:220, Teichleri (hybrid); F.S. 3:268; F.S. 4:311, Fyfiana (hybrid); F.S. 6:610; F.S. 10:1002; F.S. 14:1434–6; F.S. 16:1699 and 1705; F.S. 17:1768, 1772–6; F.S. 18:1846, 1878, 1885, 1918, 1919; F.S. 19:1955, double forms; F.S. 21:2164; F.S. 22:2324. I.H. 42:39, 41. Gt. 47, p. 79; Gt. 48, p. 80. Gn. 15:162; 43:392; 52, p. 268. R.H. 1846:301, Teuchlerii; R.H. 1848:201, Fyfiana; 1877:70, variabilis; R.H. 1883, p. 248. For florists' plants, see A.F. 11:7; A.G. 14:49; Gng. 6:83. There are many Latin-made names of garden gloxinias, but the plants are only forms of the *G. speciosa* type. One of the trade entries is *G. crassifolia*, a name applied to some of the best and largest-growing strains.

There are double forms of gloxinia, in which an outer but shorter corolla is formed. The forms are more curious than useful. L. H. B.

Cultivation of gloxinia.

Few flowers can surpass the large tubular blooms of gloxinia for richness and variety of coloring. The colors range through all the shades of blues and purples, pinks and crimsons, while some are pure white, and others again white with tinted edges; still others have the colors dotted on the lighter ground-color. The foliage also of gloxinias is very beautiful, being of a rich soft velvety texture. Gloxinias make a gorgeous display, therefore, when in flower and are especially valuable for the decoration of conservatories during the summer and early fall months.

Gloxinias are native of tropical America and therefore require a warm greenhouse or tropical temperature in the growing season. When first introduced into cultivation, and even for many years after, the flowers of gloxinias were all nodding, that is they hung down instead of standing upright; no one now grows the nodding-flowered kinds, the upright-flowered being so much more attractive.

Though they may be grown so as to flower at almost any season of the year, yet they are naturally summer-flowering plants, and do best when treated as such. They are propagated by seeds, or by cuttings made of leaves or stems. Seeds are preferable, unless one wishes to increase some very choice colored variety, when it is best to propagate by leaf-cuttings, using partly matured medium-sized leaves with a small portion of leaf-stalk attached (Fig. 1176, p. 929). These may be inserted in an ordinary propagating-bed, where if kept rather on the dry side, they will soon root and form tubers, when they may be potted and grown on. Seeds should be sown in a warm temperature early in February, in pans or shallow boxes containing a finely sifted mixture of peat, leaf-mold and silver sand in about equal proportions. The seedlings will begin to appear in about ten days, when great care must be exercised in watering, or they will "damp-off." In fact, success with these plants throughout the year depends largely upon the care exercised in watering. Even in their most active growth the water always should be given from the spout of a watering-can, taking care not to wet the leaves, though they like a warm, humid atmosphere during their growing season. As soon as the seedlings can be conveniently handled, they should be potted singly into thumb-pots and grown on rapidly, using in subsequent shifts a mixture of two parts leaf-mold, one part good fibrous loam and one part peat. The plants must be well shaded from sunlight and placed in a position free from draughts. The seedlings should begin to flower by the middle of August, when they should be given an abundance of air. After flowering, the leaves will begin to mature, when water should be gradually withheld. As soon as the leaves have all ripened off, the pots should be stored away in some convenient place for the winter, in a temperature of about 45°, giving just sufficient water to keep the tubers from shriveling. Toward the middle of February the tubers will show signs of starting into growth. A batch should be started at this time, choosing the tubers which appear most active, and the remainder should be held back for another month; this will give a much longer period of blossoming. The tubers should have all the old soil shaken off and be potted again in clean well-drained pots, using sizes just large enough to accommodate the tubers, the compost being the same mixture as before recommended. They should be given but little water until active root-growth commences. As soon as the pots are filled with roots, they should be shifted on at once into the pots they are intended to flower in, as frequent shifts would more or less damage their leaves, which have a tendency to cling round the sides of the pots. The first batch should come into flower in June.

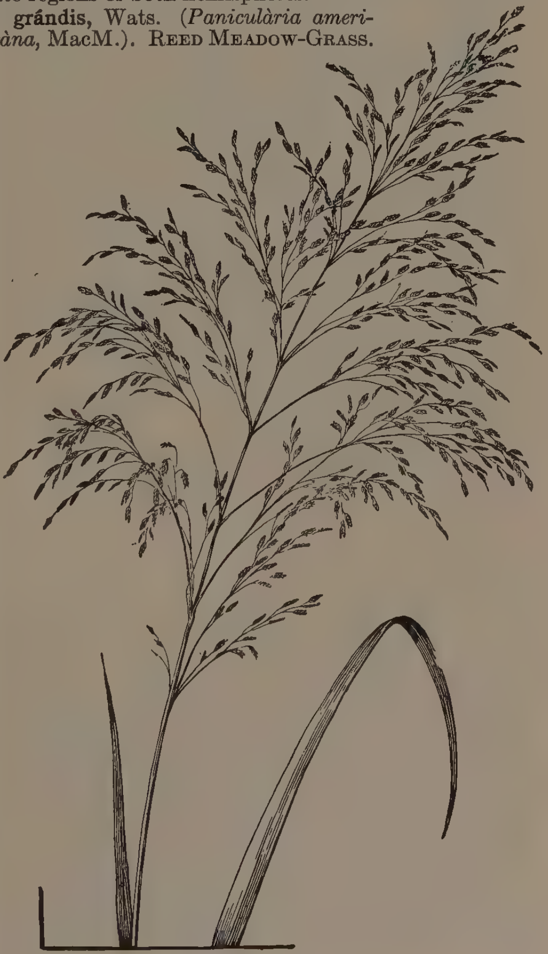
When carefully grown, gloxinias are particularly free from insect pests or fungous diseases, and the same tubers can be grown for several years.

Edward J. Canning.

GLYCÈRIA (Greek, *glukeros*, sweet). *Gramíneæ.* Marsh perennials with open (or rarely contracted) panicles, sometimes grown for ornament.

Spikelets few- to many-fld.; lemmas convex, firm, with a scarious margin or apex, usually obtuse, awnless, prominently 5–9-nerved.—Species about 16 in temperate regions of both hemispheres.

grándis, Wats. (*Paniculària americàna*, MacM.). Reed Meadow-Grass.



1657. Glyceria grandis. (×⅓)

Fig. 1657. Three to 5 ft.: lower sheaths rough and overlapping; blades 3–8 lines wide; glabrous: panicle 8–16 in. long, many-fld., open and spreading; spikelets 4–7-fld., 3 lines long. Dept. Agric., Div. Agrost. 7:286. N. U. S.

nervàta, Trin. (*Paniculària nervàta,* Kuntze). Fowl Meadow-Grass. One to 3 ft.: blades 1–2½ lines wide, scabrous above: panicle 4–8 in. long, open, the branches drooping; spikelets 3–7-fld., 1 line long. Ibid 287.—Widely distributed in U. S. A. S. Hitchcock.

GLYCÌNE (Greek for *sweet*). *Leguminòsæ.* The soybean and related plants. The glycines are allied to Dolichos, Vigna and Phaseolus: the cult. species are distinguished by small and hairy fls. in short axillary racemes: stipules very small and free from the petiole: lfts. 3, large.—Perhaps 40 species, mostly tropical, in Asia, Afr., and Austral., nearly all twining vines. In this country Glycine is known only in the soybean, **G. Sòja,** Sieb. and Zucc., which is an erect, hairy annual from Japan and China. It is also known as the soja or soya bean, coffee bean and coffee berry. It grows 2–6 ft. high, making a rank, bushy herb, and bearing axillary clusters of small hanging, hairy pods, with constrictions between the seeds. Fls. small, white or purple. The seeds are subglobose to oblong, yellow, green, brown or black, but in some varieties parti-colored. In China and Japan the beans are much used for human food and for the production of oil. For the latter purpose great quantities of seed have been exported in recent years from Manchuria to Eu. In this country the plant is grown for forage, its first use for this purpose dating from 1854. Since 1882, and especially since 1898, the crop has been steadily gaining in importance. The beans may be used as a substitute for coffee; and for this purpose the plant is often sold. The erect form of soybean is unknown in a wild state. It is clearly a domesticated form of **G. ussuriénsis,** Regel & Maack, which is wild in Japan, Manchuria, China, and India. For the economic merits of soybeans, see various experiment station reports; also Farmers' Bull. No. 372, U. S. Dept. of Agric. For a technical exhaustive paper see Bureau of Plant Industry, Bull. No. 197. The soybean has also been made the basis of a distinct genus under the name of Soja, Moench. Glycine was clearly used by Linnæus to refer primarily to the ground-nut, *Apios tuberosa.* Botanists who accept Glycine in that sense use Soja for the soybean and allied species. The plant named *Phaseolus max* by Linnæus is the soybean, and as the description is on a previous page to that of *Dolichos Soja,* some authors use the specific name *max* and designate the soybean as *Soja max.*

G. chinénsis = Wistaria sinensis. — *G. frutéscens* = Wistaria speciosa.—*G. sinénsis*=Wistaria. C. V. Piper.†

GLYCÓSMIS (from the Greek for *sweet,* and *smell*). *Rutàceæ.* Thornless shrubs or small trees, grown for ornament.

Leaves persistent, alternate; lfts. 1–9, alternate or nearly opposite, dark green above, pale below, coriaceous, entire or obscurely crenulate: fls. in axillary or terminal panicles, small, white, fragrant, urceolate, 5-merous; calyx pubescent (ciliate); ovary 2–5-celled with 1 ovule in each cell; style very short, persistent; stamens 10, free, inserted in 2 series on the disk: frs. small, with a fleshy pulp in which are imbedded the large rounded seeds; cotyledons epigeous in germination; first foliage-lvs. simple, opposite.—Several species are known, occurring in India and Ceylon and extending to Austral., the Philippines, and China. Only one has as yet been intro. into cult. in this country.

pentaphýlla, DC. (*Limònia pentaphýlla,* Retz. *Toluifera cochinchinénsis,* Lour. *G. cochinchinénsis,* Pierre). Small inermous shrubs with pinnate lvs. having 1–7 lfts.: fls. urceolate, very small, white, fragrant: berry 2–3-celled with 1 or 2 brownish green rounded seeds imbedded in the fleshy pulp.—A very variable species common throughout India, Indo-China, Philippine Isls. and Malayan Archipelago. Ill. Roxbg. Pl. Coromandel, 1:60, pl. 84. Talbot, For. Fl. Bombay, p. 192, fig. 117.—This species is sometimes grown as an ornamental in greenhouses or out-of-doors in the southern states. Because of its dark green glossy lvs. and translucent pinkish berries, it is a handsome shrub for warm semi-tropical climates. Walter T. Swingle.

GLYCYRRHÌZA (Greek, *sweet root*). *Leguminòsæ.* Licorice, also spelled Liquorice, and Lickorice. This genus contains the plant whose roots produce the licorice of commerce.

The genus has about a dozen widely scattered species of perennial herbs, often glandular: lvs. odd-pinnate; lfts. of indefinite number, rarely 3, entire, with minute glands or teeth: fls. blue, violet, white or yellowish, in axillary racemes or spikes, which are peduncled or sessile.—About a dozen species in the Medit. region, Trop. Asia, W. Amer. and S. Amer., only one of which appears to be cult.

The roots of *Glycyrrhiza glabra,* of southern Europe and central Asia, are used extensively by druggists; in America by brewers and manufacturers of plug tobacco; in Turkey, Egypt and France to make cooling drinks. Our supply—more than $1,500,000 worth in 1899—is derived mainly from Spain, Portugal, Italy, Turkey and Russia (Transcaucasia), the roots from Spain and Italy being considered best, and those from Turkey poorest on account of their bitterness. The soil for licorice must be deep, mellow, moist, rich and free from stones. Plants are usually set in rows, 3 feet or more apart, and not less than 1 foot asunder. After the plants have covered the ground, they are allowed to shift for themselves for three or four years. Harvesting is primitive, the roots being exposed by the plow and pulled by hand. Large quantities of roots are thus left to produce a succeeding crop or to overrun the field as weeds. One ton to the acre is considered a fair yield; 1.6 cents a pound an average price. In America the only fields worthy the name are in California, where licorice is not considered very paying. Experiment and experience with it are, however, but little more than begun. (M. G. Kains.)

glàbra, Linn. Height 2–3 ft.: lfts. ovate, subretuse, subglutinous beneath, 4–8 pairs, with an odd one: spikes peduncled, shorter than the lvs.; fls. closely clustered, the calyx glandular pubescent: pods glabrous, 3–4-seeded. Summer and autumn.—Seeds in pods are listed by a few dealers with miscellaneous agricultural seeds. Wilhelm Miller.

GLYPTOSTRÒBUS (*engraved* or *marked cone*). *Pinàceæ.* One or 2 species of trees of swamps and low grounds in China, separated by some authors from Taxodium, but here included in that genus. The basis of separation from Taxodium lies mostly in the fact that the cone-scales are deciduous, whereas in Taxodium proper they are persistent; the mature cones are obovoid with a long contracted base, the seeds scarcely angled and stipitate or narrowed at the base into a wing. *G. heterophýllus,* Endl. (*Taxòdium heterophýllum,* Brongn., which see), is a shrub to 10 ft. high, with lower branches pendulous: lvs. long, linear, 3-rowed or scattered, on the fruiting branches short and rather obtuse and spirally imbricate: cones ovoid, ¾in. long: tender, and little cult.

GMELÌNA (after one of five distinguished German botanists named Gmelin). *Verbenàceæ.* Trees and shrubs, bearing yellow or brownish irregular flowers sometimes nearly 2 inches across. A very few plants may be cultivated in European warmhouses, and in America only in southern Florida and southern California outdoors.

Spiny or not: shoots tomentose: lvs. opposite, entire, toothed or lobed: fls. in panicled cymes or racemes, tomentose at least while young; calyx bell-shaped, shortly 5-toothed or entire; corolla-tube slender below; limb oblique, 5- or 4-lobed; stamens 4, didynamous, nearly exserted: fr. a succulent drupe.—Eight or 10 species from E. Asia and N. Austral. The genus produces a fancy timber similar to teak, which is a product of the same order. Vitex and Clerodendron are better known congeners.

A. *Plant not climbing.*

B. *Lvs. becoming 9 in. long, 6 in. wide.*

arbòrea, Roxbg. (*G. Rheèdii,* Hook.). Unarmed tree, sometimes attaining 60 ft., deciduous, flowering with the young lvs.: lvs. cordate-ovate, entire: panicles often 1 ft. long, terminal. India, Malaya. B.M. 4395.—Cult. apparently only in S. Calif. by Franceschi, who keeps *G. Rheedii* separate.

BB. *Lvs. ½–1½ in. long.*

asiática, Linn. (*G. parviflòra,* Pers., a typographical error for *G. parvifòlia,* Roxbg.). Shrubby, sometimes spinescent: lvs. ovate or obovate, entire or lobed: fls. in racemose clusters, the corolla about 1½ in. across. India, Ceylon.

AA. *Plant scandent.*

Hýstrix, Kurz. A large spiny scandent shrub: lvs. 3 x 1½ in., entire, glaucous beneath: fls. in dense terminal cymes, the bracts very large and nervose, colored; corolla about 2 in. across, yellow, but not hairy on the outside as in *G. asiatica.* E. Indies.—A sprawling plant with the habit of bougainvillea.

N. Taylor.†

GNAPHÀLIUM. See *Leontopodium* and *Helichrysum.* There are various native gnaphaliums, but they are not in cultivation. *G. lanatum* of gardeners is *Helichrysum petiolatum.*

GNÌDIA (*Gnidus,* a place in Crete). *Thymelæàceæ.* Trees, shrubs or subshrubs, of about 100 species in Trop. and S. Afr. and E. India. Some of them have been grown abroad as greenhouse evergreen woody often heath-like subjects: lvs. mostly small: fls. white, yellow, red or violet, mostly in heads on the ends of the branches; perianth-tube cylindrical, at length detaching above the ovary, the lobes 4 and spreading, with scales in the throat alternating with the lobes; stamens 8; ovary sessile, 1-celled: fr. small and dry, included in the persistent base of the perianth. *G. polystàchya,* Berg. Handsome shrub, to 6 ft., with many graceful pubescent branches: lvs. crowded-imbricate: fls. small, yellow, in terminal heads. S. Afr. B.M. 8001. G.C. III. 41:294. *G. tomentòsa,* Linn. Three to 4 ft.: lvs. ovate or ovate-lanceolate, decussate and sometimes reflexed: fls. yellow, fascicled with the lvs. at the ends of the branches, the tube slender and silky. S. Afr. B.M. 2761.

L. H. B.

GOAT'S-BEARD is usually *Aruncus sylvester* (*Spiræa Aruncus*); also the genus Tragopogon.

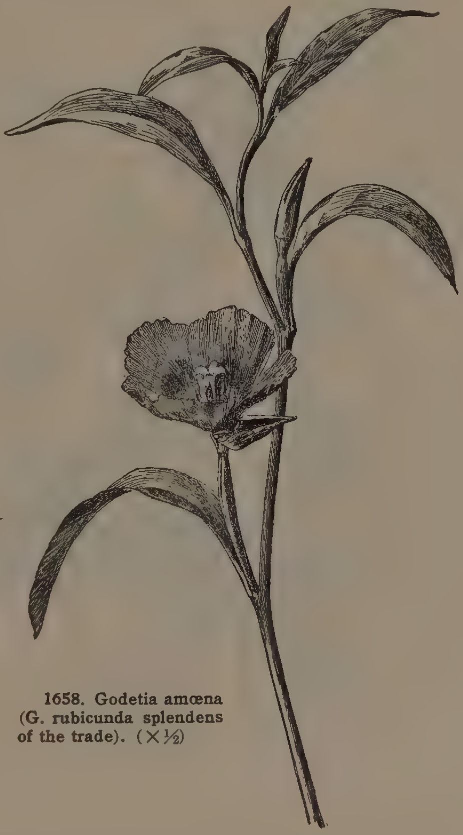
GODÈTIA (C. H. Godet, Swiss botanist). *Onagràceæ.* Mostly erect annuals with very showy flowers in leafy racemes or spikes.

Calyx-tube obconic or funnelform; petals rose, lilac-purple or white, often marked with a large deep crimson or purple spot; stamens 8; ovary 4-celled, inferior: fr. a many-seeded caps.—Twenty or more species in the western parts of S. and N. Amer., especially Calif.

Seed may be surface-sown in the late fall in order to be covered by the rains which follow, or in February lightly covered in sunny or in half-shady places. *G. amœna* is very popular and furnishes an abundance of bloom in early summer when many late spring annuals have succumbed to advancing heat. In the wild garden the species come again freely but have a tendency to move to new ground after the second year.

A. *Plants tall, slender: fls. loosely spicate-paniculate.*

amœna, Lilja. Farewell-to-Spring. Fig. 1658. Slender, branching, 1–2 ft. high: lvs. linear to lanceolate, ½–2½ in. long, often with smaller ones fascicled in the axils: buds erect: calyx-lobes united and turned to one side on expansion of the fl.; corolla lilac-crimson or red-pink, satiny, 1–2 in. broad: caps. teretish, sessile or very shortly pedicelled. Cult. also in European gardens (since 1818). Exhibits considerable variability, especially in the size, and color-scheme of the fls. *G. rubicúnda,* Lindl. (B.R. 1856), is the lilac-crimson form. *G. vinòsa,* Lindl. (B.R. 1880), is a white-fld. state. *G. Schwáminii* (Gn. 70:203), a double-fld. pink form. *Œnothèra Líndleyi,* Douglas (B.M. 2832), has the crimson petals with a large central blotch of deeper color. *Œnothèra róseo-álba,* Bernh. (Reichenbach, Icon. Bot. Exot., pls. 47 and 150), is a prolific-flowering form.



1658. Godetia amœna (G. rubicunda splendens of the trade). (×½)

Bóttæ, Spach. Similar to *G. amœna:* buds nodding: petals pink or light crimson; stigmas united at base to form a cup-like apex to the style: caps. long-stalked, usually with flat sides. S. Calif. near the coast.

AA. *Plants low: fls. in a short spike or cluster of spikelets.*

grandiflòra, Lindl. (*Œnothèra Whítneyi,* Gray). Fig. 1659. Stout, simple and dwarfish, 4–12 in. high: lvs. oblong, tapering to base and apex: buds large, 1–2 in. long; corolla 3–5 in. across, rose-red with a deeper blush or blotch in center, varying into pure white (Duchess of Albany), dark crimson (Lady Albemarle) or bright carmine (Lady Satin Rose): caps. sessile, 4-

sided, 8-ribbed. B.M. 5867. J.F. 318.—A highly prized species.

G. decúmbens, Douglas. Sts. ascending, strongly flattened, whitish pubescent: ovary white-woolly. B.M. 2889. B.R. 1221. —Not certainly known in a wild state. Seed originally from Ore. Differs little technically from G. quadrivulnera or its forms but is quite unchanged in its characters after 75 years or more of cult. in European gardens. It is an excellent illustration of the manner in which many strains of the smaller-fld. godetias maintain their slight but distinctive characters, although subject for many years to the varying conditions of garden cult.—*G. magellánica*, Burbank, a diffuse free-flowering species with lavender fls. the size of G. amœna, has been recently intro. from Patagonia by Luther Burbank.—*G. quadrivúlnera*, Spach. Erect, slender, pubescent: lvs. obovate to linear or the uppermost lanceolate and half-conduplicate: petals lilac or pale crimson, usually with a spot at apex, 4–6 lines long: caps. sessile, 4-sided, lightly 8-ribbed. B.R. 1119. Occasionally cult., but probably not in the trade.—*G. Romanzòvii*, Spach, from the "northwest coast," not now known in a wild state, has been cult. in Eu. nearly a century. Very leafy with young parts white-pubescent: lvs. oblong-oblanceolate. B.R. 562.

W. L. Jepson.

1659. Godetia grandiflora, Œnothera Whitneyi of the trade. (×⅓)

GOÈTHEA (Goethe, the great German poet, who was also a botanist). *Malvàceæ.* Two Brazilian evergreen shrubs, seldom grown in hothouses. Lvs. alternate, simple, entire or nearly so: fls. showy, in cymes from the leafless sts. or sometimes solitary in the axils, subtended by large cordate red showy calyx-like bracts; calyx 5-toothed, included within the bracts; petals short; stamens united in a column, which is 5-toothed below the apex; ovary 5-celled, each 1-ovuled. *G. strictiflòra*, Hook. (*G. cauliflòra*, Hort.), is a small shrub or bush with large ovate lvs. sinuate on upper half, and aggregated fls. in yellowish white red-tinged bracts; petals small, obcordate, veiny; calyx whitish or greenish, the lobes ovate-acuminate; fls. on short-peduncles that are aggregated in the axils along the st. B.M. 4677. J.F. 4:365. *G. multiflora*, Nichols., and *G. semperflorens*, Nees & Mart., belong in Pavonia.

L. H. B.

GOLDEN CHAIN: *Laburnum vulgare.*

GOLDEN FEATHER: *Chrysanthemum Parthenium.*

GOLDENROD: *Solidago.*

GOLDEN SEAL: *Hydrastis.*

GOLDFÙSSIA: *Strobilanthes.*

GOLD THREAD: *Coptis trifolia.*

GOMBO, Gumbo, or Okra: *Hibiscus esculentus.*

GOMÈSA (named in honor of Bernardinus Antonius Gomes). *Orchidàceæ.* Stove epiphytes.

Pseudobulbs 1- or 2-lvd.: racemes often many-fld., lateral; sepals free and spreading, or the lateral approximate or connate; petals equaling or wider than dorsal sepal; lip affixed to base of column, continuous, spurless, the lateral lobes small; pollinia 2.—About 5 or 6 species, natives of Brazil.

planifòlia, Klotzsch (*Odontoglóssum planifòlium*, Reichb.). Pseudobulbs ovoid, 1½–2 in. long, 2-lvd.: lvs. 4–5 in. long: racemes exceeding the lvs.; fls. fragrant, light greenish yellow; sepals and petals oblong, acute, the lateral sepals united nearly to the apex; lip shorter than petals, broadly oblong, acute, reflexed. B.M. 3504 (as Rodriguezia). G.W. 14, p. 517.

G. Binòtii, Hort. Racemes 15–30-fld.; fls. small, orange, with a white column. Brazil.—*G. Glaziòvii*, Cogn. Climbing: st. elongated: pseudobulbs 2–4 in. apart: fls. light green. Brazil.

George V. Nash.

GÓMPHIA: *Ouratea.*

GOMPHOCÁRPUS (*club-fruit*). *Asclepiadàceæ.* Perennial herbs, or subshrubs, of more than 100 species, mostly of the Old World, of which one has been mentioned recently in horticultural literature abroad; very closely allied to Asclepias, being distinguished mostly by the absence of crests or appendages on the hoods. *G. téxtilis*, Naudin, a warm-country species but nativity unknown, is a semi-woody plant 3 ft. high with slender branches: lvs. opposite, linear-lanceolate: fls. white, in terminal clusters, the lobes of the crown violet: fr. large, obliquely oval in outline, bladdery, pale green, long-hairy, to 4 in. long. R.H. 1902, p. 35. —Described as a showy and worthy plant for the border.

L. H. B.

GOMPHOLÒBIUM (name refers to club-shaped pod). *Leguminòsæ.* Two dozen Australian yellow- or red-fld. shrubs, rarely cult. Lvs. simple or compound, the lfts. mostly narrow: fls. papilionaceous, solitary, few or in short racemes; standard orbicular or reniform, exceeding the other petals; wings falcate-oblong; keel mostly broader than the wings, obtuse; stamens free: pod very wide or nearly globular, inflated, bearing small seeds. They are said to be excellent greenhouse shrubs; prop. by cuttings of young shoots. *G. polymórphum*, R. Br. Glabrous shrub or undershrub, variable in foliage and habit: lfts. 3, but sometimes 5 or 7 or 9, digitate, mostly linear, to 1 in. long: fls. orange-yellow to bright crimson: pod much inflated, ovoid-globular. B.M. 1533, 4179. H.U. 1, p. 166. B.R. 1574 (as *G. venulosum*, Lindl.). B.R. 1615 (as *G. tenue*, Lindl.). B.R. 25:43 (as *G. versicolor*, Lindl.).

L. H. B.

GOMPHRÈNA (name suggested by *Gromphræna*, Pliny's name for some amaranth, supposed to be derived from *grapho*, to write or paint; alluding to the highly colored or "painted" foliage). *Amarantàceæ.* Herbaceous plants grown as "everlastings."

Herbs erect or prostrate, pubescent to villous, with or without a leafy involucre: fls. short or long, white or colored: bracts short or long, concave, and keeled, winged or crested on the back.—About 70 species, mostly in the warmer parts of Amer. and Austral., but the globe amaranth is widely dispersed throughout the tropics. For cult., see *Annuals* and *Everlastings.*

This genus includes the globe amaranth, a common everlasting flower of easy culture. It is also known as bachelor's button, though two other utterly distinct plants (*Centaurea Cyanus* and *Ranunculus acris*) have the same popular name. The flower-heads are an inch or less in diameter, globose, of many colors, and chiefly remarkable for the showy bracts, which hide the true flowers. In a family remarkable for brilliant foliage this genus seems to be the only one valued for everlastings. Nearly all the other everlasting flowers of importance belong to the Compositæ.

globòsa, Linn. GLOBE AMARANTH. BACHELOR'S BUTTON. Height 18 in. or less: lvs. elliptic to obovate, the largest 4 in. long, 1½ in. wide, tapering to a petiole. July. B.M. 2815. R.H. 1890, p. 522. F.R. 1:333. The following names of horticultural varieties indicate the range of color: vars. **álba, aùrea, cárnea, nàna compácta** (=*alba*) **purpùrea, striàta, violàcea.** Dwarf and compact forms are likely to be associated with any color. There is a narrow-lvd. form of this species which Voss calls **G. Haageàna,** Klotzsch (*G. aurantìaca*, Hort. *G coccínea*, Decne.), which has lanceolate lvs., often 6 times as long as broad. The lvs. are rarely ½ in. wide. R.H. 1854:161. All are easily grown annuals.

G. gnaphalioìdes, Vahl=Pfaffia.

WILHELM MILLER.

GONGÒRA (after Don Antonio Caballero y Gongora, Bishop of Cordova). Includes *Acropèra. Orchidàceæ*, tribe *Vándeæ*, subtribe *Cyrtopòdieæ*. A small group of plants with curious spotted flowers, not common in cultivation, and of little value except for collections.

Distinguished from the other members of the subtribe by being epiphytic, having the dorsal sepal adnate to the column, and by its many-fld. raceme: dorsal sepal erect, spreading, thus appearing to spring from the base of the column; lateral sepals spreading or reflexed from the base of the column, wider; petals small, adnate to the base of the column; labellum continuous with the column, narrow and fleshy, with 2 thick lateral horned or aristulate lobes, and a central one which is saccate or even folded, forming a vertical plate; column erect or ascending, not winged: pseudobulbs sulcate, sheathed, bearing 1 or 2 large, plicate lvs.: fls. borne in a long, loose, pendent raceme arising from the base of the pseudobulbs.—Over 20 species from Brazil to Mex.

Gongoras are extremely free-flowering, and grow easily in a mixture of sphagnum and peat, with a little charcoal added for drainage. During the growing season they require plenty of water, and brisk heat. In the winter they require little water, but should be kept in a moist atmosphere in a cool, shaded house. They grow well with cattleyas, or in a temperature of 60° in winter and 80° in summer. Some growers prefer to use fine fern root packed tightly and for a top finish a little fine moss found in damp meadows, instead of sphagnum, which in this climate is quick to decay. (Wm. Mathews.)

A. *Lateral sepals ovate or oblong, truncate.*

truncàta, Lindl. Pseudobulbs deeply furcate: lateral sepals rotund, oblong, truncate, the upper one ovate, keeled; petals minute, ovate; sepals and petals pale straw-color, spotted with purple; base of labellum compressed in the middle, 2-horned; apex ovate, canaliculate. B.R. 31:56.

AA. *Lateral sepals broad, ovate, pointed.*

B. *Fls. light sepia-brown; ovary much incurved.*

galeàta, Reichb. f. (*Maxillària galeàta*, Lindl. *Acropèra Lóddigesii*, Lindl.). Fig. 1660. Pseudobulbs ovate-conical, clothed with membranous scales: lvs. broadly lanceolate, 6 in. long: racemes drooping, 6–8 in. long, with 6–12 pale sepia-brown fls.; dorsal sepal galeate; petals small, oblong-truncate; labellum 3-lobed; lateral lobes inflexed, middle one saccate. The plants bear several short, rather large-fld. racemes. Aug. Mex. B.M. 3563. L.B.C. 17:1645.

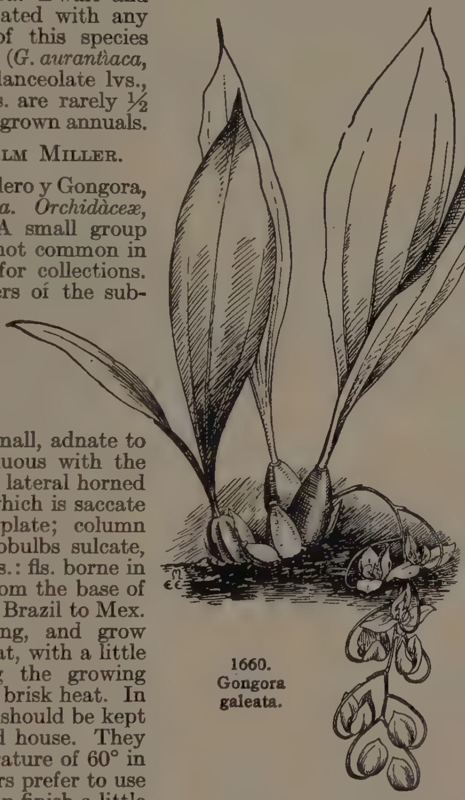
BB. *Fls. yellow; ovary somewhat incurved.*

armenìaca, Reichb. f. (*Acropèra armenìaca*, Lindl.). Pseudobulbs ovate, sulcate, 2-lvd.: raceme loose, bearing many yellow fls.; sepals ovate, rounded, apiculate, the lateral ones oblique; petals one-half as long as the column; labellum fleshy; apex ovate, plane, acuminate, base tuberculate, crested. B.M. 5501.

AAA. *Lateral sepals lanceolate to ovate-lanceolate.*

B. *Fls. chocolate-brown, spotted.*

atropurpùrea, Hook. Pseudobulbs oblong-cylindrical, deeply sulcate, 2-lvd.: lvs. about 1 ft. long, lanceolate, subplicate: racemes numerous, 2 ft. long, bearing many chocolate-colored, spotted fls. about 2 in. diam.; margins of the sepals revolute; petals small, twisted at the apex; labellum 4-horned at the base; apex folded so as to form a vertical triangular plate. Trinidad. B.M. 3220.—This species is the most common in cult. It is nearly always in flower during the summer.



1660. Gongora galeata.

BB. *Fls. yellow, spotted.*

quinquenérvis, Ruiz & Pav. (*G. maculàta*, Lindl.). Pseudobulbs ovate-oblong, deeply furrowed, 2-lvd.: lvs. broadly lanceolate, 5-plaited: racemes many, 2 ft. long, with numerous yellow fls. spotted with dark red; lateral sepals reflexed, meeting in the back; petals small, linear-oblong, from the middle of the column; lip 4-horned at base; apex folded, tapering to a setaceous point. May–Aug. B.M. 3687. B.R. 1616.—A curious plant, much resembling *G. atropurpurea* except in color and form of fls.

BBB. *Fls. dull red-purple spotted, with a yellow labellum.*

trícolor, Reichb. f. (*G. maculàta* var. *trícolor*, Lindl.). Pseudobulbs ovoid, 2½ in. long, deeply furrowed: lvs. ovate-oblong, acuminate, about 5-ribbed, 6 in. long: raceme slender, pendulous, lax-fld., 6–10 in. long; pedicels with ovary 1½–2 in. long, speckled like the rachis; fls. about 2 in. long; dorsal sepals lanceolate, with revolute margins, tip recurved, lateral sepals ovate-lanceolate, with revolute margins, dull red-purple, with a pale, stout midrib; free portion of the petal spreading, upcurved, lanceolate, speckled; labellum golden yellow, base cuneiform saccate, truncate in front, with an awn on each side, apical part broadly funnel-shaped, with a spurlike, slender, speckled tip, gibbous behind; column slender, speckled. B.M. 7530. B.R. 33:69.

G. Beyrodtiàna, Schlecht. Allied to G. truncata. Infl. pendulous, about 16 in. long; fls. pale yellow, spotted with purple. Colombia.—*G. bufònia*, Lindl. Resembles G. atropurpurea in habit, lvs. and pseudobulbs: fls. yellowish white, thickly spotted with dull purple. Brazil. B.R. 27:2. G.W. 13, p. 110.—*G. fuscàta*, Hort. (Acropera fuscata and luteola, Hort.), has been cult. for many years, but no description is available.—*G. Tracyàna*, Rolfe. Sepals and petals greenish yellow, marked with brown; lip ivory-white. Peru.

H. Hasselbring.

GONIÒMA (Greek, *gonia*, angle, corner; the corona cornered near the top). *Apocynàceæ.* Shrub, introduced for the warmer parts of the country.

A monotypic genus containing a S. African glabrous plant with coriaceous lvs. and terminal corymbose fls.: calyx small, with 5 more or less herbaceous sepals; corolla with 5 lobes, overlapping to the left; stamens inserted at the middle of the corolla-tube. Gonioma differs from Tabernæmontana in having the ovules arranged in 2 series instead of an indefinite number of series.

Kamássi, Mey. (*Tabernæmontàna Camássi*, Regel). Height 16–20 ft.: lvs. opposite or the upper ones in 3's, oblong-lanceolate, entire, leathery, 4–6 lines wide: corymbs small, terminal, 8–10-fld.; fls. salver-shaped, yellowish, 3 lines long; tube a little wider at the middle and angled, constricted at top, pilose within from the middle to the top; lobes a third as long as the tube, ovate, cordate, twisted to the right in the bud; style 2-cut: fr. 1–2½ lines long.—Yields the hard yellow Kamassi wood of S. Afr.

N. Taylor.†

GONIOPHLÈBIUM. A subgenus of Polypodium, (or perhaps a distinct genus), with a special type of anastomosing veins. For *G. subauriculatum* and *G. vacciniæfolium*, see *Polypodium.*

GONIÓPTERIS (Greek, *angled fern*). *Polypodiàceæ.* A generic name for a group of tropical ferns belonging with Dryopteris, with naked rounded sori and the lower veinlets of contiguous segments or lobes united. Has been placed under Polypodium. For *G. crenata*, see *Dryopteris crenata.*

GONIOSCỲPHA (name refers to the *angled perianth*). *Liliàceæ.* One species, *G. eucomoìdes*, Baker, an odd nearly stemless plant from the E. Himalayas, producing 1 thick dense short-peduncled spike 3–5 in. long, of small lurid green fls.: lvs. few in a rosette, 10–15 in. long, 5–6 in. broad, elliptic or elliptic-oblong, several-nerved; petiole 3–4 in. long, broad: perianth open, somewhat fleshy; anthers 6, sessile; stigma somewhat 3-lobed: fr. a 1-seeded globose-ellipsoid dark brown berry, becoming dry. B.M. 8078. G.C. III. 20:748. G.W. 12:750.—Blooms in late autumn; produces a short fleshy rootstock.

L. H. B.

GONÓLOBUS (name refers to the *angled pod* of one of the original species). *Asclepiadàceæ.* Mostly trailing or climbing plants, herbaceous or woody, of Amer., chiefly tropical: lvs. opposite and mostly cordate: fls. dull or dark-colored, of medium or large size, in fascicles or umbel-like cymes; corolla rotate to campanulate, 5-lobed; crown ring-like or cup-like, entire, lobed or divided; anthers short and borne under the disk of the stigma or on the margin of it; pollinia nearly or quite horizontal; stigma flat-topped.—Seventy-five or more species, only one of which seems to be in horticultural lists. **G. edùlis,** Hemsl., of Guatemala and Costa Rica, is a more or less rusty-hairy twining shrub, with ovate-oblong deeply cordate lvs., and 3–5-fld. short peduncles: corolla of medium size, white, densely bearded inside; crown short, with 5 interior longitudinal lamellæ: follicles the size of a swan's egg, edible.—It is said to be hardy at Santa Barbara and to bloom profusely but to set no fr. It is the guayote of the natives of Costa Rica.

G. Cundurángo, Triana=Marsdenia.—*G. Martiànus*, Hook., is properly Fischeria Martiana, Dcne. A handsome stove twiner with pretty fls. in early summer: lvs. oblong-ovate, hairy, acuminate: fls. white with a green ring at base and a red hairy calyx Brazil. B.M. 4472. J.F. 1:33.

L. H. B.

GOOBER is a commoner name in the South than "peanut," which is the universal name in the North. For culture, see *Peanut;* for botany, see *Arachis.*

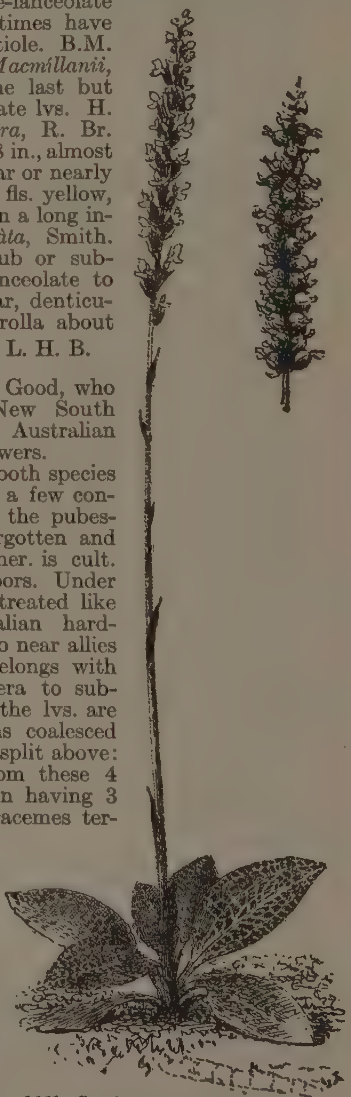
GOODÈNIA (Bishop Samuel Goodenough, England, 1743–1827, who wrote on Carex). *Goodeniàceæ* (sometimes written *Goodenovieæ*). The family Goodeniaceæ is allied to the Campanulaceæ, differing in never having milky juice, the style surrounded by an indusium or cup-shaped or two-lipped expansion, the cells of the ovary mostly more in number, and other technical characters. There are a dozen genera of herbs and shrubs and probably 300 species, mostly Australian. Probably none of them is in regular cultivation, although Goodenia and Scævola are sometimes mentioned in horticultural literature.

About 100 species of Goodenia occur in Australia: calyx-tube adnate to the ovary, the lobes free or adnate at the base; style undivided: caps. with 2 or rarely 4 valves: herbs, subshrubs, or shrubs, with yellow, purplish or blue fls. The species most likely to be met with in horticultural literature are: *G. grandiflòra*, Sims. Erect herb, with large yellow fls. more or less streaked purple, linear calyx-lobes, and broadly ovate or ovate-lanceolate toothed lvs. that sometimes have small lobes along the petiole. B.M. 890. B.R. 31:29. *G. Macmíllanii*, F. Muell., very like the last but with purple fls. and lyrate lvs. H. F.II. 4:240. *G. stelligera*, R. Br. Perennial herb: st. 12–18 in., almost leafless: radical lvs. linear or nearly so, entire, 3–6 in. long: fls. yellow, nearly or quite sessile, in a long interrupted spike. *G. ovàta*, Smith. Glabrous or viscid shrub or subshrub, to 4 ft.: lvs. lanceolate to ovate or nearly orbicular, denticulate: fls. yellow, the corolla about ½in. long.

L. H. B.

GOÒDIA (after Peter Good, who found the plant in New South Wales). *Leguminòsæ.* Australian shrubs, with pea-like flowers.

There are 2 goodias; both species have long been cult. in a few conservatories abroad, but the pubescent species is now forgotten and the glabrous one, in Amer. is cult. chiefly in S. Calif. outdoors. Under glass these shrubs are treated like Cape heaths or Australian hard-wooded plants. It has no near allies of garden value. It belongs with 4 other Australian genera to subtribe Bossiæa, in which the lvs. are mostly simple: stamens coalesced into a sheath, which is split above: seeds strophiolate. From these 4 genera Goodia differs in having 3 pinnate lfts. and its racemes terminal or opposite the lvs. instead of axillary. A. Schultheis writes that goodias are occasionally seen in florists' windows in America. Wm. Watson, of Kew, says the flowers are very fragrant, and remain on the plant a long time. He adds (G.F. 2:244): "Probably this plant, if taken



1661. Goodyera pubescens. (×½)

in hand by the florists, would prove quite as useful for spring flowering as the popular *Cytisus racemosus*."

lotifòlia, Salisb. Often misspelled "latifolia," but the name means "lotus-leaved." A tall much-branched glabrous shrub: lfts. ovate or obovate, very blunt, about ¾in. long: racemes loose, many-fld.; the fls. yellow with purple markings near the base. B.M. 958. J.H. III. 29:484. H.F. II. 6:358.—Likely to be confused with *Argyrolobium Andrewsianum*, belonging to the Crotalaria subtribe, in which the seeds are not strophiolate. In Argyrolobium the 3 lfts. are digitate and the stipules, bracts and bractlets small but persistent. *A. Andrewsianum* has sparsely silky lvs. In Goodia the stipules, bracts and bractlets are very evanescent.

Wilhelm Miller.
N. Taylor.†

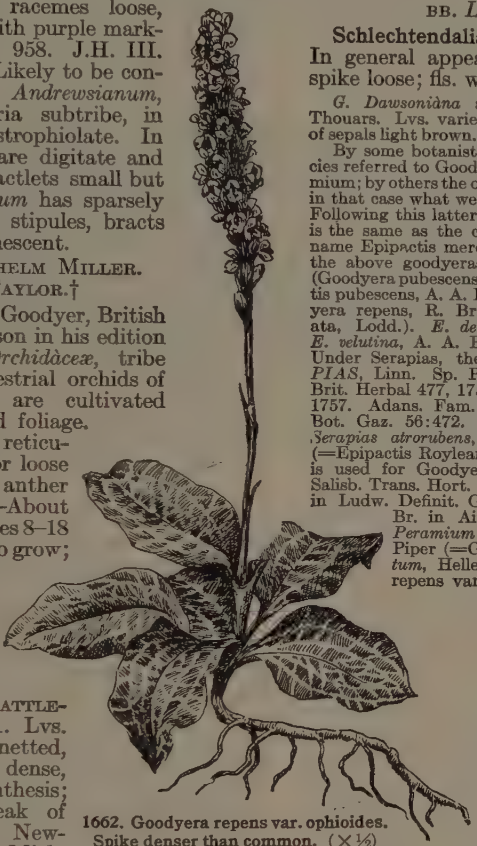
GOODYÈRA (after John Goodyer, British botanist, who helped Johnson in his edition of Gerarde's Herbal). *Orchidàceæ*, tribe *Polychóndreæ*. Dwarf terrestrial orchids of minor importance which are cultivated chiefly for their variegated foliage.

Leaves radical, usually reticulately veined: fls. in dense or loose spikes; labellum saccate; anther on the back of the column.—About 25 species. They have scapes 8–18 in. high at most. Difficult to grow; require shade. Includes the rattlesnake plantain.

A. *Plants hardy natives.*

B. *Labellum strongly inflated, with a short tip.*

pubéscens, R. Br. Rattlesnake Plantain. Fig. 1661. Lvs. ovate, deep green; veins netted, white: scape stout; spike dense, ovate in outline before anthesis; fls. globular, whitish; beak of stigma short, obscure. Aug. Newfoundland to Fla., west to Mich. and Minn. L.B.C. 1:1. B.B. 1:474. Mn. 2:54. F.S. 15:1555. A.G. 12:281; 13:520. C.L.A. 4:108. Gn.M. 4:15.—Should be grown in ordinary loam mixed with pine needles and dry pine twigs. Not well suited for greenhouse cult.



1662. Goodyera repens var. ophioides. Spike denser than common. (×½)

BB. *Labellum saccate, with an elongated tip.*

C. *Beak of the stigma shorter than its body.*

rèpens, R. Br. Lvs. ovate to oblong-lanceolate; veins dark: spike 1-sided; labellum with a recurved tip. L.B.C. 20:1987. Eu. Var. **ophioìdes,** Fern. (Fig. 1662), is the American form of this species, with very broadly marked lvs.

CC. *Beak as long as or longer than the stigma.*

tesselàta, Lodd. (*G. pubéscens* var. *mìnor*). Lvs. broadly ovate to oblong-lanceolate; venation exceedingly variable: scape slender; spike loose; fls. white; labellum less saccate than in *G. repens;* tip straight. N. U. S. and Canada. B.M. 2540. L.B.C. 10:952.—Confused by tradesmen with the next. Should be planted out in a rockery in shade, the roots being firmly placed among dead pine needles and loam.

BBB. *Labellum scarcely saccate, margin involute.*

Ménziesii, Lindl. Plant rather large, the st. sometimes 18 in. high, being taller than *G. tesselata:* lvs. ovate-lanceolate, dark green; veins netted: spike somewhat 1-sided, rather densely fld. W. U. S. to N. New England.—Advertised by Dutch dealers.

AA. *Plants tender exotics, cult. under glass.*

B. *Lvs. with a whitish midvein.*

velùtina, Maxim. Fls. whitish, tinged rose: lvs. ovate, velvety, purplish green, with white rib. Japan. F.S. 17:1779.

BB. *Lvs. with white, netted veins.*

Schlechtendaliàna, Reichb. f. (*G. japónica,* Blume). In general appearance like *G. tesselata.* Lvs. ovate: spike loose; fls. white. Japan.

G. Dawsoniàna and *G. díscolor.* See Hæmaria.—*G. nùda,* Thouars. Lvs. variegated: fls. whitish, with petals and midveins of sepals light brown. Mascarene Isls.—*G. quercícola.* See Physurus.

By some botanists, the name Goodyera is given up. The species referred to Goodyera are then by some authors placed in Peramium; by others the old application of the name Epipactis is used, and in that case what we have been calling Epipactis goes in Serapias. Following this latter disposition, the characterization of Epipactis is the same as the characterization given here for Goodyera, the name Epipactis merely supplanting Goodyera.—Under Epipactis, the above goodyeras take names as follows: *E. Willdenovii,* House (Goodyera pubescens, R. Br., Peramium pubescens, MacM., Epipactis pubescens, A. A. Eaton, not Pursh). *E. repens,* Crantz (Goodyera repens, R. Br.) *E. tesselata,* A. A. Eaton (Goodyera tesselata, Lodd.). *E. decipiens,* Ames (Goodyera Menziesii, Lindl.). *E. velutina,* A. A. Eaton. *E. Schlechtendaliana,* A. A. Eaton.—Under Serapias, the following synonyny would occur: *SERAPIAS,* Linn. Sp. Pl. 949, 1753. *Helleborine,* (Tourn.) J. Hill., Brit. Herbal 477, 1756. *Epipactis,* Zinn, Cat. Pl. Hort. Goett. 85, 1757. Adans. Fam. 2:70. 1763. *Amesia,* Nelson & MacBride. Bot. Gaz. 56:472. 1913. Species: *Serapias Helleborine,* Linn.; *Serapias atrorubens,* Hoffm. *Serapias gigantea,* A. A. Eaton (=Epipactis Royleana, Lindl.), and several others.—If Peramium is used for Goodyera, the synonymy becomes: *PERAMIUM,* Salisb. Trans. Hort. Soc. 1:301. 1812. *Epipactis,* (Haller) Boehm. in Ludw. Definit. Gen. Pl. 1760. Not Zinn 1757. *Goodyera,* R. Br. in Ait. Hort. Kew, ed. 2, 5:197, 1813. Species: *Peramium pubescens,* MacM.; *Peramium decipiens,* Piper (=Goodyera Menziesii, Lindl.); *Peramium tesselatum,* Heller; *Peramium ophioides,* Rydberg (=Goodyera repens var. ophioides Fernald).

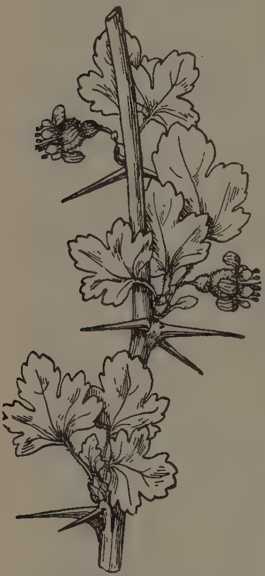
Oakes Ames.
L. H. B.†

GOOSEBERRY. A bush-fruit, grown for its large berries, which are mostly consumed green in cookery.

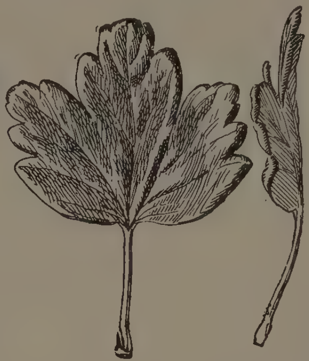
The gooseberry has received comparatively little attention in America, although in northern Europe, and especially in the British Isles, it has long been a prime favorite, and a great improvement has taken place in its size there during the last 200 or 300 years. When it was first cultivated in Europe—probably in the sixteenth century—the wild fruit, if it was like what it is now, would be only about ½ inch in diameter and less than one quarter of an ounce each in weight. The largest gooseberries which have been produced in recent years average several times this size, the largest one of which there is a record weighing two ounces, although there are doubtless larger specimens produced. The English and European gooseberries are derived from a species native of northern Europe, *Ribes Grossularia* (Figs. 1663, 1664). The varieties of *Ribes Grossularia* do not succeed well in America as a general rule, although in some places they do well. The chief obstacle to their successful culture is the gooseberry mildew, which it has been found very difficult to control.

As late as 1846 no cultivated varieties of American species of gooseberries were mentioned by writers, an early reference, according to Bailey, being in 1849 in the "Northern Fruit Culturist," by Goodrich, where the author writes: "We have it from good authority that native sorts have been discovered both in New Hampshire and Vermont well adapted to garden culture." In 1847 the Houghton's Seedling was exhibited at a meeting of the Massachusetts Horticultural Society, this being the first improved form of the native gooseberry of which there is a record. This variety was originated or found by Abel Houghton, Jr., Lynn, Massachusetts. It is probably a seedling of the native species, *Ribes hirtellum* (Figs. 1665, 1666, 1667). The first improvement on the Houghton was the Downing (Fig.

1668), a seedling of the Houghton, which was originated by Charles Downing, Newburgh, New York, and first brought into notice in 1853. It is thought by some authorities to have been a hybrid between Houghton and *Ribes Grossularia,* the European species. The Downing is still more largely planted in America than any other variety of gooseberry. This is doubtless largely due to the fact that comparatively little has been done toward improving the gooseberry in America during the past fifty years. The most work seems to have been done by William Saunders, late Director of the Dominion Experimental Farms, the originator of the Pearl, Josselyn (Red Jacket), and many other seedlings and crosses not yet on the market. There is a good field for work in improving the native gooseberries, as there is no apparent reason why the size should not be equal to the best English varieties. The quality of the American varieties is considered by some to be better than the average English gooseberry, but the flavor is not nearly so good as the best of the English sorts.



1663. Ribes Grossularia in bloom. (Natural size)



1664. Leaves of Ribes Grossularia. (Natural size)

As the gooseberry is found growing wild almost or quite to the Arctic circle, its culture will no doubt be extended very far north. The most useful native species is the smooth gooseberry, *Ribes hirtellum,* which is found wild from the Atlantic to the Pacific. Next in importance is the prickly gooseberry, *Ribes Cynosbati,* which has not so wide a range. Both of these gooseberries are of good quality. An interesting hybrid gooseberry was originated by Saunders by crossing *Ribes Cynosbati,* with Warrington, a cultivated English variety. The size of the fruit was increased very much, but the gooseberry although good in quality remained prickly. If greater hardiness is desired it may be got in *Ribes lacustre,* which grows almost or quite to the Arctic circle. In its present state it is not nearly so useful as the other two species, the fruit being smaller and inferior in quality. There are other native species, such as *Ribes Lobbii, R. divaricatum,* and *R. rotundifolium,* which may also play their part in the future improvement of the native gooseberry.

There is a steady though limited demand for gooseberries in America, but the gooseberry has never been generally popular on this continent. In England, gooseberries are used in great quantities for eating out of hand and for jam; in America few are used raw, most of the fruit being picked green and put into pies, or used as jam or canned. Those who are successful in growing the English varieties in America are usually enthusiastic in their praise as a fruit for eating raw.

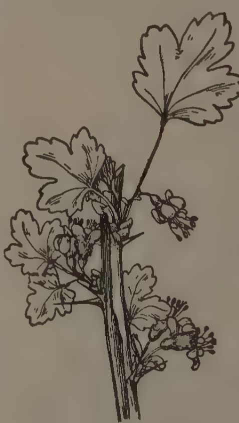
Propagation.

Gooseberries may be propagated either from cuttings or by layering. The average person will usually get the best results from layering, as cuttings are often very unsatisfactory. To propagate by layering, the bushes should be pruned severely in the autumn. This will induce a strong growth of young wood the next season. When these have made most of their growth, which will be early in July, the earth is heaped up around and through the bush until only the tips of the young shoots are left uncovered. The soil is packed down and then a covering of loose earth thrown over to retain moisture better. Most of the American varieties will have rooted well by autumn, and the young plants may be detached and planted in nursery rows either the same fall or the following spring, to be grown there for one season. English varieties usually take two years to root, and the soil must be left about the bushes for that time. Cuttings of American varieties will sometimes give fairly satisfactory results if made from well-ripened wood and treated as currant cuttings. The cuttings are made 6 to 8 inches or less in length, and buried in soil over winter. In spring they are set out in nursery rows, planting deep enough so that only one or two buds are above ground. Both American and English varieties may be propagated from greenwood cuttings in a greenhouse, or hotbed with bottom heat.

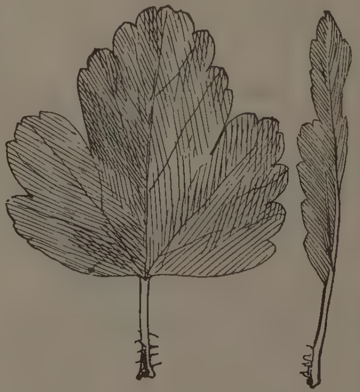
Soil, planting and culture.

The gooseberry is a moisture-loving plant, hence a soil should be chosen in which there will be a constant supply of water during the growing season. In dry soils gooseberries suffer very much in a dry time, the foliage often falling prematurely and the fruit being scalded by the sun. The soil should be a cool one. Moist soils are usually cool, but the surface of a sandy loam soil gets very hot in the summer, hence is not the best for this fruit. Well-drained, heavy clay loams are the most suitable for gooseberries as these usually are both cool and moist. The soil should have abundant plant-food easily made available. A good application of well-rotted manure thoroughly worked into the soil will do much to bring about these favorable conditions. The soil should be well prepared and made mellow as for a crop of roots. As gooseberries start to grow early in the spring it is usually preferable to plant in the autumn, and as the leaves drop early they may be planted in September and will be in good condition when winter comes. Well-rooted cuttings or layers may be used as plants. They should be set in rows about 6 feet apart and 4 feet apart in the rows.

Cultivation should be thorough to retain moisture and keep the soil cool, and as gooseberry roots near



1665. Ribes hirtellum in bloom. (×⅔)



1666. Leaves of Ribes hirtellum (Natural size) the surface, tillage should be shallow. Mulching with straw is sometimes advisable to keep the soil cool.

As the gooseberry makes much more wood than it is desirable to leave, severe pruning is necessary. English varieties are usually trained to a single stem, but this is not necessary, although the freer circulation of air when trained in this way may help to prevent the spread of mildew. The usual custom in America is to grow the gooseberry in bush form. The bush should at first be brought into a good shape by leaving a few of the strongest shoots regularly distributed to make an open head. Five or six of these shoots are quite sufficient to leave at first. As the bush gets older, new shoots are allowed to grow to take the place of the older ones, as the pruning should be done with a view to having only vigorous bearing wood. Fruit is borne on year-old wood and from spurs on older wood. It usually is not desirable to have any wood more than three years old. The best time to prune is in the autumn or winter. The weakest young shoots should be cut off at the ground, also all the stronger young shoots not required for fruiting or to take the place of the older branches to be cut away. The side shoots from the older branches should be headed back or cut out altogether so as to maintain a fairly open head, making it as easy as possible to pick the fruit and yet leaving sufficient wood to produce a good crop and shade the fruit from the sun, as in a hot dry time gooseberries are liable to be injured by scalding. When branches are more than three years of age they should be removed to make way for younger wood. It is advisable to cut out all branches which touch the ground as there will then be a better circulation of air, and the fruit will be kept off the ground. Gooseberries will often begin to bear the second year after planting, but there will not be a full crop until the fourth season. If the soil is kept in good condition by an annual application of well-rotted barnyard manure in the autumn, harrowed in the following spring, and if the bushes are kept sprayed and well pruned, the plantation will not need to be renewed for many years. Sometimes a plant is trained to a single stem (Fig. 1669), to secure extra fine fruit, but it is only a home-garden practice and scarcely to be recommended.

1667. An American gooseberry, Ribes hirtellum. (×½)

Yield of gooseberries.

The American gooseberry is a productive fruit and averages a good crop if well cared for. It is, however, very important to have good foliage to protect the fruit from the sun, and unfortunately many let the currant worm destroy a large proportion of the foliage, and if the weather is hot the fruit suffers. Six bushes of the Pearl have averaged at the Central Experimental Farm, Ottawa, Canada, in five years at the rate of 12,402 pounds an acre each year, or, at forty pounds to the bushel, over 310 bushels an acre. The highest yield was in 1905, when five bushes of Pearl 6 x 4 feet apart yielded seventy-five pounds, or at the rate of 27,225 pounds an acre, equal to over 680 bushels.

The highest yield mentioned by Card in his work on "Bush Fruits," is at the rate of 450 bushels an acre, obtained at the Geneva Experiment Station, New York. He gives the probable range from 300 to 500 bushels an acre. Bailey gives the average as 100 bushels an acre.

European gooseberries.

In Great Britain the gooseberry is one of the most popular fruits, and great quantities of the product are grown there every year. They are used to a large extent for eating out of hand when ripe, but are much in demand for making jam. Owing to their large size and good flavor, and their popularity in Great Britain, they were early imported into America, but it was soon found that owing to the gooseberry mildew the European varieties could not be successfully cultivated in most places in which the gooseberry grows. Where the climate approaches nearest to that of Great Britain, and the northern and moister parts of Europe, and there is considerable moisture in the air, not very high summer temperatures, and considerable cloudy weather, the European gooseberry succeeds best. Even in gardens in which there is a great deal of vegetation giving off much moisture, and in which the soil is shaded and cool, good success is often obtained and almost or quite as fine gooseberries produced as in England, but such instances are the exception.

Heavy clay soils are most suited to the gooseberry and there is little use trying to grow the European varieties in light soils. Clay soils are cool, and with them it is easier to secure the conditions necessary to success. Various methods are recommended for growing European gooseberries free from mildew. Mulching the soil heavily with straw is one. Mulching the soil with coal-ashes is another. Shading the soil with laths set on a frame 8 to 10 feet high is another. All these methods are useful, but unless the air is moist above as it is cool and moist below, the conditions will be still more or less favorable for the development of the disease. The conditions of a thickly planted garden, where there is partial shade, seem the most favorable.

1668. Downing gooseberry.

Varieties of gooseberries.

American: Pearl, Downing (Fig. 1668), Josselyn (Red Jacket). Houghton is the hardiest.

European (of most general adaptation): Whitesmith, Industry (Fig. 1671).

European (least affected by mildew at Central Experimental Farm, Ottawa, Canada): Companion, Eagle, Glenton Green, Queen of Trumps, Snowball.

European (grown by R. B. Whyte, Ottawa, Canada, under garden conditions): Triumph, Lofty, Green Ocean, Conn, Weatherall, Sportsman.

1669. Gooseberry trained in tree form.

Scalding of the fruit.

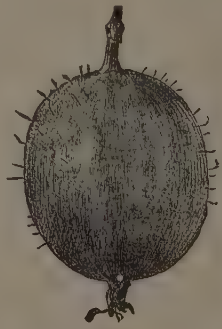
In a very hot dry time, gooseberries are often scalded, become unfit for use and fall to the ground. If the gooseberries are planted in heavy, cool soil and the ground kept well cultivated and the currant-worm prevented from eating the foliage there will be little trouble. Unfortunately, in many plantations the foliage is very scant, either on account of poor cultivation or injury from the currant-worm, and it is under such conditions that the greatest injury occurs.

Insects and diseases affecting the gooseberry.

Currant-worm or imported sawfly (*Pteronus ribesii*, Scop.).—By far the best known of all the insects which injure currants and gooseberries is the currant-worm. The black-spotted dark green false caterpillars of this insect may unfortunately be found in almost every plantation of currants or gooseberries, every year in almost all parts of the temperate regions of North America. The white eggs are laid in rows along the ribs of the leaf on the lower side, toward the end of May. From these the young larvæ hatch and soon make their presence known by the small holes they eat through the leaves. Unless promptly destroyed, they will soon strip the bushes of their leaves, thus weakening them considerably so as to prevent them ripening fruit the first year, and also reducing the quality of the crop of the following season. There are at least two broods in a season. The first appears just as the leaves are attaining full growth, and the second just as the fruit is ripening. The perfect insect is a four-winged fly which may be seen flying about the bushes early in spring. The male is blackish, with yellow legs and of about the same size as a house-fly, but with a more slender body. The female is larger than the male and has the body as well as the legs yellow. *Remedy:* For the first brood a weak mixture of paris green, one ounce to ten gallons of water, may be sprayed over the bushes, or a dry mixture one ounce of paris green to six pounds of flour may be dusted over the foliage after a shower or when the leaves are damp with dew. For the second brood paris green must not be used, but white hellebore; this is dusted on as a dry powder; or a decoction of this powder, one ounce to two gallons of water, may be sprayed over the bushes. It is, of course, far better to treat the first brood thoroughly, so as to reduce the number of females which would lay eggs for the second brood.

1670. Crown Bob, an Engish gooseberry. (×¾)

Gooseberry fruit-worm (*Zophodia grossulariæ*, Pack.).—Just before gooseberries ripen, clusters of two or three may sometimes be noticed, which are prematurely colored, and which are joined together by the webs spun by the caterpillar of a small moth. These caterpillars are pale greenish white and sometimes have a reddish tinge. They live inside the berries and, when the contents of one berry are consumed, attack another near at hand, joining it to the first by a silken web. When full grown they fall to the ground and spin brown parchment-like cocoons, just beneath the surface of the ground. The moths, which are pale gray, marked with dark streaks and bands, are very rarely observed. They fly early in spring, and there is only one brood in the year. *Remedy*: The best method of controlling this insect, which fortunately is never very abundant, is to pick by hand the clusters of injured berries. It is thought that chickens and other poultry are useful in destroying the larvæ and chrysalids; and it is certain that, while chickens are very small, they are useful in a garden in destroying a great number of injurious insects. The old hen, however, should be kept securely cooped up and not allowed to run at large.



1671. Industry, one of the English gooseberries. (Natural size.)

Gooseberry mildew (*Sphærotheca mors-uvæ*).—The gooseberry mildew has prevented the general culture of the European gooseberry in America. This disease attacks the leaves, twigs and fruit. When the attack is bad it destroys the foliage, covers the fruit and causes most of it to drop. It saps the growing shoots to such an extent that they do not ripen properly, and dry up without setting fruit-buds. It thus practically destroys the crop. The disease is apparent early in the season in the web-like covering which coats the leaves, shoots and fruit. This is the mycelium from which is given off the spores which propagate this disease. It is usually noticed first in the lower and most shaded parts of the bush. When the spores are being given off, the mildew has a powdery appearance. Winter-spores are formed later which germinate in the spring. As the mycelium and spores are both on the surface it might be thought this disease could be easily controlled, but the weather conditions in this country seem so favorable to the development of spores that the gooseberry mildew spreads with great rapidity, and constant and thorough spraying is necessary to prevent it from doing so. American varieties are seldom affected by gooseberry mildew, although occasionally they are slightly attacked. *Remedies:* So far, there has been no good remedy for the gooseberry mildew, but the most promising remedy is the lime-sulfur wash applied first when the buds are breaking and then at intervals during the growing season. So far, the best formulas and the best times to spray have not been accurately worked out. Potassium sulfide in the proportion of one ounce to two gallons of water has controlled the mildew in some cases but to secure satisfactory results the weather must be favorable and the bushes sprayed from four to six times or more. In some cases it has been found that it is not practicable to control the mildew with this spray; furthermore under certain conditions the foliage of some varieties is injured by the spray. Bordeaux mixture when the leaf-buds are breaking and again just before blooming is a partial preventive.

Leaf-spot, rust (*Septoria ribis*).—The disease which causes the spotting of gooseberry leaves and their falling prematurely is the same as that which affects currants, and may be dealt with in the same way.

W. T. Macoun.

GOOSEBERRY, BARBADOES: *Pereskia.*

GOOSEFOOT: *Chenopodium.*

GORDÒNIA (after James Gordon, an English nurseryman; died 1780). *Theàceæ.* Including *Franklínia.* Ornamental woody plants grown for their showy white flowers and handsome foliage.

Evergreen or deciduous trees or shrubs: lvs. alternate, petioled, entire or serrate: fls. solitary, axillary; sepals and petals 5; stamens numerous; ovary superior, 3–6-celled, each cell with 4 or numerous ovules; style slender, with a 3–6-lobed stigma: caps. 3–6-celled, woody, dehiscent, with few or many winged seeds in each cell.—About 15 species in Subtrop. and Trop. Asia and 2 in the S. Atlantic States.

The gordonias have very handsome shining foliage, and produce their large white flowers even on rather small plants. Only *G. alatamaha* is hardy north to Massachusetts, while the others are cultivated only in subtropical regions. They grow best in a somewhat moist, peaty, or sandy soil. Propagated by seeds, layers or cuttings from half-ripened wood under glass.

A. *Foliage deciduous.*

alatamáha, Sarg. (*G. pubéscens,* L'Her. *Franklínia alatamáha.* Marsh.). Shrub or tree, to 30 ft.: lvs. obovate-oblong, narrowed into a short petiole, sparingly serrate, bright green and shining above, pubescent below, turning scarlet in fall, 5–6 in. long: fls. short-pedicelled, pure white, about 3 in. across; petals roundish obovate, with crenulate margin, concave: caps. globular. Sept., Oct. Ga., but not found again since 1790. S.S. 1:22. Mn. 6:201. Gng. 7:167. M.D.G. 1899:25. F.E. 30:863. C.L.A. 2:34.—One of the few trees that flower in autumn. It does well in Mass. in sheltered positions or with slight protection, and blooms freely every year. A large tree in the Bartram garden, near Philadelphia, was long supposed to be the only living specimen of *G. alatamaha.* All other specimens in cult. are believed to have been prop. from the Bartram tree, which has lately died. All efforts since 1790 to rediscover this tree in the S. have failed.

AA. *Foliage evergreen.*

Lasiánthus, Ellis. Loblolly Bay. Tree, to 60 ft., usually shrubby in cult.: lvs. obovate-lanceolate, narrowed into a short petiole, crenately dentate, dark green and shining above, glabrous, 4–6 in. long: fls. long-pedicelled, white, 2–2½ in. across; petals oblong-obovate; stamens short: caps. ovate. July, Aug. Va. to Fla. and Miss. S.S. 1:21. B.M. 668. I.T. 2:41.

axillàris, Szyszylowicz (*G. anómala,* Spreng.). Large shrub: lvs. oblanceolate, narrowed into a very short petiole, entire or serrate, dark green above, 3–6 in. long: fls. almost sessile, creamy white, 2–3 in. across; petals roundish obovate. Nov. S. China. B.M. 2047; 4019 (as *Polyspora axillaris*). L.B.C. 7:675 and B.R. 349 (as *Camellia axillaris*).

G. grándis, André. Corymbs few-fld., terminal; fls. white, large. R.H. 1906:520.—A handsome greenhouse species.—*G. javánica,* Rollison. See Schima Noronhæ.

Alfred Rehder.

GORSE: *Ulex europæus.*

GOSSÝPIUM (ancient name of the cotton plant). *Malvàceæ.* Cotton. Perhaps thirty or more species of herbs and shrubs of warm countries, although more than 100 have been described; some authorities reduce them to about three. They are grown for the fiber that is borne on the seeds. See *Cotton.* They are scarcely horticultural subjects, and therefore are not treated fully in this work.

Gossypiums are tall stout herbs, or tree-form bushes: lvs. large, alternate, petiolate, mostly prominently 3–9-lobed but sometimes entire: fls. white, yellow or purplish, provided with 3–5 large cordate calyx-like bracts; calyx entire or somewhat 5-lobed; stamens united into a column; ovary 3–5-celled, each cell 3–11-ovuled; style 3–5-lobed: fr. a loculicidally dehiscent caps., bearing seeds that are obovate, rounded or slightly angular, sometimes smooth, but usually covered with a short down or fuzz and a longer coat of brown, creamy or white hairs, called the lint.

The cottons of commerce belong, according to Lewton, to about eight distinct botanical types and may be divided into two main groups, the New World and the Old World cottons. The New World group includes American Upland cotton (*G. hirsutum,* Linn.); Sea Island and Egyptian cottons (*G. barbadense,* Linn.); and the tropical tree cottons of South America (*G. brasiliense,* Macf. and *G. peruvianum,* Cav.). The Old World cottons include the Levant cotton (*G. herbaceum,* Linn.), cultivated in southern Europe and western Asia; the oriental tree cotton (*G. arboreum,* Linn.), with yellow or purple-red flowers; the common cotton of India (*G. neglectum,* Todaro); and the Chinese and Japanese cottons (*G. nanking,* Meyen.).

Cotton (probably *G. herbaceum*) was grown in gardens in Delaware and Maryland in colonial times as an ornamental plant.

Two species have been offered as ornamental plants. **G. Dàvidsonii,** Kellogg, from Lower Calif. and Cerros Isls., woody, with handsome yellow fls. purple at the base, 1 in. long, and small cordate mostly entire lvs. **G. Stùrtii,** F. Muell., endemic in interior of Australia; shrub, several feet high, more or less marked with black dots: lvs. broadly ovate, entire, 1–2 in. long, glaucous: fls. large, purple with dark center; bracts to 1 in. long, cordate, entire, many-nerved, black-dotted. The common fiber-cottons are sometimes planted in northern gardens for curiosity, but they seldom make attractive plants where the nights are cool; sometimes they are seen in warm glasshouses, with other economic plants.

L. H. B.

GOUÀNIA (Antoine Gouan, 1733–1821, professor of botany at Montpelier, France). *Rhamnàceæ.* About 40 species of tropical shrubs, sometimes tall climbers, tendril-bearing: branches long and slender: lvs. alternate, petiolate, penninerved, entire or dentate: fls. in clusters, on axillary and terminal, elongated peduncles; disk 5-lobed; style 3-fid: caps. with 3 indehiscent berries.—This genus includes the "chawstick" of Jamaica, a rapid-growing, shrubby vine, with pretty heart-shaped lvs., grown sometimes for ornament in the extreme S. It is suitable for screening unsightly objects. The sts. are chewed in the W. Indies. Tooth brushes are made from the frayed ends and tooth-powder from the pulverized wood.

domingénsis, Linn. Chawstick. Lvs. usually 1½–2 in. long, elliptical, glabrate, with distant serratures; veins tapering toward the margin: fls. very small, in slender interrupted axillary more or less leafy spikes: caps. winged, emarginate. W. Indies.

L. H. B.

GOURD. In England, a generic name for species of Cucurbita (which see). In America the term is used to designate those cucurbitous fruits that are hard-shelled, and are used for ornament or for the making of domestic utensils. The gourd of history is probably Lagenaria. In the northern United States, the small hard-shelled forms of *Cucurbita Pepo* (var. *ovifera*) are commonly understood when the word gourd is used. The gourds in the American trade are referable to their species as follows:

Anaconda, *Lagenaria vulgaris.*
Apple-shaped, *Cucurbita Pepo* var. *ovifera.*
Bicolor, *Cucurbita Pepo* var. *ovifera.*
Bonnet, *Luffa.*
Bottle-shaped, *Lagenaria vulgaris.*
Calabash. *Crescentia Cujete,* yields the true calabash; but the calabash gourd is *Lagenaria vulgaris.*
Coloquinte, *Cucurbita Pepo,* var. *ovifera* (Colocynth is *Citrullus Colocynthis*).
Dipper, *Lagenaria vulgaris.*
Dipsaceous, *Cucumis dipsaceus.*
Dish-cloth, *Luffa.*
Egg, Egg-shape, *Cucurbita Pepo* var. *ovifera.*
Gooseberry, *Cucumis Anguria.*
Hedgehog, *Cucumis dipsaceus.*
Hercules' Club, *Lagenaria vulgaris.*
Maté Gourd, small form of *Lagenaria vulgaris.*
Mock Orange, *Cucurbita Pepo.*
Onion-shaped, *Cucurbita Pepo.*
Orange, *Cucurbita Pepo* var. *ovifera.*
Ostrich Egg, *Cucumis dipsaceus.*
Pear-shaped, *Cucurbita Pepo* var. *ovifera.* (Fig. 1134).
Powder Horn, *Lagenaria vulgaris.*
Rag, *Luffa.*
Serpent or Snake (not Snake cucumber, which is a Cucumis), *Lagenaria vulgaris* and *Trichosanthes.*
Sponge, *Luffa.*
Spoon, *Lagenaria vulgaris.*
Sugar Trough, *Lagenaria vulgaris.*
Tashkent, *Cucurbita Pepo* var. *ovifera.*
Turk's Turban, *Cucurbita Pepo* var. *ovifera.*
Vegetable Sponge, *Luffa.*
Wax Gourd, *Benincasa hispida.*

L. H. B.

GOURLIÈA (Gourlié, a personal name). *Leguminòsæ.* One or two spiny shrubs or small trees of Chile, one of which is listed in S. Calif., somewhat akin to Sophora and Cladrastis: lvs. odd-pinnate, the lfts. small: fls. small, orange-colored, in racemes or fascicles, papilionaceous; standard orbicular, wings obovate and undulate, keel short: pod short, indehiscent. **G. spinòsa,** Skeels (*Lucùma spinòsa,* Molina. *G. chilénsis,* Gay). CHAÑAL. Tree, 12–15 ft., with long thick branches ending in spines: lfts. 3 pairs, ovate: fls. orange-yellow streaked red, in short loose racemes: fr. about 1 in. diam., brownish, the pulp the flavor of jujube: wood yellow and hard, used for cabinet-making. Chile, at elevation of 1,500–5,000 ft. L. H. B.

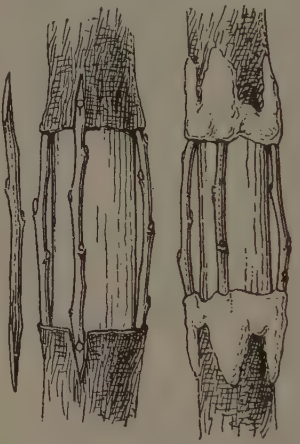
GOVÈNIA (J. R. Gowen, English gardener). *Orchidàceæ.* Terrestrial orchids of Trop. Amer., seldom cult., of perhaps a dozen species: rhizomes thickened into tuber-like enlargements or pseudobulbs, the sts. erect and few-lvd.: lvs. large, narrowed at base: fls. in simple racemes, medium in size, short-pedicelled, mostly white, cream-colored or yellow and more or less red-spotted; sepals and petals of about equal length, the former connivent; lip very short, without spur, jointed to column; pollinia 4, broadly ovate. *G. tingens,* Poepp. & Endl. Height 2–3 ft.: lf.-blade elliptic, about 8 in. long: fls. yellowish, with transverse purple lines, much larger than those of *G. superba;* segms. lanceolate to oblong. Peru. *G. supérba,* Lindl. Two ft.: fls. fragrant, yellow with red markings, sepals and petals acute: spike loose, erect. Mex. L.B.C. 18:1709. *G. sulphùrea,* Reichb. f. An odd species with onion-like pseudobulbs: lf.-blade cuneate-lanceolate and acuminate: fls. rather large; sepals sulfur-yellow; petals white with yellowish margin and purple lines; lip cordate-oblong, white with dark brown at apex.

L. H. B.

GRABÒWSKIA (H. E. Grabowsky, German apothecary and botanical author). *Solanàceæ.* A half-dozen or more spiny shrubs of Trop. and extra-Trop. S. Amer., with small violet or pale blue or whitish fls. borne singly at the nodes and in clusters on the ends of the branches, and oblong or obovate entire sometimes fleshy lvs.: calyx 5-toothed or becoming 10-toothed after flowering; corolla funnelform, with short tube and 5-lobed spreading limb; stamens 5, exserted: fr. drupe-like with 2 pyrenes. **G. boerhaaviæfòlia,** Schlecht. (*G. glaùca,* Hort.), of Peru, is offered in Calif. It is a lycium-like scrambling or wide-spreading bush with small lvs. alternate and tufted, with spines ¼in. long in the axils and the shorter branches often also sharp and spine-like: fls. whitish or pale blue, not conspicuous, in clusters of 3–5 or solitary: berries scarcely ½in. long. B.R. 1985.—In Calif., the plant has a good gray-green foliage and a graceful drooping habit, therefore making it adaptable for planting compositions in landscapes. L. H. B.

GRAFTING, Multiplication by. Grafting is the operation of inserting a part of one plant into another plant or part with the intention that it shall grow and produce its kind.

The practice of grafting, together with all the reasons, consequences and results, constitutes a department of knowledge known as *graftage.* The term *grafting* is ordinarily restricted, in popular speech, to propagation by means of short twigs or cions, and *budding* is used to designate the insertion of single buds that are severed from the branch on which they grew; but these distinctions are not fundamental. *Stock* is the plant or part on which the grafting is done. *Cion* (*scion, sion*) is the part inserted into the stock, although it is usually restricted to cuttings of twigs, and does not include detached buds. In many writings the word is spelled *scion,* but the other is shorter and it was a very early horticultural term, many old horticultural writings using *cion* and *cyon. Scion* is apparently later, and usage is not uniform. The word *graft* is sometimes used in the sense of *cion,* but it would better be used for the completed thing—the new plant or part made by the joining of cion and stock.



1672. Bridge-grafting. At the left, a cion; the cions in place; at the right, the ends waxed.

Grafting is not always employed for purposes of propagation. It may be a reparative process. What is known as bridge-grafting is of this kind. Wounds or girdles may be bridged by cions, as in Fig. 1672 (after Hedrick), for the purpose of supplying new tissue to connect the parts. Here the edges of the girdle are trimmed to the fresh firm tissue, cions whittled wedge-shape at each end are inserted, bandages are drawn around the trunk to hold the free edges of the bark and the ends of the cions, and wax is poured over the work. This operation is performed in spring, with dormant cions. The buds should not be allowed to throw out shoots. If the cions are placed close together, they will soon unite along their sides and make a continuous covering of the wound. Writing of bridge-grafting, Hedrick says (N. Y. Sta. Circ. No. 17): "Its most important use is to preserve trees injured or girdled by rodents or disease. Any ragged or diseased edges should be cleanly cut away, a longitudinal slit should be made in the bark, both above and below the wound, and the edges of the slits loosened slightly. A cion should then be cut 2 or 3 inches longer than the space to be bridged, one side beveled off at both ends (Fig. 1672), and inserted in the slits, its beveled face against the wood of the trunk. In order to guard against any accidental displacement it would be well to drive a small tack or nail through each end of the cion, which, however, must not be split in the operation. Other cions in a like manner may be inserted at intervals of about 2 inches over the entire injured surface. The ends of the cions should be covered with wax but it is not necessary to cover all the bridged portion of the trunk. If the tree operated upon is small and likely to weave in the wind it should be tied firmly to a strong stake as such movements might tear apart the tender uniting surfaces."

Cions are sometimes inserted freely in the stub left by a large broken limb, for the double purpose of providing other shoots to take the place of the branch and of facilitating the healing of the wound. Sometimes cions are inserted in limbs on a one-sided or misshapen tree for the purpose of securing better growth on that side, the variety perhaps being the same as that of the tree itself.

Another reason for grafting is to produce some radical change in the nature of the cion, as rendering it more dwarf, more fruitful, or otherwise changing its habit. Still another office is to adapt plants to adverse soils or climates. An example is the use of the peach root in the southern states upon which to work the plum, as the peach thrives better than the plum in sandy soils. The practice in Russia of working the apple on roots of the Siberian crab is an example of an effort to make a plant better able to withstand a very severe climate.

In general, however, grafting is employed for the purpose of multiplying or perpetuating a given variety, mostly of woody plants. It is used with plants that do not bear seeds, or in which the seeds do not come true or are difficult to germinate, or when the plants do not propagate well by cuttings or layers. It is also employed to increase the ease and speed of multiplying plants.

In common practice, the effect of the stock on the cion is rather more mechanical or physical than physiological or chemical. The influences are very largely those associated with greater or less growth. As a rule, each part of the combined plant—the stock and cion—maintains its individuality. There are certain cases, however, in which the cion seems to partake of the nature of the stock; and others in which the stock partakes of the nature of the cion. There are recorded instances of a distinct change in the flavor of fruit when the cion is put upon stock that bears fruit of very different character. There are some varieties of apples and pears which, when worked on a seedling root, tend to change the habit of growth of that root. Examples are Northern Spy and Whitney apples, which, when grafted on a root of unknown parentage, tend to make that root grow very deep in the soil. All these instances seem to be special cases, or exceptions to the general rule that each part maintains its individuality. Reasons for this change of nature in these cases have not been determined, and in most cases such results are not to be predicted. The most marked effect of stock on the cion is a dwarfing influence. Dwarfing may be expected whenever the stock is of a smaller stature than the cion. The most familiar example is the dwarf pear, made by working the pear on quince stock. Supplying a plant with a slow-growing root is only the beginning of the making of a dwarf. The plant must be kept dwarf by subsequent pruning and other care. There is comparatively little demand for large-growing forms of woody plants, whereas there is much demand for dwarf forms. See *Dwarfing*, page 1082.

The limits within which grafting can succeed are to be determined only by experiment. These limits are often within the species, and usually within the genus, but there are instances in which plants of distinct genera intergraft with success, as in some of the cacti. In general, the closer the affinity of cion and stock, the better the union. When stock of the same species can not be secured, it is allowable to chose another species. Thus it was for a time impossible to secure Japanese plum stocks upon which to grow the varieties of Japanese plums, and peach, Marianna, myrobalan and domestica plum stocks have been used, and are used to this day. In some cases another species grows more readily from seed, is cheaper, is less liable to fungous injury in the nursery, or has some other practical advantage. Thus, most domestica plums (*Prunus domestica*) in the North are worked on the myrobalan (*P. cerasifera*); many sweet and sour cherries (*Prunus Avium* and *P. Cerasus*) are worked on the mahaleb (*P. Mahaleb*); many kinds of roses are worked on manetti and *Rosa multiflora* stocks.

From time to time there arises an agitation against grafting, particularly in the Old World. Cases of poor unions and the difficulties of sprouting from the root or stock are cited as proofs that graftage is injurious and devitalizing. But these are examples of poor results. They show what should not be done. Properly performed, on plants of proper affinity, graftage is not devitalizing. It is essential to modern horticulture.

The ways or fashions of grafting are legion. There are as many ways as there are ways of whittling. The operator may fashion the union of the stock and the cion to suit himself, if only he apply cambium to cambium, make a close joint, and properly protect the work. Thus, Thouin in his "Monographie des Greffes," 1821, describes 119 kinds of grafting. All kinds of grafting may be classified into three groups:

1. Bud-grafting or budding. In the old days called inoculation.
2. Cion-grafting, or what is now thought of as grafting proper.
3. Grafting by approach, sometimes called inarching.

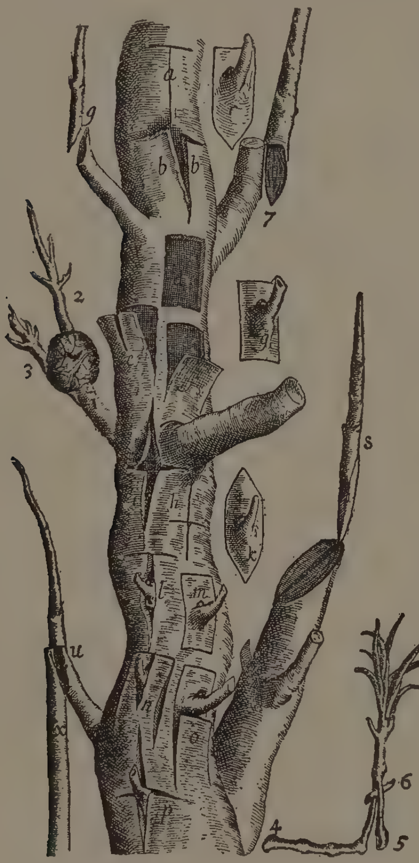
Early practice.

Grafting is one of the oldest of the arts of plant-craft. It is probable that the real art of grafting was held more or less as a professional or class secret in the ancient world, for the writers seem to have only the vaguest notion of its possibilities and limitations. Virgil writes (Preston's translation):

> But thou shalt lend
> Grafts of rude arbute unto the walnut tree,
> Shalt bid the unfruitful plane sound apples bear,
> Chestnuts the beech, the ash blow white with the pear,
> And, under the elm, the sow on acorns fare.

It seems to have been a popular misconception that any kind of plant will grow on any other. Pliny asserts that the art of grafting was taught to man by nature. Birds swallow seeds, and these seeds, falling in "some cleft in the bark of a tree," germinate and make plants. "Hence it is that we see the cherry growing upon the willow, the plane upon the laurel, the laurel upon the cherry, and fruits of various tints and hues all springing from the same tree at once." This, of course, is not grafting at all, but the implanting of seeds in earth-filled chinks and cracks, in which the plants find a congenial foothold and soil. But the ancients have left us abundant testimony that genuine grafting was employed with success. Pliny describes a cleft-graft. He gives several precautions: the stock must be "that of a tree suitable for the purpose," and the graft must be "taken from one that is proper for grafting; the incision or cleft must not be made in a knot; the graft must be from a tree "that is a good bearer, and from a young shoot;" the graft must not be sharpened or pointed "while the wind is blowing;" "a graft should not be used that is too full of sap, no, by Hercules! no more than one that is dry and parched;" "it is a point most religiously observed, to insert the graft during the moon's increase."

Herein are seen the beginnings of the grafting practices of the present day, together with some practices of layering. Sharrock treated the whole subject of grafting under the head of "Insitions," and here he minutely describes the cleft-graft, and speaks of it as "the common way of grafting." The practice which we now know as inarching or grafting by approach, he significantly calls "Ablactation" (that is, *suckling* or *weaning*). Now that so much is said about the proper and careful selection of cions, it is interesting to read Sharrock's advice on this subject: "Good bearing trees are made from Cyons of the like fruitfulness. . . . Cyons are best chosen from the fairest, strongest shuits, not from under shoots or suckers, which will be long ere they bear fruit, which is contrary to the intention of grafting." But we have seen that Pliny gave similar advice before the Christian era,—which is only another illustration of the fact that most of our current notions have their roots deep in the past.



1673. Sharrock's illustration of grafting. 1672.

The accompanying cut (Fig. 1673) reproduced two-thirds size from Robert Sharrock's "History of the Propagation and Improvement of Vegetables," 1672, shows various kinds of grafting in vogue over two centuries ago. Following is the literal explanation of the plate:

a. Denotes the ordinary cutting of the bark for inoculation.
bb. The sides of the bark, lifted up for the putting in of the shield.
c. The shield taken off with the bud, which lies under the stalk of the leaf cut off.
ln. The shield put into the stock to be bound up.
d. The bark cut out in an oblong square, according to another usual way of inoculation.
g. The shield cut out for the fitting the disbarked square.
m. The same shield put into the stock.
f. A variation of the forementioned way, by cutting off the upper part of the oblique square, and binding the lower part down upon the shield.
o. The shield so put in to be bound up.
e. Another variation by slitting the bark, that the bud and leaf may stand forth at *e*, and the bark slit be bound down upon the shield.
h. A cross cut for inoculation.
i. The same cross cut lifted up in this figure, somewhat too big.
k. The shield cut off to be put therein.
p. The shield put in.
g or *q.* The cut of cyon or stock for whip-grafting.
r 7. The cut of cyon and stock for shoulder-grafting.
s. The cut of the cyons, and slit of the stock for grafting in the cleft.
x. The stock set for ablactation or approach.
u. The cyon of the branch for the same operation.
1 2. The branch that is to be taken off by circumposition.
3. The branch that bears up the mould to the disbarked place.
4. The branch of a carnation to be laid.

6. The next joynt where the slit is propped open, with a piece of a carnation leaf put in.

Budding.

The operation of budding consists of inserting a single detached bud underneath the bark of the stock. It is employed only in stocks of small diameter, and preferably in those not more than one year old. The operation may be performed whenever the bark will peel and whenever mature buds may be secured. The bark will peel in early spring and again in late summer or early autumn, and the operation of budding in the open ground is therefore performed at those times. In the spring the buds are secured from twigs of the previous season's growth. At the second budding season, in late summer or early autumn, the buds are secured from growing twigs of the season. At that time of the year the buds will be sufficiently developed to be easily recognized and handled.

Budding is much employed in nurseries. Peaches, cherries, plums, and most stone fruits, are habitually budded rather than cion-grafted. In the East, apples and pears are usually budded in the nursery; but in the West apples at least are usually root-grafted. Third-rate stocks are sometimes set in nursery rows and budded the following July.

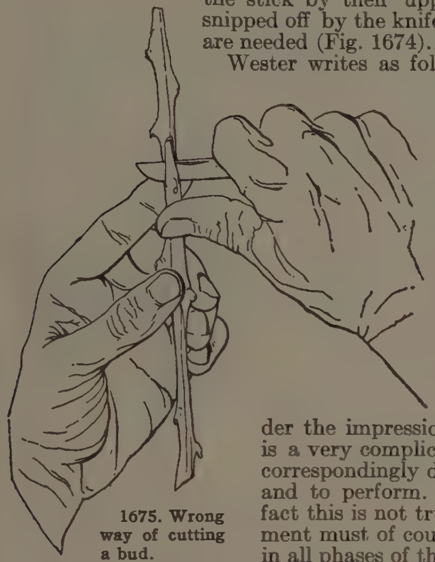
It is practicable to insert buds rather than cions in the tops of young trees, for the purpose of changing the tree into a different variety. Sometimes the buds are inserted in limbs two and three years old; but it is usually preferable, if the tree is of some age, to cut back the tree somewhat heavily the previous season or the previous spring, to get a growth of suckers into which the buds may be set.

The cutting from which the buds are taken is known to budders as *a stick* (Fig. 1674). In early spring-budding, this stick is the last year's growth of the variety which it is desired to propagate. Later in the season, the stick is the twig grown in that season. Not all the buds on the stick are strong enough or good enough for budding. The budder will usually discard the weak ones at the top and at the bottom, unless he is very much pressed for buds, as may be the case with new or rare varieties. If the stick is taken late in the season the leaves will be on; but these are quickly cut off to prevent too much evaporation from the cutting. About ¼ inch of the leaf-stalk is left to serve as a handle to the bud.

1674. Stick of buds. (×⅓)

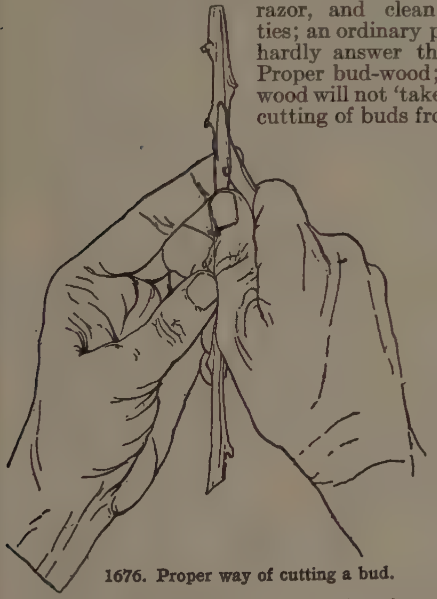
Shield-budding.

The ordinary operation of budding is shown in the illustrations. It is known as shield-budding, from the shape of the removed bud. With a thin-bladed, sharp knife, the operator slices off the bud by placing his thumb beneath the bud and making a deft and quick stroke of the blade. Just under the bud he cuts a little into the wood. Some budders afterward remove this bit of wood; but this is not essential. If this wood is somewhat hard and dry, or if it carries some pith, it may then serve to dry out the bud or to prevent intimate contact with the cambium of the stock. In ordinary operations this truncheon of wood is not removed. Most budders cut all the buds on a stick before they insert any of them; but they are allowed to hang to the stick by their upper ends, being snipped off by the knife as fast as they are needed (Fig. 1674).



1675. Wrong way of cutting a bud.

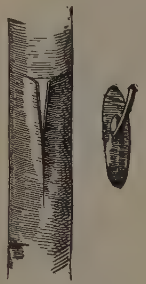
Wester writes as follows on the requirements in budding citrus fruits (Bull. No. 27, Bur. Agric., Philippine Isls.), and the directions will apply to other plants; and he gives pictures (Figs. 1675, 1676) of part of the manual operation: "Many people are under the impression that budding is a very complicated operation, correspondingly difficult to learn and to perform. As a matter of fact this is not true. Some judgment must of course be exercised in all phases of the work, but the art of budding itself is a mere matter of manual skill that anyone should be able to master who is at all deft in the handling of a knife. Necessary essentials for success are: (1) Stock plants in condition for budding; i. e., the flow of sap must be good so that the bark separates readily from the wood. (2) A suitable budding-knife, the edge of which should be sharp and keen as a razor, and clean of all impurities; an ordinary pocket-knife will hardly answer the purpose. (3) Proper bud-wood; immature bud-wood will not 'take' and the proper cutting of buds from old and hard bud-wood is difficult. (4) The bud-wood should never be allowed to dry out by being exposed to the air or sun. (5) The buds should be inserted immediately after being cut, and the bud tied at once. (6) No foreign matter or water should be allowed to enter the bud incision. (7) The bud should be cut so that there is no break or tear in its tissues."



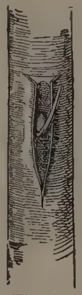
1676. Proper way of cutting a bud.

The stock is first prepared by removing all the leaves and twigs from the area to be budded. In the case of nursery stock, it is customary for a boy to strip the lower leaves of the stock a day or so in advance of the budding. If the stripping is done three or four days or a week before the budding, it will sometimes cause the bark to set and, therefore, interfere with the operation. Nursery trees are usually budded as near the ground as the operator can work—not more than 2 or 3 inches above the surface. In most cases, the budder prefers to set the bud on the north side of the stock, that it may be shaded from the hot sun.

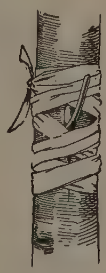
A T-shaped incision, just through the bark, is made on the stock (Fig. 1677). The crosswise incision is usually made first. As the operator takes his knife from the last incision, he gives it a deft turn to right and left and loosens the flaps of the bark, so that the bud is easily inserted. The bud is now taken from the stick and shoved into the matrix underneath the bark until it is entirely within the cleft (Fig. 1678). A boy follows and ties the bud, making four or five deft turns and holding the strand by covering the lower end underneath one of the turns (Fig. 1679). No wax or other mastic is used. Any soft strand may be employed for the tying. It was the old custom to use basswood bark, which was taken in the spring from the inner layers of the bark of the basswood tree. This material was then macerated in water and afterward pounded to make it soft. Yarn is also used. At present, raffia is universally employed. This is the stripping of an oriental palm, and it can be bought in the market and is cheaper than home-made materials; it is also better. It is customary to lay it on the ground or in a damp place over night to soften it and to allow the operator to flatten out the strands. This raffia is cut in the length to suit before the tying is begun, and the bunch of strands is then held underneath the belt or carried in a box. For budding, the operator prefers a small, thin-bladed knife, with a rounded or thumb-shaped cutting surface (Fig. 1680). Budding knives are regularly on the market.



1677. Shield-budding. (×½)

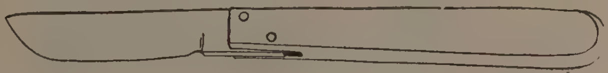


1678. The bud set in the matrix. (×½)



1679. The bud tied.

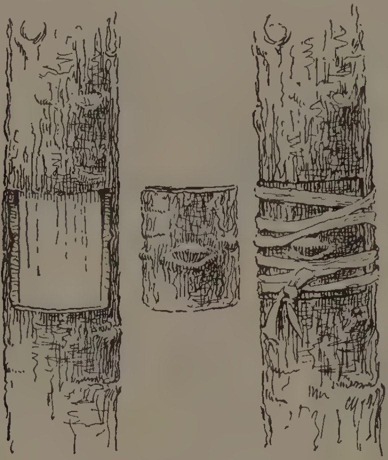
When budding is performed late in the season, the bud does not throw out a shoot until the following spring. It merely grows fast or "sticks" to the stock. Two or three weeks after the setting of the bud, the bandage is cut so that it will not restrict the swelling of the stock. If the stock grows very rapidly, it may be necessary to cut the bandage before that time. Nothing more is done with the tree until the following spring, at which time the whole tree is cut off about 1 inch above the bud. This one bud now throws out a shoot and makes a very heavy growth, being impelled by the strong root. In this first season of growth, a peach tree will attain the height of 4 to 6 feet, and be ready for market in autumn. If the bud is set early in the spring it will throw out a shoot the same season; but ordinarily it would not make the growth in one season that the bud does in the other case. Spring-budding in the open air is rarely employed in nursery practice. It is sometimes used in the top-budding of established



1680. Budding knife. (×½)

plants. In all budding practices, it is important to keep down the suckers from the stock.

In the South, a peach tree may be large enough in June, if the seeds are planted in February or March, to be budded. The bud will grow the same year, and by autumn will make a salable tree. This operation of budding in early summer on stocks which grow that year is known as June-budding. As a rule, June-budded trees are smaller than fall-budded trees; but they can be secured one year sooner.

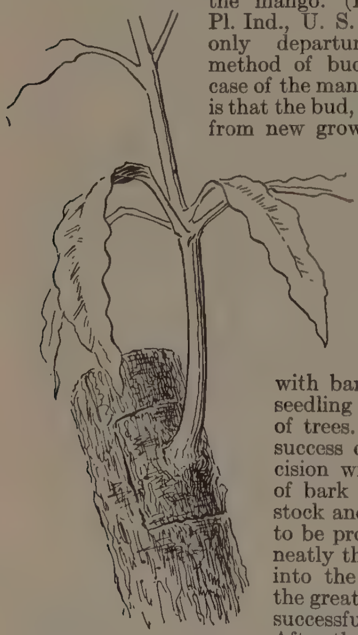


1681. Rectangular patch-budding.

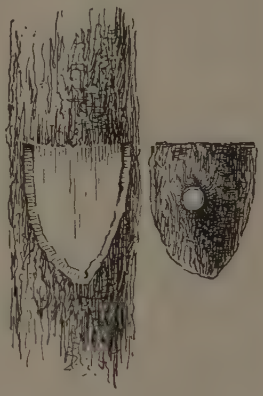
Other forms of budding.

There are many ways of shaping the bud. These modes may have distinct advantage in certain plants, because of the way in which the bark holds its shape, of the relation to the drying out of the parts, and otherwise.

The rectangular-patch method is illustrated by Sharrock (*d*, *g*, *m*, Fig. 1673). It is recently described by Oliver as one of the successful methods of propagating the mango. (Bulletin No. 46, Bur. Pl. Ind., U. S. Dept. Agric.): "The only departure from Sharrock's method of budding as used in the case of the mango at the present time is that the bud, instead of being taken from new growth, must be selected from wood old enough to have lost its foliage. This means that the bud-wood will sometimes be over two years old. The use of bark of this age and even older insures success in budding the mango, as it unites rapidly with bark of a similar age on seedling stocks or on branches of trees. To a certain extent success depends upon the precision with which the section of bark is removed from the stock and also from the variety to be propagated, as the more neatly the bud section is fitted into the space prepared for it the greater the probability of a successful union (Fig. 1681). After the section of bark from the bud-stick is nicely fitted in place, and before tying, a small quantity of grafting-wax should be smeared over the parts where they come together and tied firmly in place with thick strands of raffia. This effectually prevents the admission of air to the spaces which, no matter how carefully the operation be performed, exist between stock and cion; it also serves to prevent moisture from gaining access to the cut surfaces. The cut surfaces and all but the bud should then be covered with strips of cloth dipped in melted paraffin, wrapping being begun at the lower part, so that when finished water will not gain entrance to the wrapped section of bark. If that part of the stock where the bud is tied be exposed to the sun, it is always advisable to furnish shade which is best supplied by strips of paper tied above the bud and extending down over it. Two weeks may be allowed to pass before an examination is made. The cloth wrappings may then be removed and the raffia should be loosened if there is danger of its cutting into the bark. When a sufficient time has elapsed to make certain that a union has taken place, part of the top of the stock should be removed in order to encourage the bud to start. This it will do with very little coaxing. When sufficient growth has been made, all of the stock above the bud may be removed and the cut part coated with liquid grafting-wax or tar to exclude moisture and prevent rotting." Fig. 1682 shows the successful growth of the patch-bud.



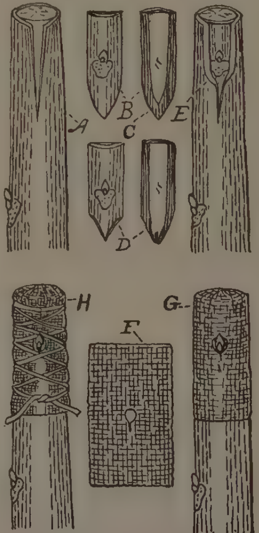
1682. The rectangular patch-bud growing.



1683. Spade-budding.

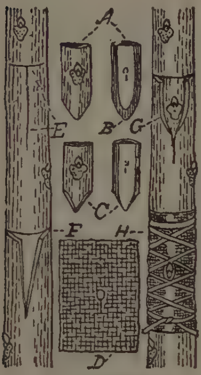
The spade-shaped bud, shown in Fig. 1683, has been employed with the mango and other plants. The pointed end makes it possible, according to Oliver, "to push the bark of the cion down tight against the bark of the stock; the top part is then cut off square with the transverse cut in the bark of the stock, and is pressed firmly into position previous to tying and waxing in the usual way." These two forms of budding are given here only for the purpose of illustrating interesting methods, and not necessarily to advise their use.

Improved methods of budding the pecan have been developed in Texas by Charles L. Edwards. He prefers spring-set buds, as they have the whole growing season before them and make salable trees by autumn. The summer-bud makes only a start before autumn, at best; most of them remain dormant till spring, and not a few dry out and perish. One method is shown in Figs. 1684, 1685. The stocks are cut off bodily, and straight across. A slit is then made in the bark at the top (A), and the bark opened to receive the bud. The buds are cut like shield-buds for peaches and plums (B, front and back views), but in addition, the bark is cut away from the lower end of the bud (C), reducing it to a point so it will slip into place easily (D). By removing the thick rim of bark from the lower end of



1684. Crown-budding the pecan; 1685 (below), the bud wrapped and tied.

the bud, the sap from the stock will enter it easily, and force it into immediate growth, whether put on in early spring or as late as September. At E the bud is shown in place, and the flaps pared. To put on the wrapper, use an oblong little square of waxed cloth with an eyelet in the middle for the bud to emerge from (F). In preparing the cloth for these wrappers, use only beeswax, not grafting-wax for this purpose. Be sure to tie on the wrappers firmly, and see also that they cover the entire top of the stock, leaving no part of the wounds made by the knife uncovered. A modified shield-bud is used by Edwards. In Fig. 1686, the part marked A shows the outside and inside of the bud as commonly made for the pecan; B shows the thick rim of bark at the lower end. The modification consists in trimming away the lower end, as at C; also in paring away part of the flap, as at G. At E is the regular slit; F, the bark opened to receive bud; D, waxed wrapper; H, wrapper tied on. See *Pecan.*



1686. Modified shield-bud.

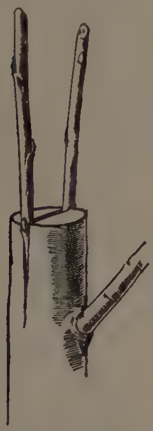
Proper time to bud. (Hedrick.)

Inasmuch as the various kinds of trees used as stocks for budding vary greatly in length of their growing season, it naturally follows that the time during which they may be budded will vary accordingly. In a normal season, the figures for New York are about as follows:

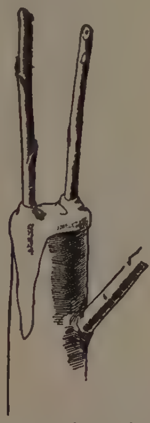
Rose	July 1 to July 10.
Pear	July 10 to July 15.
Apple	July 15 to August 1.
Plum (St. Julien stock)	July 15 to August 1.
Plum (Myrobalan stock)	August 15 to September 1.
Cherry (Mazzard stock)	July 20 to August 1.
Cherry (Mahaleb stock)	August 20 to September 1.
Quince	July 25 to August 15.
Peach	August 20 to September 10.

Grafting.

Grafting proper is the operation of inserting a twig or a woody cion into a stock. They may be classified in respect to the place or position of the cion on the stock:



1687. Cleft-grafting.



1688. The cleft-graft waxed.

1689. Cleft-graft cion.

Root-grafting, or the insertion of the cion in the root of the stock;

Crown-grafting, or the insertion of the cion at the crown (surface of the ground);

Stem-grafting, or the insertion of the cion in any part of the main stem or trunk;

Top-grafting, or the insertion of the cion in the top or branches of the plant.

Grafting may again be classified in respect to the maturity of the cion: dormant wood grafting; and soft-wood or herbaceous grafting, in which the cion is taken from green or growing wood.

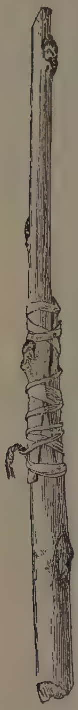
It is customary to classify grafting on the way in which the union is made. There are few general types in common use in this country: as cleft-grafting, whip-grafting, veneer-grafting (side-grafting, bark-grafting).

Cleft-grafting.

Cleft-grafting consists in splitting the stock and inserting a wedge-shaped cion into the cleft. It is employed only in rather large stocks, preferably in those an inch or more in diameter. The stock is cut off, and it is split with a knife or tool made for the purpose. The cleft is then held open by a wedge and the cions are inserted in the side of the cleft in such position that the cambiums of the stock and cion are in contact (Fig. 1687). The whole surface is then securely waxed, to prevent evaporation and to protect the wounds from the sun (Fig. 1688). Cleft-grafting is performed in early spring. The cions are taken some time previously from the last year's shoots. They are stored in a cellar or other cool place in order that they may be perfectly dormant. It is customary to cut them of three buds' length; but if the shoot is very long-jointed and if the variety is new or rare and the wood therefore scarce, they may be made of one or two buds. The wedge-shaped part should be somewhat thicker on the outside so that it may be clasped tightly in the cleft (Fig. 1689). It is customary to have one bud near the top of the wedge. Although this bud is covered with wax, it is the most likely to grow, since it is nearest the source of food-supply and is less injured by external conditions. It pushes through the wax. It is customary to insert two cions in all stocks, even though only one branch is desired. By inserting two cions, the chances of success are doubled, and the wounds heal better if a twig grows on either side. After a year or two, one of the cions may be cut off if desired.

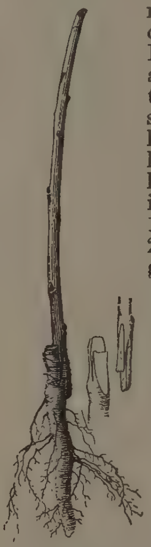
1690. One way of cleft-grafting an old tree.

Cleft-grafting is the method usually employed in the top-grafting of fruit trees, as apples, pears, plums and cherries. Old peach trees are rarely changed over to a new variety. If they are, budding is employed, as already suggested: the limbs are headed back so that new wood is secured in which the buds may be set. It is important, in all top-working of fruit trees, to keep down the suckers which spring up around the cion, and which sometimes completely choke it. In changing over the top of a fruit tree, all the leading branches should be grafted (Fig. 1690). It is well to stand at some distance from the tree and make a mental picture of how the tree will look when the new top is secured: the grafts should be set in approximately a radius from the center of the tree. It is rare that the stock should be larger than 2 inches in diameter where the cions are set. On some of the main branches it may be necessary to graft side branches lower down in order to fill the top and to afford footholds to pickers and pruners. It will require from three to four years to change over a tree in full bearing to a new variety. Each year a little more of the original top is removed, and the cions take more and more of the space.

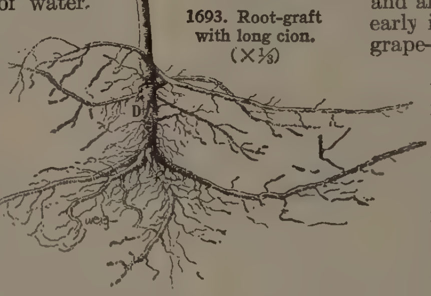


1691. Whip-graft.

Grafting-wax is of many kinds, but the most serviceable for applying with the hands in the open air is made by melting together one pound (by weight) of rendered tallow, two parts of beeswax and four parts of resin. The melted liquid is poured into a pail or tub of water, when it immediately hardens. It is then pulled until it is light-colored and develops a grain. It is then put away for future use, and will keep indefinitely. When the wax is used, the warmth of the hands will cause it to soften. The hands should be greased to prevent it from sticking.



1693. Root-graft with long cion. (×⅓)



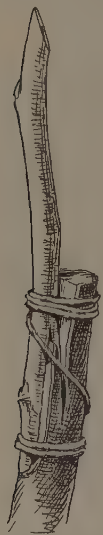
1694. Tree grown from a long-cion root-graft. The union is at D.

For a softer wax, more tallow may be used; or linseed oil may be substituted, but because of adulteration of the oil the results are not always reliable.

Alcoholic waxes, or plastics, are sometimes made, to be applied with a brush or swab; on application, the alcohol disappears and the material hardens. A standard formula (Lefort's) is: best white resin, one pound; beef tallow, one ounce; melt, then remove from fire and add eight ounces alcohol. Keep in tightly closed bottles. Sometimes a teaspoonful of turpentine is added.

Whip-grafting.

Whip-grafting, or tongue-grafting, is employed in the nursery and on very small stocks. It is not used in top-grafting except now and then on small limbs. The cion and stock should be of approximately equal size. Each is cut off in a slanting direction, and a split or tongue is made near the middle. The same shape is given to cion and stock. The pictures sufficiently illustrate how the work is done. (Figs. 1691–1693). The object of the tongue is to hold the parts together securely; it also presents more contact. The cion is then bound to the stock, preferably by means of waxed cord. If the graft is above ground, the wounds should be thoroughly waxed over the string. If the graft is below ground, the tie will be all that is necessary: the moist earth packed around the wound will prevent evaporation and protect it.



1692. Whip-graft, before waxing.

The chief use of the whip-graft is in root-grafting, which is employed largely on apples and mostly at the West. In the East, other things being equal, budded apple trees are preferred to root-grafted trees. In the West, however, it is necessary to have apple trees on roots of known hardiness. The seedling stocks are not of known hardiness, even though the seeds have come from the hardiest varieties. It is therefore customary to use cions 6 to 12 inches long, grafted on pieces of roots 2¼ to 4 inches long. (Fig. 1693.) The graft is set so deep that only the top bud of the cion projects above the surface. The piece of root acts as a nurse, and roots may start from the cion itself. (Fig. 1694.) When the tree is transferred to the orchard, the original root may be cut off in case it is not very vigorous; although this is not done if the union seems to be good and the foster roots are strong. This root-grafting is done in winter (December and January preferred); the grafts are stored in clean sawdust, sand or moss in a cool cellar, and are set in nursery rows in the open early in the spring, after the manner of grape-cuttings.

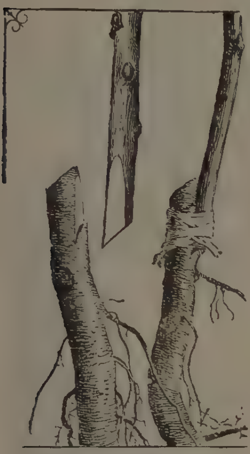
The waxed string, with which the whip-grafts are tied, may be made by dropping a ball of yarn into melted grafting-wax. In five minutes the wax will have penetrated the ball, but the strand can readily be unwound. The best material for this purpose is No. 18 knitting-cotton. This is strong enough to hold the work together, and yet weak enough so that it may be broken in the hands without cutting the fingers. It will ordinarily decay during the year, and thereby not interfere with the growth of the tree. If the grafting is performed in a room at a living temperature, the waxed string should be soft enough to stick to the stock without being tied. Four or five turns are made around the union. Waxed manilla paper, cut in narrow strips, is also used; also single strand cotton "chain" or warp-thread, either waxed or not waxed.

Any sharp knife with a handle large enough to be grasped readily is useful for whip-grafting. The blade should be thin, and the steel of best quality. The handle should also be strong. Fig. 1695 shows a common form of grafting-knife. Good shoe-knives may be used. This and similar knives are in the market. A hone and whetstone should be near at hand, for the edge should be keen.

1695. Grafting-knife. (×½)

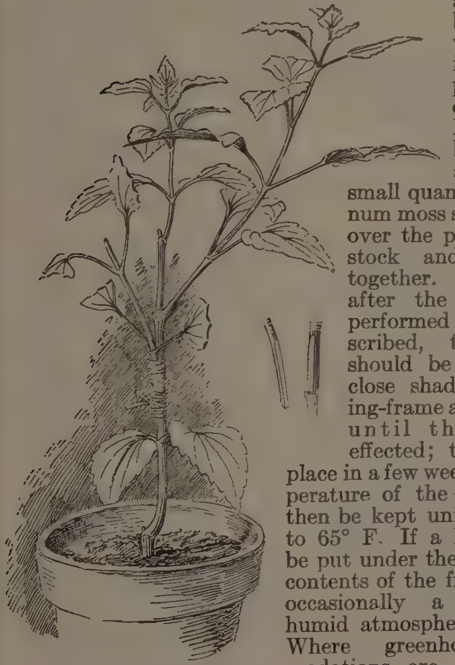
Veneer-grafting.

This style of grafting, which is considerably used under glass with fancy and ornamental plants, consists in simply champering the sufaces of cion and stock and applying the one to the other. (Fig. 1696.) The cion is bound to the stock by raffia or other material. If the graft is in the open, the wounds are thoroughly waxed; but in the house they may be covered merely with moss. This style of union is used with herbaceous plants, as well as on hard wood. Sometimes the stock is severed at the point of union, as in Fig. 1696; but in other cases it is not severed nor headed back until the cion has taken hold (Fig. 1697). In the latter case, the stock is not injured in case the graft does not grow.

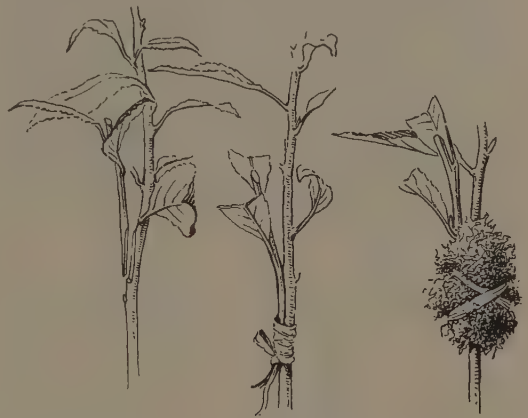


1696. Veneer-grafting.

Writing of the propagation of the tea plant under glass (which is suggestive for other plants in houses), Oliver says: "Seedling stocks may be grown in 4- or 5-inch pots for the reception of cions by the veneer method of grafting. To have the plants in perfect condition for working, it is necessary that they be grown from the seedling stage without a check, as the healthier the plant the better the chance of a successful union. Another important matter in this connection is that the stock plants should not be allowed to form matted roots in small pots; therefore, it will be found better to lift them from the nursery and put them in pots previous to the operation: or they may be grown and grafted while in garden flats. If this last-named method is chosen the plants should be situated far enough apart in the flats to be easily handled. If the grafting is performed while the stocks are in active growth, the union will take place more quickly than when the plants are in a dormant condition. The operation should be performed in the early part of spring. Fig. 1698 shows how the incision in the stem should be prepared. This should be made with a sharp knife and the cut at the deepest part should not be more than one-third of the diameter of the stem. The cion must be shaped at the base so that it will fit neatly into the place prepared for it on the stock. It should then be tied, and afterward a small quantity of sphagnum moss should be tied over the part where the stock and cion come together. Immediately after the operation is performed as above described, the plants should be placed in a close shaded propagating-frame and kept there until the union is effected; this will take place in a few weeks. The temperature of the frame should then be kept uniformly at 60° to 65° F. If a layer of moss be put under the pots and the contents of the frame syringed occasionally a favorably humid atmosphere will result. Where greenhouse accommodations are not available for the propagating-frame a hotbed may be built out-of-doors in a location where the sun will not have much effect in raising the temperature. From 6 to 9 inches of stable litter and leaves will provide ample heat during the spring. When it is found that the cions have made connection with the stocks, air should gradually be admitted to the frames. Shortly after this the tops of the stocks may be cut off close to the cions. Planting out may be deferred till the cions have made their first growth."



1697. Veneer-grafting.

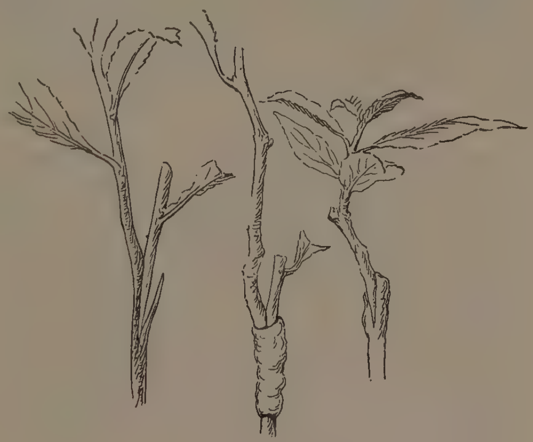


1698. Veneer-grafting.

A form of veneer-graft is what is sometimes called the side-graft. It is shown in Fig. 1699 (adapted from Oliver).

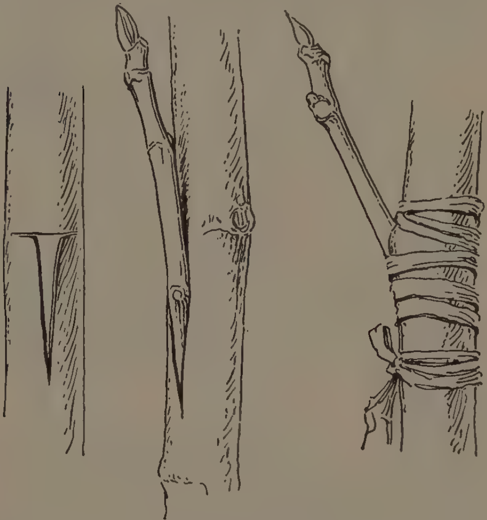
Cion-budding.

When a woody cion is inserted underneath the bark in the side of the stock, as a shield-bud is inserted, the method is sometimes known as cion-budding. In describing a simple way of propagating the fig, Oliver writes: "This method consists of preparing the stock for the reception of the cion as in shield-budding. This is done by making a transverse cut through the bark ¾ inch in length. From the middle of this incision another cut is made toward the main stem or root for fully an inch. The bark is then pried up as seen in Fig. 1700. Instead of inserting a single shield-bud, a small twig having one terminal and one or two lateral buds is used. The cion is prepared as follows: A long scarf is made at one side through the pith and a thin piece of the bark on the reverse side is removed. With



1699. Side-grafting.

the long cut facing the stock the cion is pushed deeply into the place prepared for it, and is tied firmly with raffia. The corners of the bark of the stock are brought close to its own stem and bound firmly in that position. Melted grafting-wax should then be put on, or narrow strips of waxed cloth may be applied instead, to exclude air and moisture. If possible, the cions should be selected from branches not over ½ inch in diameter when they can be found of sufficient firmness of that thickness. Small lateral shoots having a terminal bud and only an inch or two in length and quite thin will unite by this method very easily. It is not necessary for the cions to be dormant, but they should be fully matured and the leaves cut off to about ½ inch from the buds. The bark slips readily from the time growth begins in spring, so that the operation may be performed at any period during late spring and summer. In the course of about two weeks after the operation is performed, if the cions remain fresh, the probabilities are that a union will have been effected. Part of the top of the stock may then be removed to induce the cion to start growth, and when it has made some headway the top of the stock may be cut off near the cion."



1700. Cion-budding.

Bark-grafting.

Bark-grafting (Fig. 1701) is an excellent method of grafting fairly large limbs, since it does not injure the stock so much as does the cleft-graft. The cions are cut thin and inserted between the bark and wood. The bark is securely bound to hold it tight, and the entire surface is waxed, as in cleft-grafting. This method is called crown-grafting by the French and English.

This method is useful when it is necessary to graft very large limbs, for the stub does not need to be split and several cions may be set. When large limbs are broken from apple and pear trees, the stub may be trimmed and several cions set around it, to hasten the healing and to afford strong shoots with which to renew the part.

Herbaceous grafting.

Pelargoniums, chrysanthemums, cacti, and other soft-wooded greenhouse plants are sometimes grafted for the novelty of having more than one variety growing on the same root. Probably most herbaceous plants can be grafted readily, with the exception of the endogens, which do not lend themselves to the operation, although there are examples in which grafting has been successful on them. To succeed with an herbaceous cion, it is necessary that the room be rather close and moist, so that evaporation will not be very rapid. One should endeavor to secure the general conditions that obtain in a good propagating-house. The temperature should be kept rather below the normal for that species until union has taken place. It is usually best to cover the union with moss or some other material to protect the wound and to check evaporation. Best results are secured when the cion is firm in texture, as also in the case of herbaceous cuttings. The kind of graft is of less importance, although it is customary to use the veneer-graft cions, since there is less injury to the stock and the outer surfaces are easily applied to each other. The cion ordinarily consists of one or two joints, and if the leaves are large, they are cut in two, as in the making of softwood cuttings.

1701. Bark-grafting.

Inarching, or grafting by approach.

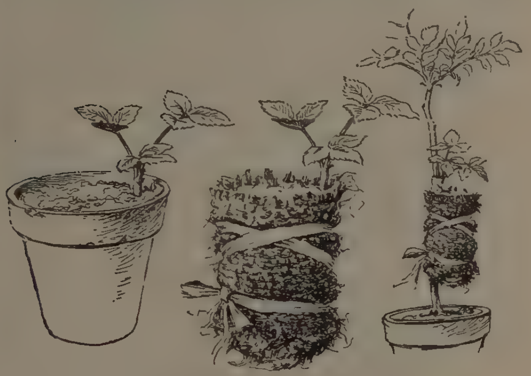
In those cases in which union takes place with much difficulty, it is possible to effect the conjunction by allowing the cion to grow fast to the stock before it is severed from its own roots. The plant which it is desired to have grow on the stock is bent over to the stock, the surfaces of the two are exposed so that the cambiums may be pressed close together, and the two are then bound until union takes place. In some cases a tongue is made in both the cion and the stock, much as in whip-grafting, so that the surface of contact is greater and the parts are held together more securely. When the cion has become thoroughly established on the stock, the cion is severed from its own root and the top of the stock is cut off. This inarching or grafting by approach is also used in the greenhouse when it is desired to transfer the whole top or the whole branch of one plant to another. The illustration (Fig. 1702) shows such a case. Inarching is not much employed in this country in a commercial way.

Inarching is sometimes employed to unite two branches into one for the purpose of making a specimen fruit grow larger. If, for example, a twig of an apple tree is inarched into a limb just back of a fruit, the extra food-supply may cause that fruit to grow larger, and a finer specimen may be secured. This use of the graft is employed only for the purpose of securing extra-fine specimens for exhibition or other purposes.

1702. Inarching the branches of two plants.

The seedling-inarch has recently been described in detail by Oliver (Bull. No. 202, Bur. Pl. Ind., U. S. Dept. Agric.). Such difficult subjects as the mangosteen, litchi and mango respond readily to this method. The idea is to inarch a very young seedling on an older stock, thereby saving time and securing more wood for further propagation. "Seedlings raised from seeds of new and rare trees, shrubs, and vines may be induced to grow very quickly if used as cions when a few weeks old by inarching to strong-growing plants of other species of the same genus or in some cases on species of other genera of the same family. This has been done recently with such plants as chestnuts, walnuts, hawthorns, oaks, and many others. It is not necessarily done for the purpose of hastening the flowering or the fruiting of new plants, but to give quickly an abundance of material for propagation by budding or grafting when the new material is assumed to be valuable. If a hardwood seedling of hybrid origin is tied to a large stock and they fail to unite, there is little or no danger of losing the seedling, provided its roots are kept damp during the period of making the attempt. If the inarch is not successful, the seedling can be repotted and grown in the usual way."

In Fig. 1703 is shown the method of seedling-inarch. A rose seedling is grown near the side of a pot, it having been pricked off into a 2-inch pot shortly after the cotyledons are developed; it is next shown, after two or three weeks' growth, removed from the pot and tied in a cloth to facilitate handling, a little fresh soil being held in place by the covering; the ball is then secured to the stock, and the seedling is inarched by chamfering the surfaces in contact. When union is complete, the root of the seedling is removed.



1703. Seedling-inarch of the rose.

Literature.

For further discussion of the whole subject of grafting, the reader is referred to current works on fruit-growing; also to the two American special books on the subject—Fuller's "Propagation of Plants" and Bailey's "Nursery-Book." In English, Baltet's "Budding and Grafting" is standard. It is an English version of "L'Art de Greffer." L. H. B.

GRAHÀMIA (Robert Graham, Scotch botanist, died 1845). Two genera have been made of this name. The accepted one is of the Portulacaceæ, comprising one species (*G. bracteata*, Gill.) of extra-tropical South America; this plant is not recorded in cultivation. The other Grahamia (of Sprengel) is now referred to Cephalophora; and Cephalophora is by Hoffmann (Engler & Prantl, Pflanzenfamilien, iv:5) included in Helenium. Of this Grahamia, *G. aromatica* is offered abroad; it is accounted for under *Helenium*.

GRAMMÁNGIS (Greek, *gramma;* perhaps referring to the markings of the flowers). *Orchidàceæ*, tribe *Vándeæ*. Epiphytic orchids grown in greenhouses.

Pseudobulbs short and thick, with foliage-lvs. only at their summit, hence not inclosed in the lf.-sheaths: fl.-clusters from the base, many-fld., pendulous; fls. not spurred; middle sepals strongly concave, lateral sepals somewhat sac-shaped at base, free, spreading; petals ascending, somewhat different in form and color; lip 3-lobed, with erect lateral lobes and recurved middle lobe; column slender, winged.—Species about 4, of Madagascar and Java. Nearest Cymbidium, differing chiefly in having the foliage-lvs. only at the end of the pseudobulb, and the rostellum crescent-shaped (in Cymbidium it is triangular). From Grammatophyllum (which see), Grammangis differs in the attachment of its pollen-masses and in the position of its foliage-lvs. Best cult. in baskets hung near the glass, where the light is most intense. The plants can also be grown successfully in pots placed near the glass, or fastened to blocks, but in the latter case they must be given more water.

Éllisii, Reichb. f. (*Grammatophýllum Éllisii*, Lindl.). Pseudobulbs 7–11 in. long, each bearing 5–6 lvs.: lvs. 1½–2 ft. long: sepals yellow, elegantly marked with dark transverse lines; petals and lip pale pink, the latter with a strong mid-nerve. Summer. Madagascar. B.M. 5179. C.O. 2.

G. Húttonii, Benth. & Hook. (Cymbidium Huttonii, Hook. f.). Pseudobulbs of a single internode, 3–5 in. long, elongated, obovoid, green: lvs. in pairs, 6–8 in. long, 2–2½ in. wide, dark green, coriaceous: raceme about 10-fld., drooping; sepals obovate, recurved, light brown outside, streaked transversely inside with chocolate-color; lip greenish, with chocolate stripes. June. Java. B.M. 5676. O.R. 14:153. G.M. 48:467. G.C. III. 38:63.

T. H. Kearney.

GRAMMÁNTHES (Greek, *letter-flower;* the petals of the full-colored varieties have a darker mark like a letter V, whence also the name of the synonymous genus *Vauanthes*). *Crassulàceæ*. One small very variable half-hardy, succulent annual, with thick fleshy leaves and yellow flowers, growing about 6 inches high and is used for edgings, baskets and pots.

Erect, forking: calyx bell-shaped, semi-5-fld.; corolla-tube as long as the calyx; limb 5–6-lobed: carpels 5–6, many-ovuled, with awl-shaped styles: scales minute, or evanescent: follicles many-seeded. In sandy ground in the western part of the Cape region, S. Afr.

dichótoma, DC. (*G. gentianoìdes*, DC.). Glabrous, somewhat glaucous: branches forking: sts. rigid, filiform: lvs. opposite, distant, oblong, ovate or nearly linear: fls. orange, yellow, or creamy white, and marked as above described. F.S. 5:518. Var. **vèra**, (Harv.), has lvs. ovate-oblong: limb of corolla ovate-oblong, a third longer than the stamens. Var. **chloræflòra,** (Harv.), has lvs. oblong or linear: fls. a little larger; limb of corolla ovate-lanceolate, twice as long as the stamens. B.M. 4607, 6401. There are other named forms. Some of them are very depauperate in their native region, some of them only 1–2 in. high. Wilhelm Miller.

GRAMMATOCÁRPUS: *Scyphanthus.*

GRAMMATOPHÝLLUM (Greek, *gramma*, a line or streak, and *phyllon*, leaf; probably referring to the parallel leaf-veins). *Orchidàceæ*, tribe *Vándeæ*. A group of perhaps 8 or 9 epiphytic species, of which about half are well-defined, inhabiting the islands from Madagascar to the Philippines and New Guinea. The genus includes some of the largest and showiest of cultivated orchids.

Roots numerous: sts. or pseudobulbs many-lvd.: lvs. long, ribbon-shaped, thick, evergreen: racemes long-stalked, loosely many-fld., springing from near the base of the pseudobulb; fls. large, not obviously spurred; sepals and petals nearly equal, spreading; lip comparatively small, with margin entirely free, 3-lobed, with erect lateral lobes; column slender. Allied genera are Grammangis and Cymbidium, from both of which Grammatophyllum differs in having the pollen masses each borne upon an appendage of the stalk, while in the two related genera they are attached to a common stalk without special appendages.

The few species in cultivation are such infrequent bloomers that the flowering of a fine example is something of an event. They are propagated from pieces of the pseudobulbs. The plants are best grown in good-sized and well-drained pots filled with peat, and need considerable water while actively growing. They should be allowed to rest occasionally. Season of bloom and further cultural details with each species.

A. *Pseudobulbs very long, comparatively slender.*

speciòsum, Blume (*G. Sanderiànum*, Hort.). LETTER PLANT. Fig. 1704. Pseudobulbs 6–10 ft. long, slender, flexuous: lvs. 2-ranked, 1–2 ft. long: fl.-clusters open, sometimes 6 ft. long from the base of the stalk; fls. numerous, 6 in. diam., clear yellow, spotted with deep red purple. Winter. Malayan region, notably Java. G.C. III. 7:297; 13:1; 22:145, 147; 33:391; 40:86; 42:169, 170. B.M. 5157.—This magnificent plant, one of the very largest of its family, has been well-named the "queen of orchids." A huge individual growing on a tree in the open at the Botanical Garden of Buitenzorg, Java, has the following dimensions: diam. of whole plant, 18 ft.; collar about the trunk of the tree formed by the closely interwoven roots, 7½ ft. diam., 2½ ft. thick, and over 3 ft. high; fl.-clusters (appearing at the same time) 50–60, each 2 ft. or more in length and bearing 70–100 fls. And it must be remembered that this huge plant is an epiphyte! Temperature, especially soil temperature, should be carefully regulated in growing this plant. Owing to the brighter light, it does better in American than in European hothouses.

1704. Grammatophyllum speciosum.

AA. *Pseudobulbs comparatively short and thick, leafy only at summit.*

B. *Fls. greenish or yellowish, spotted with brown.*

Fenzliànum, Reichb. f. (*G. Measuresiànum*, Hort.). Lvs. 4–6: fl.-clusters sometimes 15 at one time, each over 5 ft. long and containing over 60 fls., sepals and petals narrow, greenish yellow, tipped and spotted with brown; lip streaked with purple. April. Isl. of Amboina, Philippine Isls.(?). J.H. III. 29:123. G.M. 34:334. Var. **Measuresiànum**, Hort. (*G. Measuresiànum*, Hort.). Fls. larger and brighter; sepals and petals emerald-green, marked with brown-purple. G.W. 2, p. 73.

Rumphiànum, Miq. (*G. Guilélmi II*, Kränzl.). Pseudobulbs 6–8 in. long, ovoid or fusiform: lvs. 1–2 ft. long: raceme nodding or hanging, 3–4 ft. long from the base of the stalk; fls. often 30–35, 3 in. diam., green outside, green blotched with brown-purple within; sepals and petals similar; lip purple-veined, downy. Molucca Isls., Borneo, New Guinea, and the Philippines(?). B.M. 7507. C.O. 1.—A large, showy species.

BB. *Fls. brown, streaked with green.*

multiflòrum, Lindl. Lvs. 3–4: fl.-clusters nearly 2 ft. long. Summer. Philippine Isls. P.M. 6:217.—This very desirable species has not yet found its way into American trade. It is easily grown, either in a pot filled with a well-drained "compost of heath soil and potsherds," or merely fastened to copper wire and hung from the roof.

G. Éllisii, Lindl.=Grammangis Ellisii.—*G. indeterminàle*, Hort. =(?).—*G. levíctum*, Hort.=(?).

T. H. KEARNEY.
GEORGE V. NASH.†

GRAPE. Plants of the genus Vitis, and the berries thereof, abundantly grown for fruit.

The grape is one of the oldest of domesticated fruits. It is probable that wine was made from it before the plant was brought into cultivation. It seems to have been cultivated at the dawn of history. Its product was apparently no rarity in Noah's time.

The grape of history is the Old World *Vitis vinifera*, the "wine-bearing Vitis," probably native to Asia. The paramount use of the grape always has been the production of wine. A secondary value is the production of raisins; and another is fruit for the dessert and for culinary uses. Great efforts were made to introduce the cultivation of the European grape into the American colonies, but they resulted in failure. It was not until the latter part of the last century that the chief causes of this failure became known: the depredations of the phylloxera and mildew,—and even then the causes were discovered largely because these American parasites had made incursions into the vineyards of Europe. In the meantime, one or two of the native species of Vitis had been ameliorated, and American viticulture had become established on a unique and indigenous basis, and the fruits are grown to eat rather than to drink. So fully did these early American ventures follow European customs that the grapes were usually planted on terraced slopes, as they are on the Rhine and about the continental lakes. Those early experiments finally failed because of the black-rot.

North America is richest in species of Vitis (see the article *Vitis*). These species range from ocean to ocean and from the British possessions to the tropics. The species that has been most improved is *Vitis Labrusca* of the Atlantic slope, although it seems to possess less native merit than some of the southwestern species-

1705. The Labrusca or Fox-Grape type. Niagara (at left); Brighton.

types. Of this species are the Concord and Catawba types (Fig. 1705). To some extent it has been hybridized with *Vitis vinifera* (as in Agawam, Lindley, Barry, and others of E. S. Rogers' varieties), and with native species. Already a number of the popular varieties represent such wide departures that they cannot be referred positively to any species. Of these, Delaware and Isabella are examples. The second most important species, in point of amelioration, is *Vitis æstivalis*, from which several of the best wine grapes have sprung (Fig. 1706). The post-oak grape (*Vitis Lincecumii*, or *V. æstivalis* var *Lincecumii*) of the Southwest, is one of the most promising species, and already has given excellent results in hybridization. See Fig. 1707. The Muscadine (*V. rotundifolia*) of the South has given the Scuppernong and a few less known forms. (Fig. 1708.) Beyond these species, there are none which has given varieties of great commercial importance, although considerable has been done in improving them. Some of the best of the wild species are practically untouched; there is only a comparatively small area of our great country which has yet developed large interests in grape-growing: the grape-types of a century hence, therefore, may be expected to be very unlike the present-day varieties. For an extended sketch of American grape history, see Bailey, "Evolution of Our Native Fruits" (1898). The American grape literature is voluminous. More than fifty authors have written on the subject. Yet there is very little of this writing which catches the actual spirit of American grape-growing; this fact, together with the technicality and diversity of the subject itself, makes it seem wise to devote considerable space to the grape in this Cyclopedia.

1706. Horticultural product of Vitis æstivalis—Onderdonk, seedling of Herbemont. (×⅝)

While the native grape was being ameliorated in the East, the Old World *Vitis vinifera* was becoming established on the Pacific slope. In fact, *Vitis vinifera* has there run wild. The phylloxera and mildew are not native there, and the climate better suits the species. The Pacific coast viticulture, therefore, is of the Old World kind.

We now know that the phylloxera or root-louse can be evaded when the vinifera grape is grafted on native or resistant stocks, and the mildew can be combated by fungicides. Of late years, therefore, new efforts have been made to grow the wine grape in the eastern states, and in the southern latitudes some of these experiments promised well for a time. However, so great attention is required to produce a satisfactory product as to discourage the growing of vinifera varieties in the open in the East. Vinifera types will always be special grapes in the East, adapted only to particular conditions, for it is not to be expected that they can compete with the more easily grown and cosmopolitan varieties of the native species. Under glass, however, the vinifera varieties thrive; and a special discussion is given herewith (page 1388) to this branch of the subject.

The greatest development of the native grape industry has taken place in Ontario, New York, and Ohio, bordering lakes and large streams. These areas are the lower Hudson River Valley; the region of the central-western New York lakes; the Lake Erie region of New York, Pennsylvania and Ohio; the so-called peninsular region of Ontario lying between Lake Erie and Lake Ontario. There are also important grape interests in Michigan, and other northern parts. There is considerable interest in grape-culture in the cooler parts of Georgia and Alabama, and there are enlarging areas in the country extending from the Ozark region southward. Nearly all the country, excepting the northernmost parts, raises grapes, but in most cases the growing of them cannot be said to be extensive enough to be called an industry. Although the grape sections of the North follow the water areas where the land is often steep, all grape-growers prefer nearly level land. The Old World plantations are largely on very steep lands; such lands, by virtue of their warmth and drainage, are thought to give an extra quality of wine. These ideas were brought to this country, and many of our early vineyards were planted on terraced slopes. But we grow grapes for a different purpose from the Europeans, and land is cheap and labor is dear. Old World

1707. Hybrid of Vitis Lincecumii and a fox-grape derivative—Husmann. (×⅝) methods cannot be followed in the American commercial plantations.

The cosmopolitan American grape, of the native type, is the Concord, which originated with Ephraim W. Bull, of Concord, Massachusetts (Fig. 1709.) Other varieties of leading prominence in the North are Catawba, Delaware, Niagara, Worden.

1708. The Muscadine grape.—Vitis rotundifolia.

The ideal bunch of grapes is of medium size for the variety, compact, uniformly developed and ripened throughout, containing no small or diseased berries, and with the bloom intact. A very dense or crowded cluster is not the most desirable, for all the berries cannot develop fully, and the cluster is not easily handled when the fruit is eaten. Fig. 1710 shows a cluster of good shape and compactness: Fig. 1711 is too broad and irregular; Figs. 1712, 1713, are rather too dense and compact.

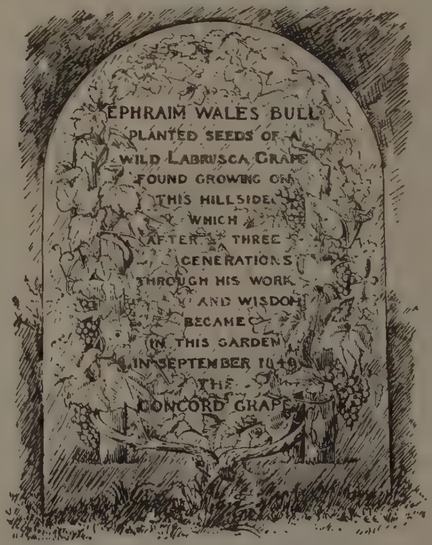
The American grape is essentially a dessert fruit. It is eaten from the hand. There are several manufactured products, but, with the exception of wine, they have been of minor importance until recent years, although there are many large wine-cellars in New York and Ohio, and the product is of excellent quality. Unfermented grape juice is now manufactured in great quantities and has become an important article of commerce (see Cyclo. Amer. Agric. Vol. II, p. 178). The lack of secondary domestic uses of the grape has been one reason for the very serious gluts in the markets. However, one year with another, the profit on a good vineyard may be expected to exceed that on the staple farm crops.

Pruning and training.

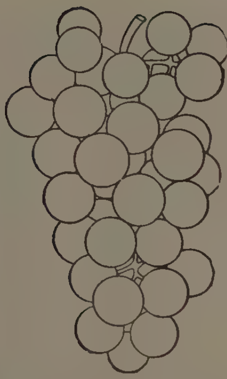
A grape-vine is pruned in order to reduce the amount of wood (that is, to thin or to limit the amount of fruit), and to keep the plant within manageable shape and bounds. A vine is trained in order to keep it off the ground, out of the way of the workmen, and so to arrange the fruit that it will be well exposed to light and air. In order to understand the pruning of grapes, the operator must fully grasp this principle: *Fruit is borne on wood of the present season, which arises from wood of the previous season.* To illustrate: A growing shoot, or cane of 1914, makes buds. In 1915 a shoot arises from each bud; and near the base of this shoot the grapes are borne (one to four clusters on each). This is shown in Fig. 1714. The 1914 shoot is shown at the top. The 1915 shoot bears four clusters of grapes. While every bud on the 1914 shoot may produce shoots or canes in 1915, only the strongest of these new shoots will bear fruit. The skilled grape-grower can tell by the looks of his cane (as he prunes it, in winter) which buds will give rise to the grape-producing wood the following season. The larger and stronger buds usually give best results; but if the cane itself is very big and stout, or if it is very weak and slender, he does not expect good results from any of its buds. A hard well-ripened cane the diameter of a man's little finger is the ideal size.

The second principle to be mastered is this: *A vine should bear only a limited number of clusters,*—say from thirty to eighty. A shoot bears clusters near its base: beyond these clusters the shoot grows into a long, leafy cane. An average of two clusters may be reckoned to a shoot. If the vine is strong enough to bear sixty clusters, thirty good buds must be left at the annual pruning. How much a vine should be allowed to bear will depend on the variety, distance apart of the vines, strength of the soil, age of the vine, system of pruning, and the ideals of the grower. The Concord is one of the strongest and most productive of grapes. Twelve to fifteen pounds is a fair crop for a mature vine; twenty pounds is a heavy crop; twenty-five pounds is a very heavy crop. An average cluster of Concord will weigh one-fourth to one-third of a pound. The vine may be expected to carry from thirty to sixty clusters; and the annual pruning will leave from fifteen to thirty buds.

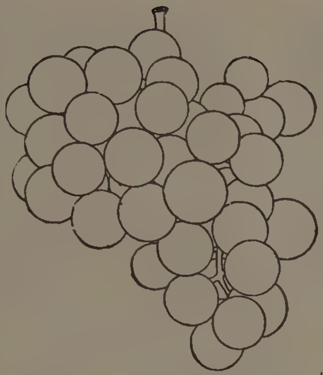
Since the bearing wood springs from new canes, it follows that the fruit of the grape is each year borne farther from the main trunk of the vine. Observe that the fruit of wild vines is borne beyond reach when they climb over thickets and trees. It is a prime object of the grape-grower to obviate this difficulty. The third principle in the pruning of grape-vines is this: *The bearing wood should be kept near the original trunk or head of the vine.* When one cane is sending out fruit-bearing shoots, another shoot is taken out from near the main trunk or head to furnish fruit-bearing shoots for the next year; and the other or older cane is entirely cut away after the fruit is off. That is, the wood is constantly renewed; and the new shoots which are to give bearing wood the following year are called *renewals.* Some systems of grape-training renew back to the root every year or two, and these have been called renewal systems; but every system of grape-pruning must practise renewal in one way or another.



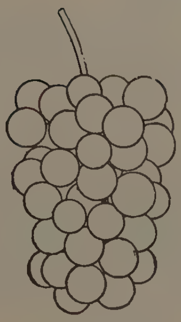
1709. Monument to the Concord grape and Ephraim W. Bull. Erected by the town of Concord.



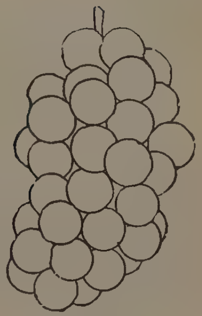
1710. Grein Golden. A good grape cluster.



1711. Eaton.



1712. Moore Early.

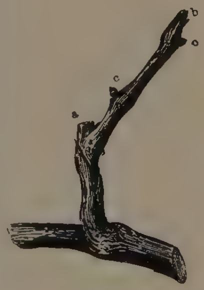


1713. Massasoit.

An old system of renewal was by means of spurs. Fig. 1715 illustrates this. The horizontal part is a permanent arm or branch. We will suppose that it grew in 1912. In 1913 a shoot grew upward. It bore two or three clusters of fruit. In autumn it was cut back to *a*, two buds being left to supply the shoots of the succeeding year. This short branch is now called a *spur*. Only one shoot was wanted for the next year, but two buds were left in case one should be injured. In 1914, a branch grew from one of these buds: it bore fruit: in the fall it was cut back to *b*. In 1915 a shoot will grow from one of the buds, *c*. Thus the spur elongates year by year, becoming a forking, complicated, stubby branch. After a few years it may become weak: the grower sees this, and if a new shoot should start from the main arm near the base of the spur, he encourages it and cuts off all of the old spur: thus he renews back again to the main vine. Shoots from adventitious or secondary buds are likely to spring from the main arm or the spur at any time. These are usually weak and are removed, but now and then a strong one arises. Spur-pruning is now rarely used except in grapes grown on arbors or under glass, in which cases it is necessary to have a long, permanent trunk. On arbors it is best to carry one arm or trunk from each root to the top of the framework. Each year the lateral canes are cut back to spurs of two or three buds. The pruning of glasshouse grapes is discussed under *Grapes under glass* (page 1389).

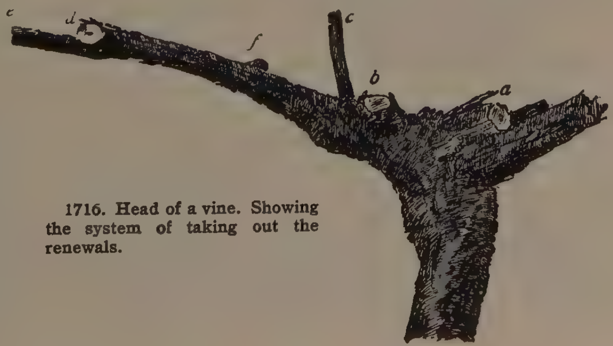
1714. Fruit-bearing of the grape.

The current systems of pruning renew to a head—or to the main trunk—each year. The trunk is carried up to the desired height—to one of the wires of the trellis—and one or more canes are taken out from its top each year. The object is to keep the bearing wood near the main trunk and to obviate the use of spurs. This type of pruning is illustrated in Fig. 1716. This engraving shows the head of a vine seven years old, and on which two canes are allowed to remain after each annual pruning. The part extending from *b* to *f* and *d* is the base of the bearing cane of 1914. In the winter of 1914–15, this cane is cut off at *d*, and the new cane, *e*, is left to make the bearing wood of 1915. Another cane arose from *f*, but it was too weak to leave for fruiting. It was, therefore, cut away. The old stub, *b*, *f*, *d*, will be cut away a year hence, in the winter of 1915–16. In the meantime, a renewal cane will have grown from the stub *c*, which is left for that purpose, and the old cane, *b d*, will be cut off just beyond it, between *c* and *f*. In this way, the bearing wood is kept close to the head of the vine. The wound *a* shows where an old stub was cut away this winter, 1914–15, while *b* shows where one was cut off the previous winter. A scar on the back of the head, which does not show in the illustration, marks the spot where a stub was cut away two years ago, in the winter of 1912–13. This method of pruning can be kept up almost indefinitely, and if care is exercised in keeping the stubs short, the head will not enlarge out of proportion to the growth of the stock or trunk.



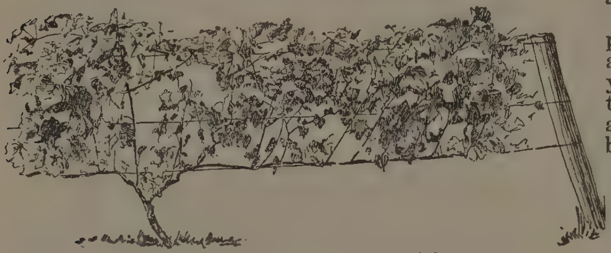
1715. Pruning to a spur.

Two common styles of training are in use in the



1716. Head of a vine. Showing the system of taking out the renewals.

northern states, but each of them practises essentially the system of renewals described in the last paragraph. One style of training carries the trunk only to the lowest wire of the trellis. The canes—usually two in number—are tied horizontally on the bottom wire, and the bearing shoots are tied, as they grow, to the two wires above (Fig. 1717). This is an *upright system*. The other style carries the trunk to the top wire. The canes are tied on the top wire, and the bearing shoots hang. This is the *drooping* or *Kniffin system*. If the shoots run out on the top wire by clinging to it by tendrils, they are torn loose, so that they will hang: this is a very necessary practice. There is controversy as to the comparative merits of these systems, which proves that each has merit. It is probable that the upright system is better for the slender or shorter varieties, as Delaware, and also for those whose shoots stand erect, as Catawba. The Kniffin has distinct merit for strong-growing varieties, as Concord; it is also cheaper, since it requires no summer tying. This system is well illustrated (as given by E. W. Williams in "Garden and Forest," I: 461) in Figs. 1718–1720.

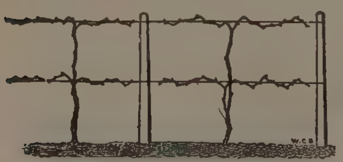


1717. Upright system of grape-training.

At the winter pruning, all the top will be cut away except two canes near the center; these two will be laid down in opposite directions on the bottom wire for the next season's fruiting.

One- or two-year-old vines are planted either in the fall or early spring. At planting, the vine is cut back to three or four buds, and the roots are shortened (Fig. 1724). If all buds start, the strongest one or two may be allowed to grow. The canes arising from this bud should be staked and allowed to grow through the season; or in large plantations the first-year canes may be allowed to lie on the ground. The second year this cane should be cut back to the same number of eyes as the first year. After growth begins in the second spring, one of the strongest shoots should be allowed to remain. This cane may be grown to a single stake through the second summer. At the end of the second year the cane may be cut back to the bottom wire of the trellis, if upright training is to be employed. The cane may be strong enough at this time to be made the permanent trunk of the Kniffin training, but in most cases the trunk is not carried to the top wire until the third year.

The main pruning is performed when the vine is dormant. The ideal time is January and February in the North, although the work is often begun in November if the area is large. Pruning in spring causes the vine to bleed, but bleeding is not injurious. But late pruning interferes with tillage, and the buds are likely to be injured after they are swollen. Summer pruning is now practised only to the extent of pulling out suckers and weak shoots, and even this is not always done. Heading-in the vine in summer is likely to start side growths, which are useless and troublesome.

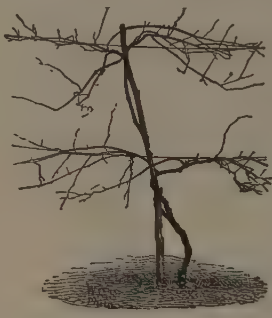


1718. The Kniffin system of grape-training.

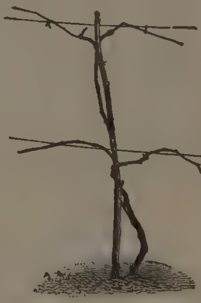
Propagation.

The grape grows readily from seeds, which may be kept over winter and germinated in the house early in the spring. They may even be planted in beds in the open, but the proportion of failures will be greater. Seeds produce new varieties, and they are used only in an experimental way.

The commercial propagation of grapes is accomplished by means of hardwood cuttings. These cuttings are taken in the winter from the trimmings of vineyards. In all ordinary cases they are made of two or three buds' length, preferably three (Fig. 1721). They are cut as soon as the canes are trimmed, tied in small bundles, and these bundles are then buried half their depth in damp sand in a cool cellar. By spring the cuttings will be more or less callused. The cuttings are planted in the open on the approach of warm weather. A loose loamy soil is chosen, and it is well and deeply prepared. The cuttings are inserted until only the upper bud stands at the surface of the ground. These cuttings are placed 6 to 8 inches apart in rows, and the rows are far enough apart to allow of horse cultivation. These cuttings may give plants large enough for sale the following autumn; but it is usually preferred to let the plants grow two years before they are put upon the market. In such cases it is customary in many of the best nurseries, to transplant at the end of the first season. When wood is scarce, the canes are sometimes cut to single eyes. In this case about an inch of wood is left on either side of the bud. Single-eye cuttings are nearly always started under glass, preferably on the greenhouse bench. If they are started in February, they will be large enough for transplanting in a well-prepared seed-bed very early in the spring. Greenwood cuttings are sometimes used in the summer with new and rare varieties, but they are not in general favor. In California, rooted vines of one year are preferred; and in soil in which cuttings root readily, they are sometimes planted directly in the vineyard.



1719. The Kniffin vine before pruning.



1720. The vine after pruning.

The grape is easily grafted. Because of the flexible nature of the vine, however, it is customary to make the graft below the surface of the ground. An ordinary cleft-graft is usually employed. The whole vine is cut off 4 or 5 inches below the surface, and the graft is inserted in the same fashion as in apple or pear trees. The surface may then be waxed or covered with clay or other material, to keep the water out of the cleft, although if the earth is firmly packed around the graft and no water stands, the union may be perfectly satisfactory without any cover. (Figs. 1722, 1723.) Vines of any age may be grafted. It is important that the cions be perfectly dormant. These cions are taken and stored in the same way as cuttings. The grafting should be done very early in the spring, before the sap starts. Grafting may also be performed late in the spring, after all danger of bleeding is over; but, in that case, it is more difficult to keep the cions dormant, and the growth is not likely to be so great the first season. Vineyards composed of unprofitable varieties may be changed to new varieties very readily by this means. Vinifera varieties can also be grafted on our common phylloxera-resistant stocks by the same method. Almost any method of grafting can be employed upon the grape-vine if the work is done beneath the surface.

1721. Common 3-bud cutting of grape.

Insects and diseases.

The grape is amenable to many insect and fungous attacks. The most serious difficulty is the phylloxera, which, however, is practically unknown as an injurious pest on the native grapes. On the vinifera varieties it is exceedingly serious, and it is working great devastation in many of the vineyards of the Old World and of the Pacific coast. The most practicable means of dealing with this pest is to graft the vinifera vines on native or resistant roots.

The mildew and black-rot are the most serious of the fungous enemies in the central and eastern parts of the continent. Both these diseases cause the berries to decay. They also attack the leaves, particularly the mildew, causing the leaves to fall and preventing the grapes from maturing. It is the mildew that has worked such havoc in European vineyards. The mildew is most serious on thin-leaved and smooth-leaved varieties, as the Delaware. It produces yellowish patches on the leaves, with frost-like colonies on the under sides. It causes the berries to decay with a gray and finally a brown rot, the berries usually remaining small and firm but not greatly wrinkled. The black-rot causes the berries to become very hard, dry and shriveled, and the epidermis is covered with minute pimples. (Fig. 1286, Vol. II.) The treatment for both these diseases is the same—spraying with bordeaux mixture. In regions in which the diseases have not been very prevalent, it is usually sufficient to begin the spraying after the fruit has begun to set, and to spray two or three times, as the case seems to require. When the diseases have been very prevalent, however, it may be well to begin before the buds swell in the spring. In infested vineyards, the foliage and diseased berries should be raked up and burned in the fall.

The anthracnose or scab (*Sphaceloma ampelinum*) is a very serious fungous disease. It is most apparent on the fruit, where it makes a hard, scabby patch. Its most serious work, however, occurs on the stems of the clusters and on the young growth, where it makes sunken, discolored areas, and where it interferes seriously with the growth of the parts. It is not so easily controlled as the mildew and the black-rot. Careful attention to pruning away all the diseased wood and burning it will help in controlling the disease. Before growth starts, spray the vines, trellis and posts with sulfate of iron solution. After the leaves open, use the bordeaux mixture.

In grape-houses the powdery mildew (*Uncinula spiralis*) often does much damage. It also occurs in the open vineyard, but it is usually not serious there. It appears as a very thin, dust-like covering on the leaves. It sometimes attacks the berries, causing them to remain small or to crack. This fungus lives on the surface, and is therefore readily controlled in grape-houses by dusting with flowers of sulfur or by the fumes of evaporated sulfur.

The oidium is the most prevalent fungous disease in California. It is controlled by dust-sprays of sulfur (page 1387).

Many other insects and diseases prey upon the grape, but those mentioned above are widespread and may be considered as perhaps the standard parasites. (See Vol II, pp. 1031, 1053.)

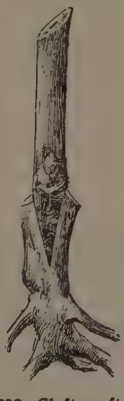
Literature.

The American book literature of the grape is nearly as large as that of all the tree-fruits combined. Probably 100 books, counting the various editions, have been published in North America since Adlum's volume in 1823 (see "Evolution of Our Native Fruits," pp. 117–126). The earlier books were founded largely on European practices. The leading current works are: "Bushberg's Descriptive Catalogue and Grape Growers' Manual;" Mitzky's "Our Native Grape;" Fuller's "Grape Culturist;" Husmann's "American Grape Growing and Wine Making." For the Pacific slope, Husmann's "Grape Culture and Wine Making in California," Wickson's "California Fruits," and Eisen's "Raisin Industry" are useful guides. Detailed discussions of pruning and methods of training are contained in "The Pruning-Book." A standard European monograph is Foëx's "Cours Complet de Viticulture." The recent standard American works are Munson's "Foundations of American Grape Culture," and Hedrick's "Grapes of New York," which are notable contributions to horticultural literature. L. H. B.

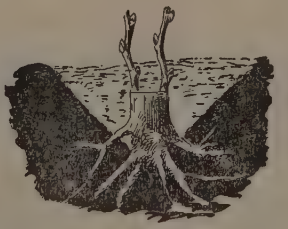
Grapes in the North (Canada).

Any section in which grapes will thrive without winter protection may be said to be a commercial section. For home use they are grown far north by covering with earth or litter during the winter. When the leaves are falling or have fallen in autumn, the vines are pruned—fan system, with the old stalks very close to the ground, and laid flat upon the earth. Here they are left under their straw or earthy covering until danger of frost is past, the following spring, when the covering is removed and the canes tied to the wires. But this is expensive and the method is not commercial.

For market purposes, grapes are grown with one of two main objects in view: either for wine (sweet or fermented) or table and dessert purposes. The purpose determines the variety. Concords and varieties approaching it in type and quality are the choice for the former purpose, while for the latter the variety is determined by the season and the market demand. In the former case, also, the number of varieties is limited, while in the latter they are numerous, ranging from the earliest, Champion, to the latest, Vergennes, and intermediate varieties of all colors and grades.

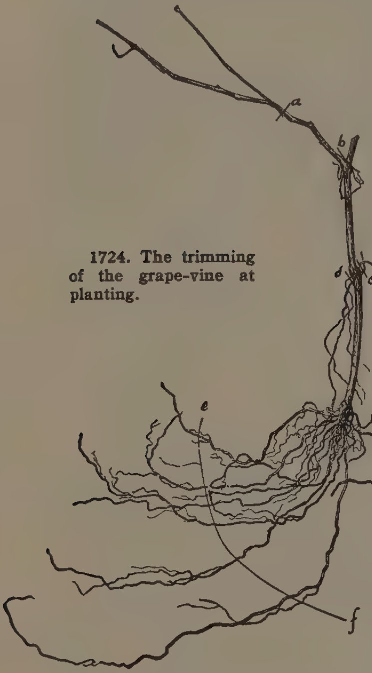


1722. Cleft-grafting the grape.



1723. Cleft-grafting the grape.

Grapes, unlike peaches and cherries, are not subject to very great fluctuations in price and yield. They are comparatively steady in their returns, and, while never advertising themselves by enormous yields and profits, are ever pushing to the front in acreage, yield to the acre and importance. The acreage increase has been very rapid until now New York, the leading northern state of the United States, which thirty-five years ago had but a small acreage, today has more than 70,000 acres, and Ontario, the leading province of the Dominion, has approximately 14,000 acres. The rapid increase has not been because of high prices, but rather steady average prices from $18 to $30 a ton, delivered at the winery, or an equal price f.o.b. the shipping-station. The average yield has not been over two tons to the acre, but, under good conditions, with intelligent management, an average of four to six tons is not uncommon.



1724. The trimming of the grape-vine at planting.

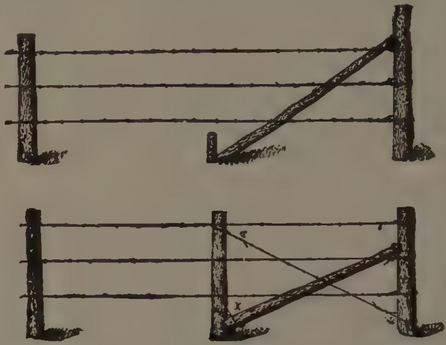
Soils and location.

Grapes are grown on all types of soils, on many sites, in various locations. But the loams and clays with good drainage, the sites with good air-circulation, and the locations that are reasonably free from frost are preferred. Quality is to a large extent determined by soil. Some of the wineries will accept only fruit that is grown on clay soils. The product is more uniform, it ripens more regularly and the sugar-content is higher. Also some coöperative companies that are catering to a special trade, advise their members to plant only on heavy soils because the grapes are sweeter and of higher quality. The ideal soil, however, is the rich, deep, alluvial, easily drained loams that have taken centuries to build up from the washing of the hillsides toward the margins of the lakes and rivers.

The site is of importance for two reasons, those of air-circulation and sunlight, both of which serve the same purpose: to assist the grower in his fight against disease. Disease can live only in conditions that favor it, and light and air are its hereditary enemies. Site is also often discussed with reference to early bud-development and late spring frosts, but its importance has been overdrawn. The number of vineyards injured annually in this manner in the commercial districts is very small.

1725. A vineyard in its first summer.

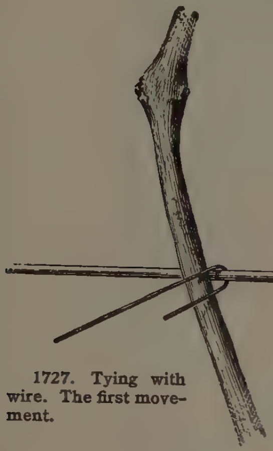
Location (and by that is here meant the situation of a district) is of extreme importance. In the Niagara Peninsula, Ontario,—the largest grape-growing center in Canada,—the aspect is north, with a hill in the rear, and facing the waters of Lake Ontario. Here the crop naturally varies, but it never fails. The same applies to the best parts of New York State, the commercial sections of the one being but continuations of the other. The favored spots in Ontario are not on the shore of the lake but rather just below the escarpment where the water has less influence. Grapes on the shore sometimes fail to ripen well and the quality is consequently inferior. Because of this, many vineyards on the shore have been removed in late years, while the interior plantings have largely increased. If the volume of water were smaller, the influence would be sufficient only for frost-protection; but, where it is so large, it retards early development. The water influence is striking, as the fruits (peaches, for example) ripen from six to ten days later on the shore than two to four miles inland.



1726. Illustrating the bracing of the end post in a fence or trellis.

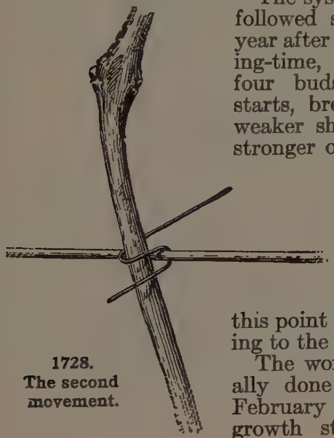
Stock and pruning.

One-year-old plants are the choice for planting. These should be well grown and healthy. Two-year-old plants are often only one-year culls. The plants are set as early in the spring as possible on land that has been previously prepared by growing a cultivated crop. Plants set in sod or on unprepared land do not thrive, and poor growth the first year is not made up two years later. The stock is heeled-in as soon as it comes from the nursery, but is left heeled-in only until the ground is ready for planting, which is as early as possible. When planting, time is saved by plowing a furrow, sometimes by throwing out two furrows, one each way. A man with a spade deepens this, or loosens the soil in the bottom, and then packs it again firmly around the roots. Before planting, all broken and damaged roots are cut away and sometimes the healthy ones are cut back. (Fig. 1724.) The tops are cut back to two to four buds. Distances of planting vary greatly, depending on the variety and the ideas of the planter. The popular distances are 7 by 10 feet to 8 by 10 feet for the small-growing varieties, to 9 by 11 feet for the larger-growing varieties. A few of the small-growing varieties are planted 6 by 9 feet, but this is exceptional. The first year the vines are allowed to run as they will. (Fig. 1725.) The posting is done the second or third year. This consists of driving posts sharpened at one end or digging holes and setting them about 21 to 27 feet apart. One post is set for each three vines. The end posts are either braced the same as ordinary fence-posts or anchored. (Fig. 1726.) Various anchors are used, such as large stones buried in the ground, cement used the same as stones, or a patent anchor which consists of a V-shaped piece of iron to which is attached a wire. This is driven in the ground to a depth of 30 to 36 inches. The posts are 8 feet in length, usually cedar or chestnut, and cost from 15 to 25 cents each—an average of 20 cents. The wiring is done the second or third year, preferably the second year, and consists of stretching two No. 9 galvanized wires the entire length of the row. The first is about 30 inches from the ground and the second about 30 inches above this. Some use three wires, but two are more popular. The wires slacken easily and the posts heave some every winter. This must be corrected regularly before tying the grapes. Drive the posts to place with a ten- or twelve-pound mallet and tighten the wire by turning the patent stretcher on the anchored posts. When putting the wire on the posts and tying the vines to the wire always place them on the windward side, as they are less likely to be blown down and damaged. The vines may be secured with raffia or with wire. (Figs. 1727–1730.)



1727. Tying with wire. The first movement.

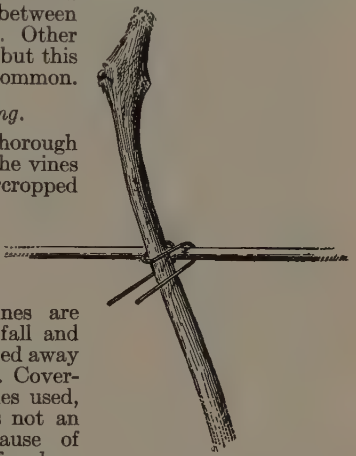
Pruning systems are many and varied, and the advocates of each system claim for their ideal special merits. Kniffin, Improved Kniffin, Fan, Arm and High Renewal systems are all used to some extent, but the Fan and Improved Kniffin are the most popular. Many growers believe that it is impossible to prune to a definite system, but by others this is not found to be the case. Many leave the necessary number of strong healthy canes and tie them up as best they can space them on the wires. From twenty-eight to forty buds is the popular number to leave, and the ideal of the grower is the only guide on which canes to leave these buds. The preference is usually given to the strong quality-looking canes on which the buds are close together.



1728. The second movement.

The system of pruning to be followed should be started one year after planting. As at planting-time, cut back to three or four buds and after growth starts, break or rub off the weaker shoots. This gives the stronger ones an opportunity to thrive. Tie to the lower wire. The second season it may be advisable to cut back similarly, especially if the growth has been weak. From this point train the vines according to the system to be followed.

The work of pruning is usually done in the spring, from February to April, before any growth starts. If growth has started, the vines will bleed. The brush is gathered, in most cases, with a pole about 11 or 12 feet long, 3½ inches in diameter at one end and tapering to about 1½ to 2 inches. This must be of strong material that will bend without breaking. A chain is attached from 24 inches to 36 inches from the large end, and as it is drawn by the team the brush collects between the chain and pole. Other methods are used, but this is by far the most common.

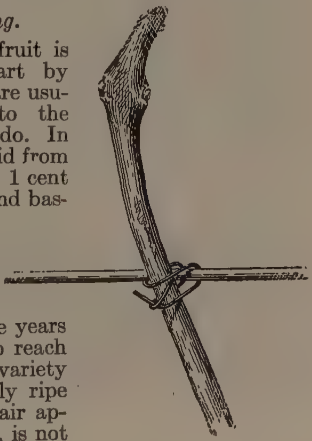


1729. The third movement.

Tillage and fertilizing.

Cultivation is thorough for best results. The vines are sometimes intercropped with cultivated crops the first year after planting, but later they require all the care. The vines are plowed up in the fall and disced and grape-hoed away the following spring. Cover-crops are sometimes used, but the practice is not an extensive one because of damp conditions for harvesting in the fall. Cover-crops are sometimes not plowed under till the following spring. The tying is done by women and girls in early spring before the buds are so swollen that they are easily damaged. Many materials are used, but the most common are wire and a soft wool twine made for the purpose. The twine is most used, although the wire is very handy. The canes are spaced when tying, and thus held in place until the tendrils of the new shoots secure them to the wire.

Fertilizing is still done in a haphazard way. Some of the best men make a regular practice of mulching the roots with farmyard manure in the fall. Some apply no farmyard manure at all. The use of commercial fertilizer is still in the experimental stage. Its value is admitted but its use is not fully understood. On light and gravel soils some potash compounds are being used. On the deep alluvial soils some growers are using it in the form of wood-ashes rather than the prepared commercial product. Some bone-meal, at the rate of 300 to 600 pounds to the acre, is being used also. Some state profitable results from their methods; others think that with light applications of farmyard manure and thorough cultivation the commercial fertilizers are not required.



1730. The tie complete.

Harvesting and marketing.

The cutting of the fruit is done for the most part by women and girls, who are usually paid according to the amount of work they do. In some cases they are paid from $1 to $1.25 a day, but 1 cent for an eight- to ten-pound basket is more satisfactory. Cutting starts as soon as the earliest grapes are ready for the market. In Canada, Champions have of late years been the first variety to reach the wholesaler. This variety colors before it is really ripe and, though having a fair appearance in the baskets, is not really ripe. Sharp criticism is leading the growers to be more cautious and to some extent drop the variety for the more satisfactory Campbell and Moore Early. These varieties are later, but please the purchaser. For wine purposes the fruit is left on the vines as long as possible so that it becomes fully matured. Grapes, unlike apples and especially pears, do not ripen off the vines and must be left until fully mature if the highest quality is expected, especially for dessert.

Of late years large acreages have been planted especially for the markets of the Canadian West. Coöperative associations have been organized to handle all varieties extending over the season; but, in the case of one large company, one variety only, Worden, is handled. This ripens before Concord and consequently brings a high price. The location of the vineyards of this particular company is ideal; the fruit is of good quality and ripens early and it seems that under those particular conditions the Worden is the most profitable grape to grow.

The forming of coöperative associations for the purpose of marketing the fruit has the distinct advantage of improved distribution. It has also cut down the handling expenses. Very few baskets, except special orders, are sent great distances by express. The coöperative associations have enabled the growers to secure car rates, and though prices have been comparatively low, even as low as 10 cents for an eight-pound basket, f.o.b. shipping station, the cheap and rapid methods of handling have made the industry profitable.

Returns.

Grapes, as grown at the present, might be considered a long-term investment with every prospect of regular dividends. The cost of planting, posting and early cultivation is comparatively high, but the vines bear early. Good crops are produced the third and fourth years after planting and the following year the vines should be in full bearing. The cost of planting and growing an acre of grapes to three years of age can only be estimated. Men, methods and conditions vary so much that no figures can be taken as absolute; but the figures and calculations serve as a guide and as such they are given here:

FIRST YEAR.

Land	$125 00
Fall preparation of land	3 00
Spring cultivating and marking furrows	1 50
Cost of 435 vines at 4 cents	17 40
Planting	3 00
Cultivating	3 00
Fall plowing	2 00
Total expenditure for first year	$154 90

SECOND YEAR.

Working soil in spring	$1 50
Cultivating	3 00
Pruning and tying	1 00
120 posts at 20 cents	24 00
120 posts (including digging and setting) at 5 cents a post	6 00
Staples, wire and wiring	22 00
Total	$57 50

THIRD YEAR.

Pruning	$1 50	
Tying	50	
Cultivating and plowing	5 50	
Fertilizing	8 00	
Spraying twice	1 00	
Average crop for third year 435 baskets an acre.		
435 baskets at 12 cents		$52 20
Cost of 435 baskets at $34 a thousand	14 79	
Picking 435 baskets at 1 cent a basket	4 35	
Covering	1 00	
Delivery	75	
Total expenditure for third year	$37 39	
Total revenue		$52 20
Net revenue		$14 81

Total expenditure for first three years:		
First year	$154 90	
Second year	57 50	
Third year	37 39	
	$249 79	
Third year revenue		$52 20
Net expenditure for three years	$197 59	

FOURTH YEAR.

Pruning	$3 00	
Tying	2 25	
Gathering and burning brush	50	
Spraying	1 40	
Plowing and cultivating	5 50	
Fertilizing	8 00	
800 baskets at 12 cents		$96 00
Cost of 800 baskets at $34 a thousand	27 20	
Picking 800 baskets at 1 cent a basket	8 00	
Covering	2 00	
Delivering	1 00	
	$58 85	$96 00
Profit		$37 15

The late J. W. Spencer, in his article in Cyclopedia of American Horticulture, on "Grapes in the North," gave the following as submitted by A. B. Clothier, Silver Creek, N. Y.:

Plowing and marking an acre of land	$3 00
Number of plants, 8 x 9 feet, 605 cost	12 10
Cost of planting	1 50
Number of cultivations first season, seven; cost	7 00
Cost of cultivation second season	7 00
Number of pounds of wire for two-wire trellis, 600 pounds; staples, 6 pounds; cost	22 80
Number posts for trellis, 202; number braces, 20; cost	14 14
Cost of putting up trellis	3 00
Cost of acre of grapes, exclusive of land	$70 54

Varieties.

The prospective planter will do well to consider carefully the best-known and most popular varieties before planting. More than 75 per cent of the grapes planted in the commercial sections of Canada are Concords and Wordens. The same is true of New York State. The Concord almost alone is used in the grape-juice industry. It is the leading fermented wine grape also. Worden is in second place, being a little earlier, and although a smaller yielder, is cutting into the Concord market for ordinary purposes. Lindley, Wilder, Vergennes, Agawam, Catawba and some related varieties all hold a place for general market purposes and the plantings are increasing. When quality is expected, these are the varieties to grow, but the yield will not be so heavy as for the Concord. Delaware is in good demand because of its quality when well grown. Moyer and Brighton are giving way to better varieties.

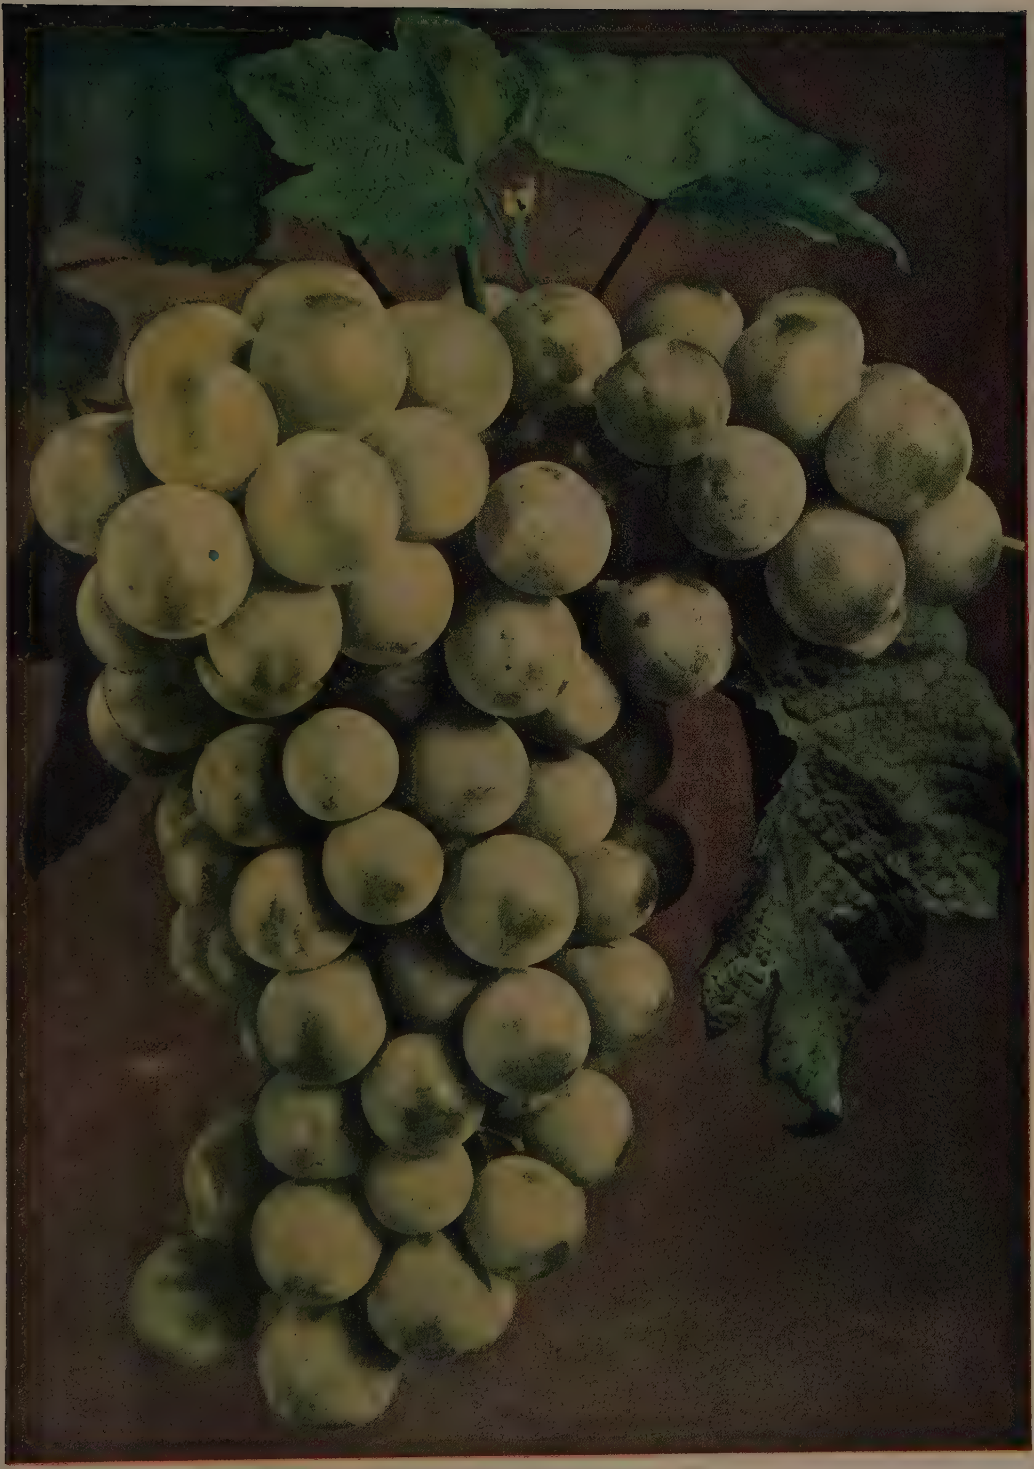
The Niagara, in spite of its many drawbacks, is still a favorite, and although a few years ago it suffered somewhat from over-advertising, it has again found its proper place and is in steady demand. The newer varieties have not been tested long commercially and it is well for the new grower to plant them only in limited numbers until they have proved they are worthy of a larger place.

All the commercial varieties grown out-of-doors are Labrusca or Labrusca-vinifera hybrids and seedlings, and no attempt is being made to grow the pure vinifera.

F. M. CLEMENT.

Grapes in the South.

The region south of the 38th degree north latitude has in it more native species of grapes than all the world besides. This alone would lead one to suppose the South naturally adapted to vineyard culture. Yet New York, Ohio and California up to the present far excel it in vineyard area, although only three or four species are native in these states. The cause of this is that diligent experimenters and originators have pro-



XLIX. The Niagara grape.

duced varieties of good marketable value adapted to those regions, from natives of the regions, or hybrids of natives with hardiest foreign kinds. In the case of California, the vinifera varieties are mostly grown because the climate and other conditions are so similar to those of the native region of the vinifera. But the South has chiefly planted the northern and foreign varieties which succeed but indifferently in most southern localities, and has neglected almost entirely its native varieties until quite recently. Now experimenters have shown that most excellent and very successful varieties of all colors and seasons can be and have been produced by selection and hybridization of some of the large fine-fruited varieties.

While the foregoing predicts by actual existence in practical market vineyards in a number of localities in the South what is in store for the South as a whole, the present state of grape-culture in that region at large is a different matter. Information gathered from best sources throughout the South shows that grape-culture is a very small industry.

Varieties.

The leading varieties cultivated in the northern sections of the South are Catawba, Concord, Delaware, Early Victor, Elvira, Ives, Moore Early, Moore Diamond, Niagara, Norton Virginia, Perkins, Worden, Wyoming. Favorable mention is made of America, Beacon, Brilliant, Campbell Early, Gold Coin, Green Mountain, Laussel, Ozark, Presly.

East of Texas and south of Tennessee, the following are chiefly planted: Brighton, Champion, Concord, Delaware, Diana, Diamond, Elvira, Goethe, Hartford, Herbemont, Ives, Missouri Reisling, Moore Early, Niagara, Norton Virginia (Cythiana), Perkins, Worden. Of the muscadine class for wine: Flowers, James, Mish, Scuppernong, Thomas. Favorable mention, of varieties testing, is made of Brilliant, Bertrand, Carman, Fern, Gold Coin, Jaeger (Fig. 1731), Laussel, Marguerite, Superb. In the southwestern section, west of the 96th meridian, are chiefly planted the Herbemont, Jacquez (Black Spanish, Lenoir), Niagara and Golden Chasselas, Malaga and some other vinifera varieties near the Gulf coast and in western Texas under irrigation. By several who have had them under trial for several years favorable mention is made of Bertrand, Brilliant, Carman, Fern, Jaeger, Marguerite, Muench, Neva, Perry, as furnishing successful table and wine grapes for this region.

1731. Jaeger.—Hybrid of Vitis Lincecumii and an æstivalis offshoot. (×½)

The following varieties are superior for commercial and home planting in the South, especially the Southwest, and some in the North: Headlight, Brilliant, President, Captivator, Hidalgo, Hernito, Delakins, Salamander, R. W. Munson, Mericadel, Ericson, Krause, Bailey, Extra, Blondin, Jaeger, Carman, Ellen Scott, Armalaga, Edna, Fern, Last Rose, named in order of ripening. These cover a season of ripening in north Texas (latitude of Atlanta, Georgia), from June 25 until September 15 or later. They include white, red and black colors in their different shades, many comparing favorably in appearance and quality with the better vinifera grapes, while the vines are all perfectly hardy in the South and some of them far north, making a fine record in New York and even about Boston. Some of these varieties are now planted largely along the Gulf coast country, where vine-culture was supposed to be impossible a few years ago.

The section of Texas south of San Antonio, lying between the Gulf and the Rio Grande River, as large in area as the state of New York, has a climate and soil excellently suited to the vinifera grapes, and in the last six years, since railroads began to ramify that section, and where irrigation facilities are afforded, considerable plantations of vinifera grapes have been made, the Flame Tokay, Malaga (Pensé), Muscat of Alexandria, Cornichon, Black Morocco, and so on, being the varieties chiefly used. Of course these require grafting upon resistant stocks, in all but the very sandy soils.

Georgia.

For Georgia, Hugh N. Starnes contributes the following notes:

"Leading varieties of grapes for Georgia are as follows: Ives, Concord, Niagara, Delaware, Moore Early, Goethe, Lindley; and for wine, Norton Virginia, Scuppernong and Thomas.

"The general distance apart to plant is 10 by 10 feet; Delawares 8 by 8 feet; Rotundifolias 30 feet. Single-stake spiral method of training is chiefly used, and either spur-renewal or cane-renewal pruning employed, according to circumstances. Some growers employ trellises instead of single stakes, using either one or two wires and adopting the umbrella Kniffin or low wire arm spur Kniffin system of training.

"Very little wine is now made in this state, and that is nearly all claret from Norton Virginia, Ives or Concord. In southern Georgia a poor article of Scuppernong wine is made, but it is not adapted to trained palates. Delaware and Goethe blended are sometimes used to make a very good Rhine wine, and when properly handled sometimes produce an excellent article. Goethe must, reinforced with 20 per cent of California brandy, makes a good pale sherry; yet it is difficult to sell wine here profitably. When it can be sold at all, prices range from 50 cents to $2 a gallon, according to the grade. Grape vinegar, while generally regarded as inferior to cider vinegar, will bring about 25 or 30 cents at retail and 20 cents wholesale, and at these figures is more profitable than wine.

"When sold fresh, the grapes are generally shipped in refrigerator cars in ten-pound baskets to different northern points. Later shipments take a southerly direction to Atlantic, and Gulf seaports. Sometimes the regulation six- or nine-carrier peach-crates are used for shipping grapes, but are not so satisfactory as the ten-pound separate baskets. Delawares are generally shipped in five-pound baskets. Returns are uncertain. They vary from 1½ cents a pound to 5 cents according to circumstances. Sometimes as high as 10 cents is realized on very early and very late shipments or with choice grapes, but this is seldom. Distilleries pay three-fourths of 1 cent a pound delivered, or gather and pay ½ cent a pound. If only one ton to the acre of grapes is the yield, the gross return (and also the net return) an acre would thus be from $10 to $15. This is more than cotton ordinarily nets. With two tons to the acre of grapes, which is not an enormous yield, the return would be $30 an acre delivered at the still. To those who have no scruples in regard to so disposing of their crop, this is probably the most profitable method. There are local stills in almost every county.

There is not much encouragement now for grape-raising in Georgia, and vineyards are annually being destroyed by hundreds of acres. Some planting, however, is still going on in southern Georgia, in the "wire grass" country, where the industry is still found profitable by reason of the fact that the northern market may be entered ahead of competition, and also that insects and fungous pests have not yet put in an appearance in that region.

Planting, training, and the like.

The vines of the true southern grapes, such as Herbemont and the Post-oak grape hybrids, are planted 12 to 14 feet apart, in rows 9 feet apart, while such northern varieties as are planted are set 8 feet apart in row. The Muscadines, such as Scuppernong, are mostly grown upon arbors about 7 feet high and rarely or never pruned, although trained on trellis, as are other grapes, and, pruned early in fall, after leaf-fall, succeed excellently. The culture is mostly with the plow, turning first away and then to the rows, hoeing the space along the row not reached by the plow. The trellis mostly used is the 3-wire trellis; first wire at 18 to 24 inches from the ground, and the others successively 1 foot apart, above the first. The training is commonly an indifferent attempt at the Kniffin system, and no system is generally carried out. Some pinch back the leading shoots once, few twice. Some use single posts and spur-prune. A few have made the Munson canopy trough trellis of 3 wires, and report most favorably of it.

Fungicides are used successfully by some. Others plant only such as Ives, Norton Virginia, Moore Early, Perkins, and some other varieties not subject to rot and mildew, so as to avoid spraying. They also avoid, thereby, having grapes of the finer qualities, and get only the lowest prices. From such mostly come the report that grape-culture with them is unprofitable. So it should be, as such grapes in the market have the effect to depress prices on all kinds of grapes. In the moister parts of the South, black-rot, downy mildew and ripe grape-rot are very prevalent, but, excepting the ripe rot, are readily overcome by the bordeaux mixture spray properly applied.

Few growers in the South use fertilizers in their vineyards. Some use barnyard manure, but the more intelligent use cotton seed or cotton-seed meal in connection with ground bone, kainit and soluble phosphates.

Marketing and profits.

The crop is mostly marketed fresh in the local or nearby markets, as the ordinary freight and express rates will not permit profitable returns on the varieties mostly grown. But it has been demonstrated that fine grapes that will carry well can easily be grown in the South, and, when handled in best manner in neat baskets, are profitable.

There are a few established wineries in the South, which use Ives, Norton Virginia, Herbemont, LeNoir, and the Scuppernong and other Muscadine varieties. The chief complaint of wine-growers is that legislation brought about by the prohibition movement is adverse and often entirely prohibitive. In consequence, some have bottled the juice fresh under some sterilizing process, but the people are not yet educated up to the use of this excellent, healthful, nourishing beverage; yet the demand for it is growing, and may be largely increased by enterprising makers.

Reports collected from all parts of the South state the profits all the way from nothing up to $150 an acre, sometimes higher, and it is clearly evident that the intelligence and enterprise of the planter are the chief elements in controlling profits. Of course, localities, soils and varieties play important parts, but an intelligent grower would not select poor locality, situation, soil and varieties to start with, just as he would not pursue poor methods in the conduct of the business.

There appears no reason why the South may not become one of the greatest grape countries in the world and it promises everything to the wide-awake, intelligent grape-grower, for its capabilities are unlimited in the production in quality and season when no other section competes with it, and it has vast markets at home and in the great cities just north of it.

T. V. Munson.

Grapes on the Pacific slope.

Grape-growing was introduced into California by the Franciscan Missions during the latter half of the eighteenth century. At all the missions from San Diego to Sonoma the same variety was cultivated practically exclusively. This variety, now known generally as the "Mission" or locally as the "California" and "El Paso," reached California from Mexico through the Jesuit missions of lower California. It seems probable that it was brought over from Europe as early as the time of Cortez but it has never been completely identified with any European variety. It is very close to the Monica of Sardinia which it resembles in its great vigor, heavy growth, the form of its leaves, the size, shape, color, texture, and flavor of its fruit, and differs principally in the less dense indument of its foliage. It seems probable that it is a seedling of this variety selected by the padres on account of its close resemblance to its parent, which is a favorite with the monks of Sardinia. It was admirably adapted for the purposes of the missions, for besides being a good table grape, keeping well and not sensitive to primitive methods of handling, it could be used for the manufacture of white or red wine and was especially adapted to the production of a sweet wine of sherry type.

For a long time, even after the American occupation of California, it remained the only variety grown in vineyards, but, with the arrival of immigrants from various grape-growing countries, other varieties were introduced, and, at present, it is little grown in California except as a good, cheap, easily handled table grape for local supply and in some regions as an ingredient in the manufacture of sweet red and white wines. It still forms the bulk of the vines grown on the Mexican plateau and extends into New Mexico and southwestern Texas, but is gradually giving way even there to varieties better adapted to special purposes. At present, Zinfandel for wine, Muscat of Alexandria for raisins, and Flame Tokay for shipping, constitute the bulk of the grapes grown in California, although about twenty-five varieties are grown on a large scale and over twice that number in considerable commercial quantities. Including all the varieties which occasionally or locally appear on the market as table, raisin or wine grapes, there are over one hundred varieties of commercial importance.

All these varieties, with one or two unimportant exceptions, belong to the European type, *Vitis vinifera*. Varieties of *V. Labrusca* and other American types grow vigorously and bear well except in the hottest and driest sections, but the grapes are unsuited for the main purposes of the industry in California. They cannot be made into raisins, are inferior to vinifera for wine and are less suitable for distant shipment as table grapes. Scattering, small patches of the variety Pierce (an improved sport of Isabella) are grown in the cooler parts of the northern coast counties, and an occasional patch of Concord in the San Gabriel Valley. The crop of these vines finds a market in San Francisco, Los Angeles and other large coast towns and is often very profitable, but the market is small and easily over-stocked. These grapes attain regularly a higher percentage of sugar and lower acidity than is usual in the eastern states and they have been used successfully in the manufacture of unfermented grape juice, for which they are particularly adapted.

The vineyard industries of the Pacific slope, however, will always be based principally on the growing of vinifera grapes, owing both to their greater intrinsic value for most purposes and to the fact that they cannot be grown on a large industrial scale in any other part of the United States.

Certain American species of vines are nevertheless essential to the success of California grape-growing, owing to their resistance to the phylloxera which rapidly destroys all vinifera varieties whenever it secures a foothold in the vineyard. They are useful as stock on which to graft the vinifera varieties and are extensively used in the northern and central coast counties and in certain sections of the great valley and the Sierra foothills. The insect has not yet become established in southern California nor in Imperial. The chief resistant stocks used are varieties of riparia and rupestris, although certain hybrids of these species with Berlandieri, and vinifera are also used for special conditions. The Labrusca varieties are almost as susceptible to injury from phylloxera in California as the vinifera and also require grafting on resistant stock in infested regions.

The most essential requirement for the successful growth and bearing of vinifera varieties is a dry summer with abundant sunshine and a winter cold enough to render the vines dormant for at least several weeks. These conditions are found in California from the Mexican to the Oregon borders, and in favored locations in several of the other Pacific slope states. Along the coast north of Monterey Bay, the summer sea fogs interfere with the ripening of the grapes and make the control of the oidium difficult. These sea fogs cover a belt which in the north extends considerably into the interior but gradually becomes narrower as one proceeds south, until in the latitude of Santa Cruz, where the mean annual precipitation falls below 20 inches, grapes can be grown almost down to the sea. In the remainder of California, grapes can be grown almost everywhere that the elevation above sea-level is not too great. In the latitude of Napa the limit is about 1,500 to 1,800 feet. Farther south, vineyards are found at Ben Lomond in Santa Cruz County at 2,500 feet and at Colfax in Placer County at 2,400 feet. At these elevations vines succeed only in favored locations. In others and at higher elevations, killing frosts often occur both in spring and autumn.

Grape-growing in a large way began in California soon after the American occupation. In 1858, according to the State Register, there were 3,954,548 vines in the state, equivalent to about 6,500 arces. Collections of European varieties were introduced and state aid was secured for the promotion of viticulture. By 1870, the vineyard acreage had increased to nearly 30,000 acres. Wine was produced in fairly large quantities, but its sale was at first attended by many disappointments which discouraged planting and for ten years the new vineyards barely sufficed to compensate for the loss of vineyards by phylloxera in the north and a peculiar disease of unknown cause in the south.

In the meanwhile, the demand for Californian wines increased and a propaganda for extension with more suitable methods and better varieties was earnestly taken up. Again the state granted funds liberally, and the agitation resulted in vine-planting and cellar-construction throughout the state. At the same time, vast plantings were made in the new Fresno region and between 1880 and 1883 the vineyard area of California increased from about 35,000 acres to nearly 140,000.

This rapid expansion naturally led to over-supply and inferior products, which restricted further extension. In the period from 1891 to 1897 the vineyard area actually decreased owing to the rapid destruction of the vines of the large Santa Clara section by phylloxera and drought. In 1904 the vineyard area was estimated to be about 200,000 acres and since then the new plantings, especially of table grapes, have been steady and the area in 1913 may be estimated roughly at about 385,000 acres, of which about 75,000 consists of table grapes, 130,000 of raisin grapes, and 180,000 of wine grapes.

The vineyard products of California, according to the statistician of the California State Board of Agriculture, for 1912 were: Wine, 47,491,772 gallons; brandy, 8,721,693 gallons; raisins, 185,000,000 pounds; table grapes, 6,363 (1913) carloads.

1732. Trunk of a vinifera grape, with the fruit-bearing canes cut back.

Vinifera varieties of grapes have a very wide range of adaptation. They grow in all fertile soils, but succeed best in light, deep, warm loams in the valleys and on the hillsides. The American varieties used as stocks are less adaptable and some care must be exercised in choosing a stock suited to the chemical and physical character of the soil. The extremes of temperature and elevation endured by vinifera vines are very great, especially if care is taken in the selection of varieties.

In the Pacific coast states outside of California, the growing of grapes is still largely experimental. In parts of Oregon and near the confines of Idaho and Washington almost to the borders of British Columbia, vinifera varieties of table grapes are giving very promising results in favored locations. The vines need some protection in the winter by covering with straw or earth, but the hot, dry summer will ripen even such southern and late varieties as Flame Tokay and Cornichon. The American varieties succeed in a much wider territory in these states. The varieties most favorably mentioned are Concord, Delaware, Diamond, Moore, Niagara and Worden. In parts of Arizona and of southern Nevada and Utah, vinifera vines have been planted and promise to be profitable for local sale or, in special locations, for early shipments.

Propagation and cultivation.

New vines are grown from cuttings of one-year-old dormant wood. These cuttings should be from 10 to 18 inches long, the shorter cuttings for moist soils in the cooler localities and the longer for drier soils in hot regions. A 14-inch cutting is usually employed. It is generally best to root the cuttings in a nursery and plant them out in the vineyard the following spring. In well-prepared, moist soil they may be planted directly in place, only one bud being left above the surface. Where phylloxera exists, resistant vines must be used. These are obtained by grafting a one- or two-bud cutting of vinifera on a 9- to 12-inch resistant cutting from which the buds have been removed. This graft is united in a callusing bed, rooted in the nursery and planted out in place when one year old. The resistant stock is often first rooted in the vineyard and grafted in place when one or two years old. This method is uncertain and gives many poor unions except with a few stocks and in very expert hands.

1733. The canes of a vinifera grape before pruning.

The soil should be plowed as deeply as practicable before planting. The best vineyardists turn the soil 9 to 12 inches, often following with a subsoiler penetrating 6 or 8 inches deeper. This treatment results in a more complete "stand," quicker development and full bearing at three to five years. It is especially useful for grafted vines.

Resistant stocks.

The principal phylloxera-resistant stock grown is the rupestris St. George (=du Lot). It succeeds in a wide variety of soils providing they are deep, permeable and well supplied with water below. In shallow, compact or very wet soils it often fails. It forms good unions with most of the common vinifera varieties. Exceptions seem to be, in some localities, Emperor, Cornichon and Muscat. For the shallower soils of the coast counties, riparia × rupestris 3309 is to be recommended; for stiff clay soils, Berlandieri × rupestris 420 A; for rich, moist, well-drained soils in the cooler locations, riparia gloire de Montpellier. For varieties of difficult affinity the Mourvèdre × rupestris 1202 is promising in soils similar to those suited to St. George.

Pruning and thinning.

It must be recognized that the vinifera grapes have a different habit of growth from the native grapes grown in the East. They are not always trained on wire trellises. The old trunk (Fig. 1732) is short and stump-like and supports itself. The cane-growth (Fig. 1733) is relatively short, and it is cut back to near the head of the trunk, as shown in Fig. 1732, and also in Fig. 1734.

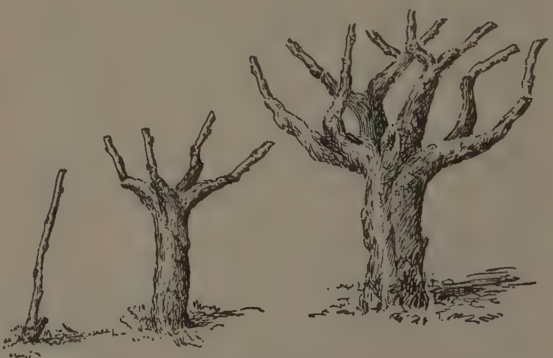
In the first year, the vines need no attention except thorough cultivation and one or two irrigations in dry sections. In the following winter, the dormant growth is thinned to one cane which is cut back to one or at most two buds. The vines should then be staked. Redwood stakes, 3 to 4 feet long and 1½ inches thick, are the best, placed 2 inches from the vine on the leeward side. These are sufficient for the goblet system of training, but longer stakes may be necessary when canes are left at pruning.

During the second year, all buds or shoots but one should be removed before they have made any considerable growth. The whole energy of the vine is thus forced into a single shoot which should be carefully tied to the stake and, if vigorous, topped at about 3 feet to cause it to produce laterals. All suckers from below ground should be carefully removed at their origin and also any cion roots which may develop on grafts. At the second winter pruning, all canes but one should be cut off clean if more than one has been allowed to grow. This cane should then be cut back to the height at which it is desired to "head" the vine, which will be about 15 inches for small-growing vines such as Zinfandel and 24 to 30 inches for heavy-growing vines such as Flame Tokay. Table grapes, as a rule, are headed higher than wine or raisin grapes. When strong laterals have developed, these should be left with one or two buds when they occur in positions where it is desired to develop arms.

In the third year, no shoots should be allowed to develop on the trunk of the vine within 8 to 15 inches of the soil, according to the height of the head. It is usually necessary to pinch back all the shoots from the head when they are 15 to 18 inches long to protect them from wind injury while they are still brittle. At the end of this year, the vine should have developed sufficiently so that it can be given three to six spurs in the positions desired for the permanent arms. These spurs should consist of two to four buds, the more vigorous the vine the more spurs and the more buds.

In the future prunings, the number of spurs is gradually increased until the vine reaches its adult stature. The number will vary from four or five to fifteen or twenty, according to the vigor of the variety and the distance apart of the vines. During the first four or five years, great attention should be given to forming the vine with a clean vertical trunk and symmetrically placed arms and also, with grafted vines, to the careful removal of stock suckers and cion roots. As the vines become older and less vigorous, the spurs left at the annual winter pruning should be shorter, consisting usually of only one or two complete joints.

This method of pruning, illustrated by Fig. 1734, is known as the vase or goblet method and is adopted in most of the vineyards of California. A few varieties, notably the Sultanina (=Thompson Seedless) do not bear satisfactory crops with this method. For such varieties the treatment for the first three or four years is the same, but at that time it is necessary to erect a trellis. This consists usually of two No. 11 or No. 12 galvanized iron wires stretched along the rows at about 18 and 36 inches from the surface of the soil. These wires are supported by redwood stakes 6 feet long and about 2 inches in diameter. The vines are then pruned by leaving a suitable number of "fruiting canes" about 4 to 6 feet long, which are tied to the wires. Near and below the base of each fruiting cane is left a "renewal spur" consisting of two buds, whose function is to supply a fruit-cane and renewal spur for the following year. Care should be exercised to choose fruit-canes which originate from the spurs of the previous year and not from older wood. The vines, instead of being given the symmetrical goblet form described, should



7734. The common short-pruning goblet system used for the vinifera grape in California.

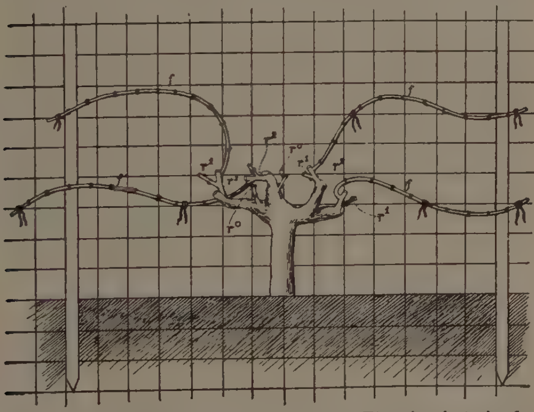
be flattened fan-shape to facilitate cultivation, which can take place only in one direction. This method of pruning and training is shown in Fig. 1735.

Goblet-pruned vines are planted on the square system from 7 to 12 feet apart, 8 feet apart being usual for the northern coast counties and 9 or 10 feet for the hotter regions. Muscat of Alexandria vines are usually planted 6 by 12 feet to 8 by 14 feet to facilitate drying the raisins, and trellised vines are usually planted in the same way.

Some special practices and modifications of the usual methods are found to be useful in the production of table grapes for shipping. In general, the vines should be raised a little higher and the arms given a somewhat wider spread. This is to keep the fruit from contact with the soil and to spread out the bunches so that they will develop, ripen and color evenly. The removal of water-sprouts and sterile shoots, not needed for new arms, before or soon after the grapes set is also very useful. This tends to make the bunches and berries larger by concentrating the energies of the vine on the bearing shoots. An equally important effect of this practice is to facilitate the gathering of perfect bunches. When neglected, the water-sprouts often grow through the bunches. Such bunches cannot be gathered without injury. Some of the grapes are pulled off, some broken and, worst of all, some of them are slightly loosened around the pedicel. Most of the broken berries can be removed by the trimmers in the packing-house, but many of those simply loosened escape their scrutiny and are a fruitful cause of decay.

Many otherwise suitable grapes do not ship well on account of the excessive compactness of the bunch. A compact bunch is difficult to pack without injury and cannot be freed from imperfect berries without spoiling good berries.

This excessive compactness can be prevented by thinning before the berries are one-third grown. Thinning, moreover, increases the size of the berries, hastens ripening, promotes coloring, and lessens some forms of sunburn. The practice has been employed with success by growers of Tokay, Black Morocco, and other grapes in northern California. While apparently costly, the expense is often more than counterbalanced by the saving in trimming of the ripe grapes. The increase of quality thus becomes a net gain.



1735. The long-pruning of vinifera vines. The vine is trained on two horizontal wires.

f f, Fruit-canes growing out of the renewal spurs r^2 the previous year; r^1, renewal spurs to supply fruit-canes for the following year; r^0, replacing spurs to supply wood for use when the over-elongated arms are cut back.

The bunches are thinned at any time after the berries have set and before they have reached one-third their mature size. No bunches are removed, but only a certain proportion of the berries of each bunch. The number of berries to be removed will depend upon how compact the unthinned bunches usually become. In general, it will vary from one-third to one-half of the total number. The thinning is effected by cutting out several of the side branchlets of the bunch. The branchlets should be removed principally from the part of the bunch which has most tendency to compactness, usually the upper part. The work can be done very rapidly as no great care is necessary in preserving the shape of the bunch. However irregular or one-sided the bunch looks immediately after thinning, it will round out and become regular before ripening. A long, narrow-bladed knife or a pair of grape-trimming scissors can be used conveniently for this work.

1736. Tokay grapes.

Harvesting and packing.

The grapes should not be harvested until they contain at least 17 to 19 per cent of sugar, varying with the variety and the locality. Unripe grapes are distasteful to the consumer, spoil the market for later and better grapes, and are more liable to deterioration from wilting and decay. After every care has been taken to produce good shipping grapes on the vines, their proper handling is no less important. A bunch of grapes which is perfect in the vineyard may easily be ruined by careless gathering or hauling before it reaches the packing-shed.

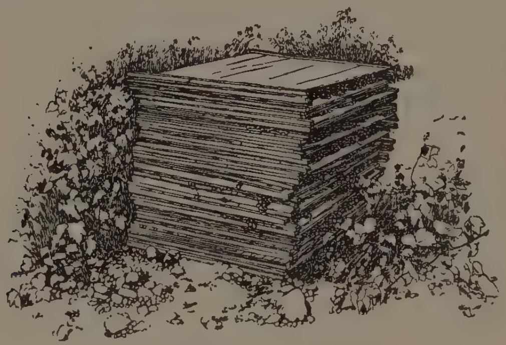
The grapes, in gathering and packing, should be touched as little as possible and handled only by the main stem. They should be placed carefully in wide, shallow boxes in a single layer. Hauling to the packing-house should be done very carefully, in wagons provided with springs. The grapes should be protected from the dust and the direct rays of the sun, and the boxes should be so stacked that there is no danger of crushing the grapes. Fig. 1736 shows two crates or boxes of grapes.

The most usual way of packing table grapes in California is in square chip baskets holding about five pounds and placed in fours in open-sided crates. Extra-large bunches or "clusters" are sometimes packed in oblong baskets of twice this size, of which two are placed in a crate. Experiments have been made with various "fillers" to protect the grapes during transit and to increase the time during which they will remain in good condition. The cork-dust or waste used in Spain for the grapes of Almeria is unavailable. Various substitutes have been tried. Early attempts to utilize ordinary sawdust for this purpose proved unsuccessful for the reason that the grapes failed to hold in good condition and absorbed disagreeable flavors from the wood. Recently it has been demonstrated that pure, dry redwood sawdust, from which the chips and finest particles have been removed by screening, is even superior to ground cork for grape-packing. Redwood is neutral in odor and flavor and imparts no disagreeable taste to the grapes packed in it and held in cold storage. During the past three years this method of packing and storing has received wide commercial application. The shipments of Emperor grapes packed in sawdust during 1913 amounted to nearly 300 carloads. Table grapes for local markets are often shipped in the fifty-pound "lug" boxes in which they are gathered.

Raisins.

Practically all the raisins in California are sun-dried. Artificial driers were formerly used to some extent to dry the second crop of Muscat and are still used occasionally to finish drying in seasons of early rains. The second crop is now utilized by the wineries.

Muscat grapes should not be gathered for raisin-making until they show at least 24° Bal.* of sugar. Better raisins are made at 26° to 27° Bal. The crop increases with increasing ripeness. At 27° Bal. the yield of raisins to the acre may be 40 per cent greater than at 23° Bal. The grapes are gathered on wooden trays with cleats, holding twenty-two pounds of grapes which dry to five and one-half to seven pounds of raisins. The trays are furnished with bottom and top end cleats which allow a space of 2½ to 3 inches for the grapes when they are stacked. The filled trays are placed in alternate rows running east and west where the soil has been given a slight inclination by means of a V-shaped scraper in order to expose the grapes more directly to the rays of the sun. After about nine to twelve days, the grapes are turned by placing an empty tray on top and inverting the two trays together. In about three to four days after turning, they are dry in good weather, but the total time of drying may vary from about ten days to nearly a month according to the ripeness of the grapes and the temperature and moisture of the air. The best raisins are made when the average maximum daily temperature lies between 85° and 90° F. Above 100° F. the grapes are somewhat injured in flavor and appearance but still make good loose or seeded raisins. If rain falls after the grapes have begun to dry, especially after they have been turned, they are liable to injury. When rain threatens, it is sometimes necessary to pile the trays up in stacks and to spread them out again as soon as the rain or the danger is over. In some seasons this stacking has to be repeated two or even three times, much increasing the cost and time of drying. (Fig. 1737.)



1737. Stacked trays of raisins.

When the grapes are nearly dry, the full trays are stacked in piles of 12 or more and covered with an empty tray. Here the drying is completed and the moisture equalized. They remain in the stack for a week or more and are then placed in large "sweat-boxes" holding about ninety pounds of layers, or 125 pounds or more of loose raisins. When fine layer raisins are made, these are picked out by hand before putting in the sweat-boxes and the layers separated by sheets of paper. The raisins are delivered to the packing-houses in the sweat-box.

Sultanina and Sultana grapes are sometimes cured in the same way as the Muscats, but the resulting raisins are of a dark amber-color and cannot compete with the light golden yellow Sultana raisins. These are made by passing the grapes through a "dip" and then through a sulfur-box before drying.

Various dips are in use, the commonest being composed of one pound of good potash lye in twelve gallons of water. This is kept boiling hot and after immersion in it for an instant, the grapes are plunged in cold water and placed on the trays. Some growers add an emulsion made of three-fourths of a pound of lye, one quart of olive or of the purest cottonseed-oil, and three quarts of water. A gallon of this emulsion is added to each ten gallons of the lye-dip. Some growers say that they secure equally good results by dipping simply in boiling water. Similar dips are sometimes used to facilitate the drying of second-crop or inferior Muscats and such grapes as Malaga and Feher Szagos.

After dipping, the grapes on trays are exposed to sulfur fumes and spread out to dry. In hot weather much of the drying is done in the stack, too much exposure to the hot sun tending to darken the color of the raisins.

Raisins or dried grapes are of four main classes: (1) Raisins proper, of which the dried fruit of the Muscat of Alexandria is the type. California produces more than half the world's crop of this class. Most of them are made from the Muscat of Alexandria or from its variation, the Muscat Gordo Blanco. When the demand is good, Malaga, Feher Szagos and occasionally other large sweet white varieties are used. (2) Sultana raisins are made from the Sultanina (=Thompson Seedless or Oval Kechmish). California also produces large quantities of this class, the principal centers of production being the upper San Joaquin Valley and Sutter County in the Sacramento Valley. The Sultana (=Round Kechmish), also a seedless grape, is grown in large quantities, principally in the Sacramento Valley. From it is produced a raisin resembling a small Sultana in appearance but more allied to a "currant" in flavor. Both of these varieties require long pruning with fruit-canes of 4 to 8 feet. (3) Currants which are made from the very small seedless Black Corinth and to a less extent from the somewhat larger White Corinth, are not produced on a commercial scale in California. The Black Corinth does not bear and the White Corinth produces a raisin which is too large to pass as a "currant" and too small to secure a remunerative price as a "Sultana." (4) Dried grapes are made from almost any kinds and are occasionally produced in large quantities when the price of fresh grapes is low. They are used for various purposes, principally for the manufacture of imitation wines in foreign countries.

Grapes for shipping.

Table grapes are grown all over California for family and local consumption and include hundreds of varieties, principally vinifera. The commercial growing of table grapes, however, is for the purpose of shipping to large centers of population, especially in the eastern states. It is localized in certain regions and utilizes a comparatively small number of varieties.

The earliest grapes come from Imperial County in June, followed in July and early August from Fresno, Kern and Tulare Counties and from the warm eastern slopes of the inner coast range in Yolo County. The earliest variety is the Luglienga, usually shipped under the erroneous name of Madeleine; the next the Chasselas doré, usually called Sweetwater; both are white. These varieties have not given satisfaction in Imperial, where Persian No. 23, and allied varieties, promise

---

24° Bal. means that the juice has the same concentration as a pure sugar solution of 24 per cent. The juice is tested by a Balling hydrometer for sale by all chemical supply houses.

better results for the earliest markets. The Khalili is even earlier then the Luglienga and seems promising for Imperial. Blue Portuguese is the only very early black grape that appears on the market and is of poor quality. Bellino is promising for Imperial County but loses its extreme earliness farther north. By the middle or end of July all varieties are ripe somewhere, the latest varieties ripening about that time in the earliest localities. Distinctions regarding earliness apply, therefore, more to districts than to varieties.

The Flame Tokay, which appears to be identical with the Amar bou Amar of Algeria, is the chief shipping grape of California. It fails to develop its bright red color in Imperial so that the first shipments are from the Winters and Vacaville region. The bulk of the crop is raised in the middle part of the Great Valley from Stockton to Sacramento, Lodi being the principal center. There are numerous other smaller centers of production, the latest being the Santa Cruz Mountains. The next most abundant varieties are the Malaga, the principal variety of the Imperial Valley, a white grape raised largely also in the San Joaquin Valley from Tulare to Stanislaus County, and the Emperor, a large, late red grape raised chiefly in Tulare and Fresno but more or less in several other counties from Los Angeles to Sacramento County. In the cooler regions its color is almost black. The Cornichon (=Malakoff Isjum), a long, late, black grape, the Black Prince (=Rose of Peru), a moderately early round grape, and the Verdal, a very late white grape, are also largely raised, the last only in the Santa Cruz Mountains. The Black Morocco (=Trevoti), the Ferrara, the Gros Colman and the Pizzutello are also raised in considerable quantities. Promising new varieties are the Olivette de Cadenet, Flame Muscat and some of the Persian varieties, especially the Paykani Razuki, a brilliant red grape which bears well only when grafted, except in the Imperial Valley. The Muscat of Alexandria and the Sultanina (=Thompson Seedless), while primarily raisin grapes, are shipped as table grapes in large quantities in most seasons. The only eastern variety grown for the market is the Pierce, which satisfies the small demand for a "slip-skin."

All the varieties of table grapes mentioned succeed with the goblet form of pruning, although some, such as the Malaga, Cornichon and Emperor, require fairly long spurs and in very rich soils even moderate long pruning.

The grape season in California extends over at least six months. The earliest varieties ripen in the Imperial and Coachella Valleys by or before June 1 and the latest varieties in the latest localities do not ripen until November 1 and in dry autumns may hang on the vines in good condition for a month longer.

Grapes for wine.

The great bulk of all the red wine, both dry and sweet, is made from the Zinfandel. This variety was introduced very early into California but its identity has never been established. It has many good qualities. It bears at an early age and with short pruning. If the first crop is destroyed by spring frosts it produces regularly a fair second crop. It succeeds best in the warmer parts of Napa and Sonoma Counties. In the cooler parts it fails to develop its color or flavor. In the hot interior it is subject to sunburn and its peculiar flavor becomes unpleasantly intense. Other widely grown red wine grapes are Petite Sirah, Alicante Bouschet, Carignane, Mataro and, in southern California, Blue Elbling. Varieties recommended for dry red wine in the coast counties are Petite Sirah, Barbera, Beclan and Cabernet Sauvignon; for the hotter interior, Valdepeñas, Lagrain and St. Macaire; and for sweet reds of Port type, Grenache, Alicante Bouschet, Tinta Madeira and Trousseau.

The dry white wines are made from a large number of grapes of which the chief heavy-bearing varieties are Burger, Palomino, Feher Szagos and Green Hungarian and the chief high quality varieties, Colombar, Semillon and the Rieslings,—Johannisberg, Franken and Gray. The sweet white wines are made from the above-mentioned heavy-bearing varieties and also from Mission, Grenache and other light-colored red grapes. Large quantities of wine and brandy are also made from the culls of raisin and table grapes and in years of over-production from the main crop. Varieties recommended for dry white wine are the Rieslings in the coolest localities, Semillon and Colombar for the warmer parts of the coast counties, and Burger, Green Hungarian and Vernaccia Sarda for blending wines in the interior. For sweet wines Palomino, Beba, Mission and Grenache are suitable.

Various degrees of pruning are needed for these different varieties but in a general way the heavy bearers should be pruned short and the fine varieties long.

Diseases and insects.

Vines on the Pacific slope are remarkably free from serious fungous diseases owing to the absence of summer rains. Oidium (*Uncinula spiralis*), the only exception, occurs everywhere but is controlled cheaply by one or two thorough dustings with fine sulfur in the warm interior and two to four in the coast regions. The ubiquitous saprophytic blue, gray and black molds sometimes injure late grapes in wet autumns.

Insect pests are more serious. The phylloxera renders resistant stock necessary in most of the older districts. The vine-hopper (*Typhlocyba comes*) is often very troublesome in the warmer regions, but its attacks can be much lessened by complete clearing out of green growth a week or two before the starting of the buds, timely use of a hopper-cage to trap the over-wintering adults in early spring before they deposit their eggs and by a nicotine spray in May or June when the first brood appears. Much injury is done locally by the grape root-worm, the larva of the grape beetle, *Adoxus vitis*. It can be controlled by spraying the vines in May with lead arsenate which kills the adults before their eggs are laid. Erinose (*Phytoptus vitis*) is widely distributed but seldom harmful and easily controlled with dry sulfur as used for oidium. Climbing cut-worms (larvæ of Noctuid moths) are very generally harmful to the buds and young shoots in many seasons. Most species can be controlled by the use of poisoned bait. The bait most used is made by mixing forty pounds of bran with two gallons of molasses and five pounds of arsenic. A better bait is made by mixing twenty-five pounds of bran and twenty-five pounds of middlings with five pounds of arsenic and applying dry. A pinch of the bait is placed at the base of each vine or, with large vines, in the center of the head. Grasshoppers and other general feeders are sometimes troublesome, especially in new districts.

A number of imperfectly understood diseases whose causes are unknown are recognized. The chief of these is the Anaheim or Californian disease. This name is inappropriate as it seems to occur also in southern Europe and Algeria where it is ascribed to over-bearing coincident with a series of dry seasons or other weakening causes. Another widely spread disease of a similar nature but less fatal is known as Little-leaf. Various causes for this disease have been suggested, but the most plausible opinion seems to be that it is a case of mal-nutrition due to unfavorable soil temperatures during the spring.

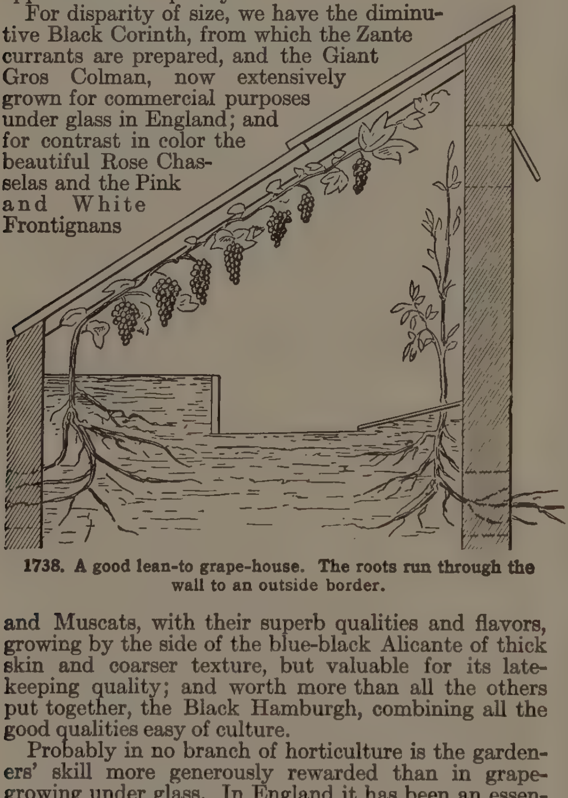
Grapes under glass. (See, also, page 1261.)

Under glass, the European varieties alone are used. This species, *Vitis vinifera*, is the vine of the ancients, and is indigenous to the more salubrious parts of eastern Asia and southern Europe. It is referred to in the earliest mythological writings of ancient Egypt and thence on numberless occasions, notably in the Bible and the New Testament. The story of the spies from the promised land, with its generous illustration, has excited the admiration and perhaps questioned the credulity of many of us. It is only fair, however, to state that the size of the cluster there represented has been amply borne out in recent years. The type *Vitis vinifera*, if there ever was a type, has become so merged and modified by cultivation in different climates and countries that it is difficult to trace it at the present day. Over 2,000 varieties are described, covering the widest range in size, color, texture and flavor, general appearance and quality.

For disparity of size, we have the diminutive Black Corinth, from which the Zante currants are prepared, and the Giant Gros Colman, now extensively grown for commercial purposes under glass in England; and for contrast in color the beautiful Rose Chasselas and the Pink and White Frontignans and Muscats, with their superb qualities and flavors, growing by the side of the blue-black Alicante of thick skin and coarser texture, but valuable for its late-keeping quality; and worth more than all the others put together, the Black Hamburgh, combining all the good qualities easy of culture.



1738. A good lean-to grape-house. The roots run through the wall to an outside border.

Probably in no branch of horticulture is the gardeners' skill more generously rewarded than in grape-growing under glass. In England it has been an essential feature of horticultural work for more than a century, resulting in fruit of a finer quality and flavor than that grown in the open air and very often enormous clusters, weighing from twenty to thirty pounds. Started there as a matter of luxury, it has become of late years a matter of profit, and vineries of large extent have been erected for commercial purposes. Probably this work has been retarded here by the introduction of the many very excellent varieties of our native grapes, *V. Labrusca*, so easily grown in the open air and so constantly improved by hybridizing with the European, and undoubtedly this work will yet result in a much closer approach to the standard of European quality.

The essential difference between American and European kinds is that in the American the pulp separates from the skin, is usually tough and more or less acid, so that it is disagreeable to remove the seeds, while in the European the pulp adheres to the skin, is tender and sweet throughout, and the seeds are easily removed. European grapes, when well grown, are valuable and agreeable for the use of invalids, and, undoubtedly, in the judgment of the majority of persons, surpass in quality any other fruit grown.

The subject of grape cultivation under glass may be divided under several heads, as follows: *The houses; The border; The vines; The fruit.*

The houses.

Houses are mainly of two forms, span-roof and lean-to, with occasional modifications between. Unless one has ample time and a desire to study their construction, it is better to have plans and estimates furnished by professional builders.

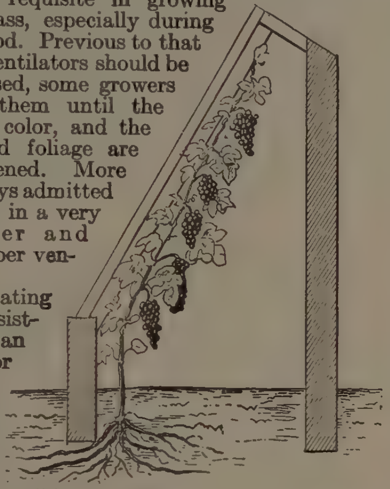
Span-roof houses are adapted to large places with spacious grounds, and especially where an ornamental effect is desired. On account of their exposure on all sides, they require very careful attention, especially if used for early forcing of grapes. When early work is not desired, or for use without artificial heat, their disadvantage is not so apparent. Houses without artificial heat, known as cold graperies, were in earlier years in more general use than those with heat, but have about disappeared with the introduction of the modern economical heating apparatus, and the very great advantage in the use of the same, if only to a limited extent.

Lean-to houses, on account of their snug construction and protection from northerly or prevailing winds, are especially desirable for early forcing of grapes (Figs. 1738, 1739). Often a stable or other building may be utilized for the north side, but generally a wall of brick or stone is erected for this purpose. Such a wall can be covered on the outside with *Parthenocissus tricuspidata*, or Crimson Rambler roses, producing a beautiful and ornamental effect. A good house, on a small scale, can be made of hotbed sash (Fig. 1739).

Foundations for the other three sides or for a span-roof vinery can be constructed of masonry or wood. Masonry is preferable, as the conditions of heat and moisture requisite are very destructive to woodwork, especially near the ground. With masonry, piers are erected, starting from solid ground and up to near the surface. They should be about 2 feet in length with spaces of 2 feet between, and opposite each space a vine is to be planted inside the house, as hereafter described. Strong capstones thick enough to come slightly above the surface of the border and about 18 inches wide are then laid from pier to pier. On such a foundation a superstructure can be erected with some confidence. For the base of the superstructure masonry is preferable, about 18 inches in height being necessary before the glasswork begins. A hollow wall, constructed of hard brick and cement, is desirable, and openings should be left for ventilation. The upper surface of these walls should be covered with cement. If constructed of wood, the same general plan should be carried out, using the most durable kind only.

Aside from its durability, masonry has an advantage over wood in being a better equalizer of temperature, and the heavy back wall of a lean-to house can be made of great value for this purpose. The general plans of the superstructure are shown in the illustrations. It should present as much glass surface as possible. The frame can be of iron or wood, as preferred. Light, heat and moisture are the great features desired, also a generous supply of air under favorable conditions. The glass should be of good quality, otherwise blisters will burn the foliage and fruit. Small ventilators should be built in foundation walls, and large ones at the upper part of house. A special ventilator covered with wire gauze is desirable for the lower opening. Ventilation should always be free from draft or sudden change of temperature. A draft is as unpleasant to a sensitive vine in a house as to a human being, and if subjected to it disease is sure to follow, mildew being the first evidence; and yet a generous supply of air is a prime requisite in growing grapes under glass, especially during the ripening period. Previous to that time the lower ventilators should be very carefully used, some growers never opening them until the grapes begin to color, and the new growth and foliage are somewhat hardened. More or less air is always admitted around the glass in a very equable manner and thence to the upper ventilators.

The modern heating apparatus, consisting of a boiler in an adjacent pit for heating water with circulating pipes throughout the house, as shown in illustrations, is a very perfect and economical supplier of heat, and it should be erected by a practical builder. A little heat at a critical time will often save a house full of grapes, and, while it can be dispensed with, its advantages are very material.



1739. Lean-to grapery glazed with sash.

It is possible to fruit grapes in benches in pots, removing the pots when the fruit is past, and using the house for other purposes (Fig. 1740).

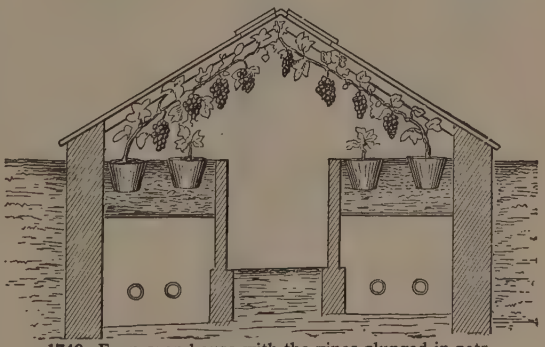
The border.

A good border is of great importance, as no permanent success can be obtained without it; probably the difference between success and failure more often lies here than in any other feature.

It is a good plan to construct vineries so that their borders can be somewhat elevated above the surrounding ground, as better drainage is thus secured, and good drainage is imperative (Fig. 1738). The border should fill the house inside and extend outside adjacent to where the vines are planted at least 6 feet when first made, and to this outside border additions should be made every two or three years of 2 to 4 feet until a width of 20 feet is secured. The border can hardly be made too rich, provided the material is well decomposed. A mixture of six parts good loamy turf from an old pasture or piece of new ground, and one part of well-prepared manure, one part old plaster or mortar, and one part of ground bone, all to be well composted together, will meet all the requirements. If the subsoil is clay, a foundation of old brick and mortar is very desirable to insure drainage. The border above this should be from 2 to 3 feet in depth. No trees or shrubs should be permitted to extend their roots into it, a very common cause of trouble, and nothing whatever should be grown on it, although the temptation to try a few melons or some lettuce is often too great to be overcome, and these probably do a minimum of damage. In such a border, if properly supplied with water, the vine roots will remain at home, and not go wandering off into trouble. When extra-early work is not desired, no attempt should be made to keep the frost entirely out of the border during the winter, as this is apt to result in a heavy, sodden surface in spring. It is better to spade it up roughly just before winter and cover with a good coat of manure, permitting the frost to enter the ground some inches. In the spring, it is dug over again and, when raked off, presents a rich, lively surface. The inside border is to be covered with a coat of well-rotted manure, and spaded up and well watered at the time of starting the vines. For midseason work from February 15 to March 1 is the proper time to do this in New York state, the inside border carrying the vines nicely until the outside border is in shape a month or more later. Then without hard forcing early grapes can be brought in by the last of June or July, and the later ones through the following two or three months. It is better to store late grapes in modern grape-rooms, where they can be kept fresh and plump for several months through the winter, than to attempt extra-early work by starting vines in heated borders in November and December.

The vines.

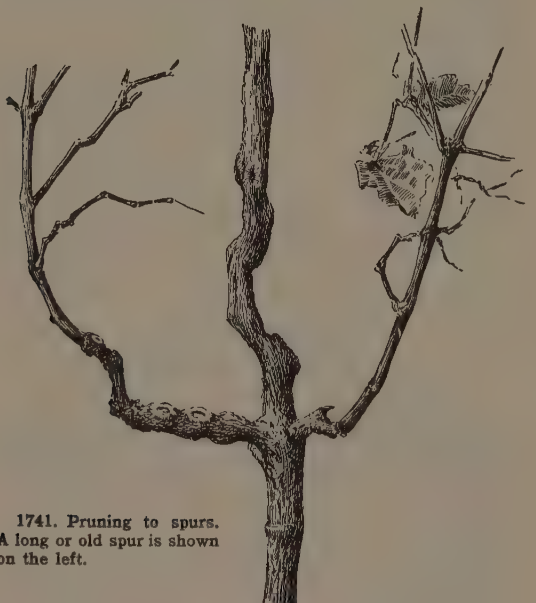
The amateur should purchase plants from some nurseryman of established reputation. Vines one or two years old are better than older ones. For supporting the vines light cast-iron brackets are secured to the rafters, and these support wires running lengthwise of the house about 15 inches from the glass, and to these wires the vines are tied as fast as they grow. The vines are to be planted inside the house about a foot from the front wall and about 4 feet apart, placing one opposite each opening in the foundation as before described. It is not desirable to plant them along the back wall of a lean-to house. They should be cut back to two or three buds near the ground, and when these start the strongest shoot only is selected for training and the others rubbed off. As this shoot advances it is tied to the wires and it may reach the limit of the house by July 1, or perhaps not until September 1, depending on the care, the vigor of the vine, and the border. Once there, the end is pinched and the cane continues to strengthen and increase in size and store up material in the lateral buds until the end of the season, when it is taken down and pruned to one-third its length, laid on the ground and covered from the sun for the winter. Care should be taken that mice do not eat out the buds, as once out they can never be restored. In the spring of the second year, or as soon as it is desired to start the vines, they are tied up again, and the terminal shoot again trained to the top of the house, where it is stopped as before. Any fruit appearing on this shoot should be removed. The lateral shoots that start out each way below the terminal should be thinned to about 12 or 15 inches apart on each side. This is an important feature, especially if one adopts the spur system of pruning, which will be first considered, for the vine is being established for a long term of years, and it is desirable to have it symmetrical, with the side shoots and fruit evenly distributed over its entire length. An example of a well-balanced vine is the illustration of the Muscat of Alexandria (Fig. 1743). A few clusters of fruit may be taken from this part of the vine this second year, and the



1740. Even-span house with the vines plunged in pots.

laterals should be pinched at two eyes beyond the cluster, and as they break pinched again through the season. As soon as the leaves fall the vines are again taken down for pruning. The terminal should be shortened about one-half and side shoots cut back to a bud very close to the main stem, when it goes through the winter as before.

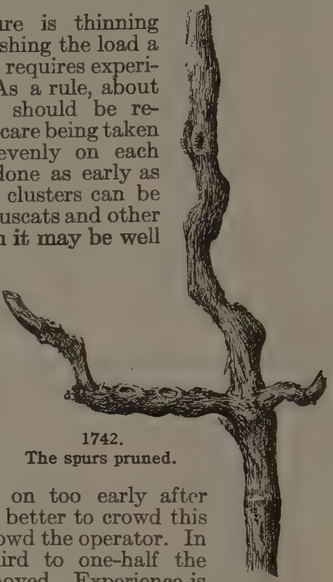
At the beginning of the third year, the terminal again goes to the top of the house without fruit, when it is stopped and the laterals are allowed to bear as before, say not more than one pound of fruit to a foot of the main stem. The vine is now established to the top of the house, and the only pruning in after years is to cut the laterals each year close to the main stem. A bud will nearly always be found in the first ⅛ inch, sometimes several of them. When these start, the strongest is selected and the others rubbed off, unless one is desired for training to the opposite side to fill a vacancy there. When the vines attain full strength, two pounds of fruit to the foot of main stem can be grown, but heavy loads require great care. Too heavy a load causes shanking, and then all is lost. The stems of the berries wither and the fruit turns sour before ripening. Rigid pinching of the laterals is very important. Commence at the second joint beyond the cluster, or about 18 inches from the main stem, and pinch thereafter as fast as new shoots break and show a leaf. Pinch early and often. It has been said that a good gardener can carry the summer prunings from a large vinery for an entire season in his vest-pocket. Some require a wheelbarrow. At the place where the laterals start, a spur soon forms on the main stem, from which the system takes its name. It often becomes several inches in length and quite ungainly. This spur system of pruning is represented in Figs. 1741–3.



1741. Pruning to spurs. A long or old spur is shown on the left.

In the other system of pruning, known as the "long rod" or "long cane" system, a new cane is grown up from a bud near the ground every year to replace the old one, which is entirely removed. It is sometimes desirable to replace an old cane fruiting on the spur system in this manner. If the vine is well established, this new cane can be fruited its entire length the first season, the laterals being pinched, as before described. It will produce finer fruit, but it is not so safe with a heavy load as an old cane.

An ample supply of water judiciously and freely used, especially at the time of starting the vines, is an absolute necessity. It should not be applied in the house, however, during the period of blossoming, as a dry air is advantageous for the transfer of the pollen for fertilization.



1742. The spurs pruned.

An important feature is thinning the clusters and establishing the load a vine has to carry. This requires experience and judgment. As a rule, about one-half the clusters should be removed,—often more,—care being taken to balance the load evenly on each side. This should be done as early as the general form of the clusters can be seen, except with the Muscats and other shy-setting kinds, when it may be well to wait for the berries to set, as some clusters set perfectly while others fail.

Thinning the berries should be attended to promptly, selecting cool days and mornings for this work. Close-growing kinds, like Alicante, cannot be commenced on too early after setting, and it is much better to crowd this work than to have it crowd the operator. In many varieties one-third to one-half the berries have to be removed. Experience is the only guide in this. A pointed stick is very useful with the vine scissors, and never touch the clusters with the fingers.

Tying up the shoulders of the clusters is necessary to permit a free circulation of air and light, otherwise the interior may decay, and, once started, the cluster is soon gone. The principal diseases or troubles to guard against are mildew and red-spider. The remedy for the former is sulfur, and for the latter moisture. Mildew is generally brought on by a sudden change of temperature. A vigorous condition of the vine has much to do in resisting it. Red-spider will almost always appear in the hot weather of July and August if the vines are allowed to become too dry.

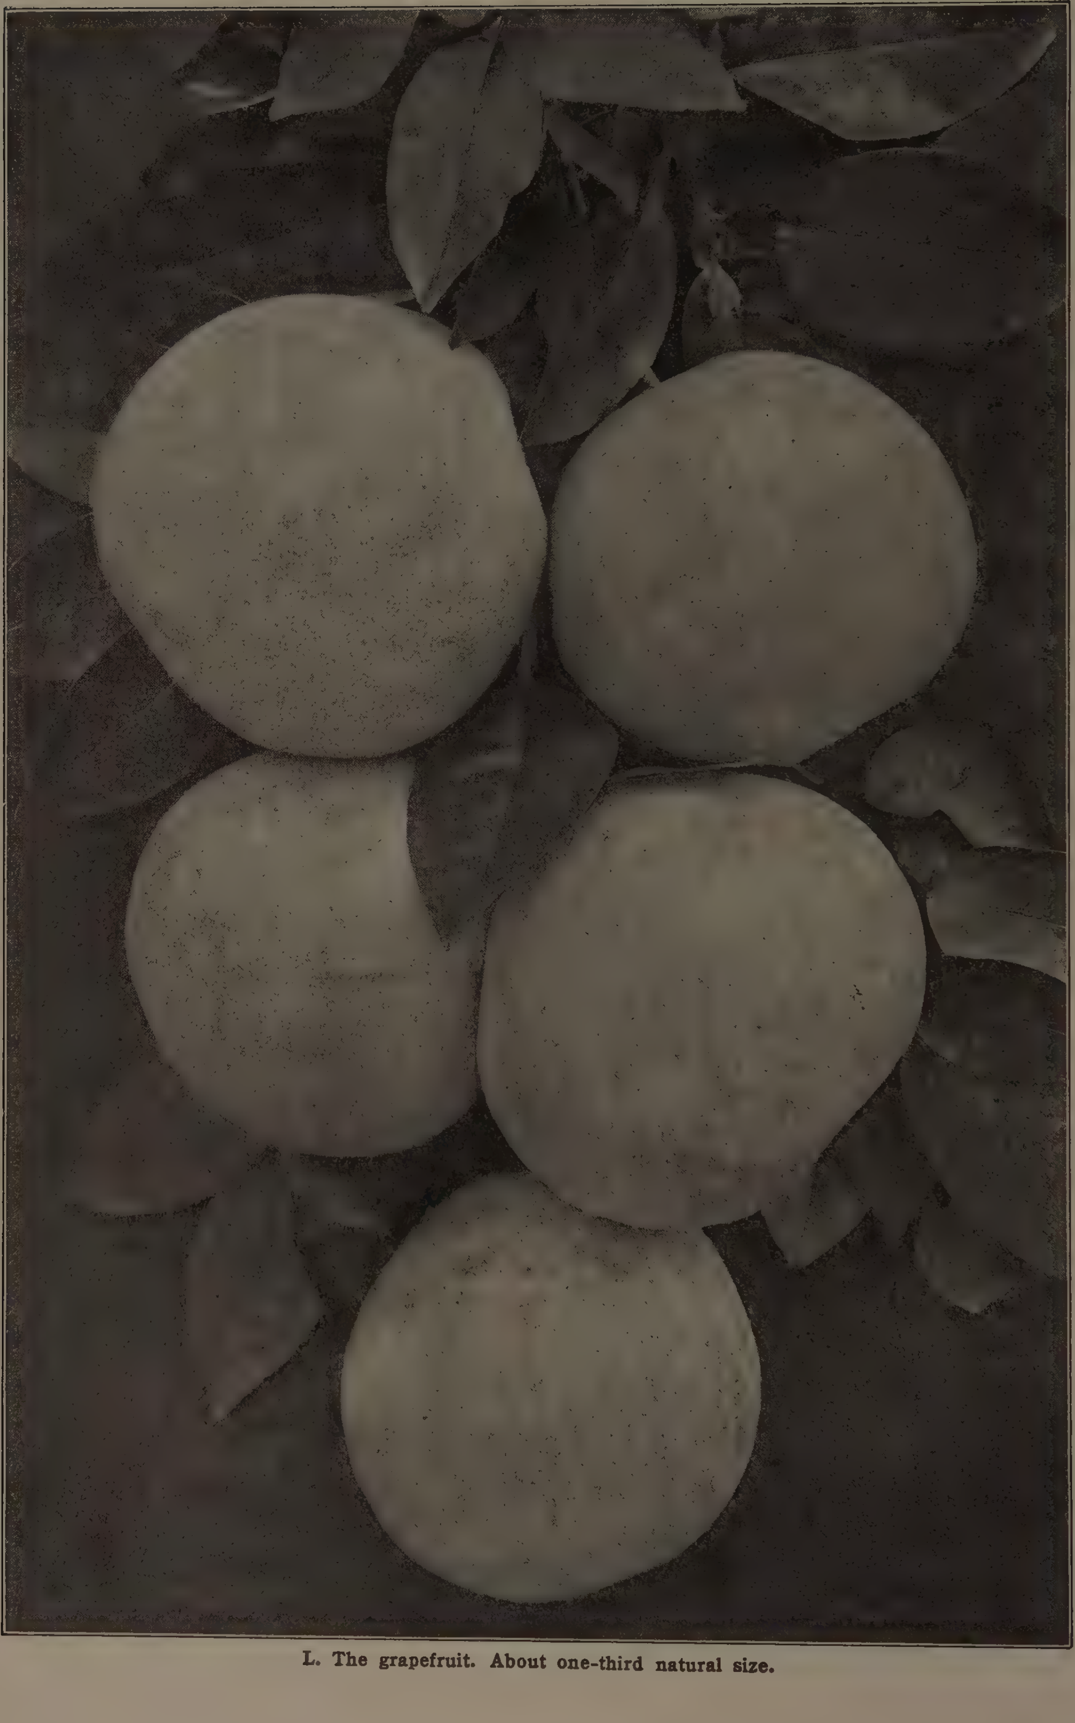
Thrips are sometimes very injurious, but can be controlled with nicotine, which, if properly applied, will not injure the fruit. Thrip and red-spider, if not taken in time, multiply rapidly, and "an ounce of prevention is worth a pound of cure" in these cases.

Perhaps, in a general way, the most important requisite of all is a large amount of enthusiasm and love for the work. This is necessary to insure the continued care and culture requisite to permanent success.

The fruit varieties.

As said before, very many varieties exist, but probably not one-half of these are in active cultivation at the present time. Varieties are adapted to localities, soils, climates, and the like. Perhaps fifty have been grown under glass in this country. Of these we will consider a few of the more prominent.

The Black Hamburg is more extensively grown and of more value for this purpose than all others put together, because it meets the requirements of the ordinary cultivator and will stand abuse and neglect and still give fair results, better than any other kind. It rarely gives very large clusters, but is a free bearer, sets fruit perfectly, will carry heavy loads and matures early. Under better care the appearance and improvement in quality is remarkable, and it can be made as good as the best. It is the variety with which the novice begins. Many houses consist entirely of Black Hamburgs, and many would give far better satisfaction if they did.



L. The grapefruit. About one-third natural size.

Muscat of Alexandria is the best of the white varieties for general cultivation. It requires a higher temperature and longer season than the Black Hamburgh to come to perfection, and will keep longer after cutting than that variety. When well grown and ripened it many be taken as a standard of quality. (See Fig. 1743.)

Muscat Hamburgh is a black grape, probably a cross between the two above-named varieties, and presenting marked characteristics of each. It has beautiful tapering clusters of fine quality.

Barbarossa is a good variety for those ambitious to grow large clusters and when well grown is of fine quality. It is a late black grape, requiring a long season to ripen well, but repays for the trouble by keeping thereafter for a long time. Clusters frequently grow to 8 or 10 pounds in weight, measuring about 24 inches each way, and they have been grown to more than double this weight.

Other large-growing varieties are the White Nice and Syrian, the latter of which is said to be the kind that the spies found in the land of promise. Clusters of 20 to 30 pounds weight are common to these two coarse-growing kinds, but their quality is so poor that they are now rarely grown.

Grizzly Frontignan is a beautifully mottled pink grape,—quite a deep pink sometimes,—and has long, slender clusters. In quality and flavor it is unsurpassed by any other grape, and it ripens quite early.

Royal Muscadine is an early white grape of fair quality and good habit quite common in English houses.

Gros Colman, a large black grape of fine quality and a late keeper, is now grown largely for commercial purposes in England and sent to this side to supply our wants in this line in spring. The berries frequently measure 4½ inches around, and it therefore requires early and severe thinning.

Alicante is a black grape of very distinct character, seeming to depart somewhat from the vinifera type, very juicy, and of fair quality. It has a very thick skin, and is about the best for long keeping.

1743. Muscat of Alexandria, bearing on spurs (as explained in Figs. 1741, 1742).

Lady Downs is another late black grape of good quality, but not adapted to all localities. Rose Chasselas, a small red grape, is the earliest and very beautiful. Trentham Black, the earliest black grape, has small clusters, but large, soft berries quite like Alicante. Foster Seeding is a beautiful midseason, amber-colored grape, with large clusters and berries sometimes liable to crack. Madresfield Court Muscat is a midseason grape—fine in quality, but also inclined to crack. This trouble can often be controlled by twisting or slitting the stems of the clusters, thereby checking the flow of sap.

D. M. Dunning.

GRAPEFRUIT (*Cítrus grándis*). *Rutaceæ.* Figs. 975, 1744. Plate L. A large globose fruit having slightly bitter acid pulp; it is used as a breakfast fruit and also for salads and desserts. It is grown in Florida, California, Arizona, and the West Indies, and is now extensively used by Americans. The name grapefruit, under which this fruit is known commercially, seems to have come from the West Indies and owes its origin to the fact that the fruits are often borne in clusters of three or four to twelve or more, much like a bunch of grapes. This fruit is also known as pomelo. The shaddock or pummelo is a distinct strain, not grown for commerce in this country. See *Citrus* (page 782) and *Pomelo*.

Grapefruit trees are large round-topped, with regular branches: lvs. dark glossy green, ovate with broadly winged petioles: spines slender, flexible, borne in the axils of the lvs.: fls. large, white, borne singly or in clusters in the axils of the lvs.; stamens 20–25; ovary globose, sharply set off from the style, which is deciduous: fr. pale lemon-yellow, flattened spheroid or globose, 4–6 in. diam., segms. 11–14, filled with slightly bitter acid pulp; seeds large, flattened and wrinkled; peel ¼–½in. thick, with numerous oil-glands.

The grapefruit appears to have been introduced into Florida by the Spaniards in the early part of the sixteenth century and until a quarter of a century ago it was grown only by the Florida pioneers. Since its culture has been undertaken on a commerical basis, the acreage planted to this fruit has rapidly increased, 1,061,537 boxes having been produced in Florida in 1909 as compared with 12,306 in 1899, and 122,515 boxes in California in 1909 as compared with 17,851 boxes in 1899. The total value of the crop in 1909, as reported by the Census, was over $2,000,000.

An excellent appetizer, the grapefruit is the most popular of breakfast fruits. It is also probable that it possesses valuable tonic properties, and it has been recommended by physicians in cases of malaria and biliousness. The sprightly flavor of the fruit, due to its slightly bitter principle, makes the grapefruit one of the most refreshing of all citrous fruits.

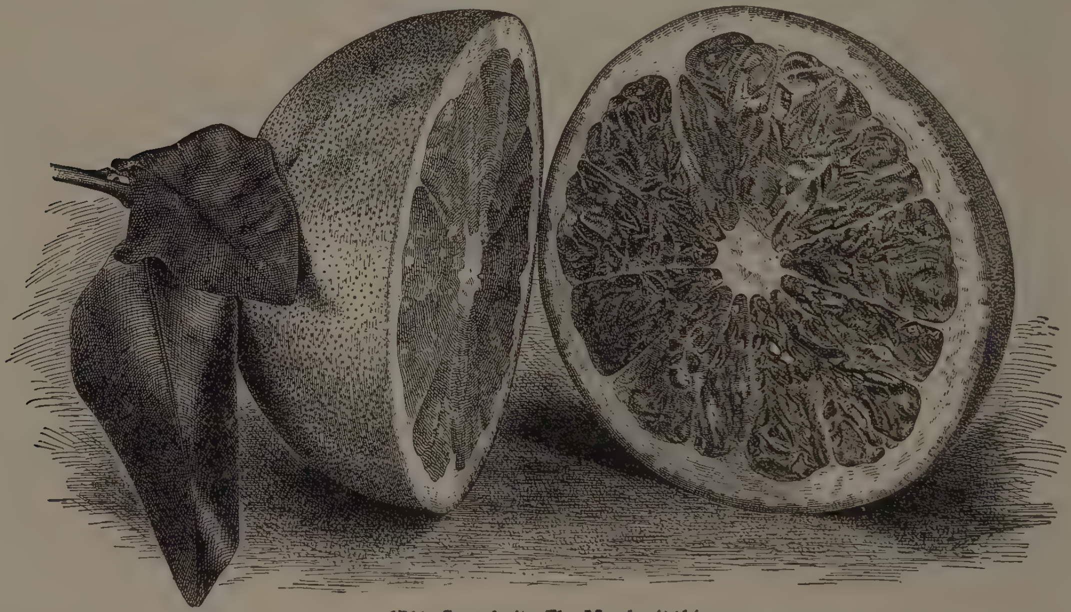
The grapefruit is more susceptible to cold than ordinary citrous fruits and its profitable culture is consequently restricted to regions below the frost line. The selection of a location is a matter of supreme importance in Florida where the occasional freezes have wrought so much damage in the past. The grapefruit, like most citrous fruits, prefers a light, well-drained soil, sandy or porous, though, because of its dense foliage, it grows better on poor soil than does the orange. The trees must be well fertilized in order to produce the best results, for it must be remembered that the care and fertilizer given are important factors in determining the quality and character of the fruit produced. Budded trees usually begin to bear in three to four years and generally reach full bearing in about ten years. They continue to bear for an indefinite period. The trees may be set from 18 to 25 feet apart, depending upon the stock on which they are grown. The seedlings make excellent stocks because of their well-developed root-systems and are extensively used for this purpose. They are hardier than the rough lemon but not so hardy as the orange. Grapefruits are usually propagated by budding because of the variations in the different varieties.

One of the most extensively grown varieties in Florida is the Duncan: fruits medium to large, oblate, light yellow; pulp a pleasant bitter acid flavor with few seeds; peel medium, firm; a late bearer, fruits keep well on the tree. The Duncan is one of the hardiest grapefruits, especially when budded on trifoliate orange stock (*Poncirus trifoliata*). Among others grown in Florida are Hall (Silver Cluster): fruits yellow, pleasantly bitter, globose, medium to large, in large bunches; a heavy bearer. Pernambuco: fruits large.

smooth-skinned. Introduced from Pernambuco, Brazil, by the United States Department of Agriculture. Triumph: fruits medium size, heavy, smooth-skinned, not very bitter; a prolific and a strong grower, but rather tender; season early. The Bowen, Excelsior, Josselyn, Leonardy, Manville, McCarty, McKinley, May, Standard and Walters are Florida seedlings cultivated locally in that state.

In California one of the best varieties is the Marsh (Marsh Seedless): fruit large (see Fig. 1744), subglobose, light yellow, not very bitter, often seedless, tree low and spreading. This variety originated in Florida but is best adapted to California conditions. The popularity of the grapefruit in California has been increasing during the past few years and it seems certain that this fruit is destined to become one of the standard fruits of that state. It should be noted that in California the grapefruit is really a summer fruit; in Florida it is a winter and spring fruit.

Hybrids.—The tangelo, the result of a cross between the tangerine orange and the grapefruit (pomelo) is a striking new citrous fruit. The Sampson tangelo, obtained by the writer in 1897 by crossing the tangerine with the Bowen grapefruit, is the first of this new group of fruits to be grown commercially. Other tangelos are now being tested. See *Tangelo.*



1744. Grapefruit—The Marsh. (×½)

Diseases.—The grapefruit tree is decidedly resistant to mal-di-gomma or foot-rot and is only slightly affected by scab. It is, however, more susceptible than any other citrous fruit to citrus canker. This disease was first discovered near Miami, Florida, in July, 1913, by E. V. Blackman. It is believed to have been introduced from Japan. In appearance somewhat similar to the scab, this disease has spread over a large area in southern Florida. It is very infectious and has been carried from one grove to another by wagons, birds, and other means. No remedy is known, and Florida growers, in order to check its spread, have been obliged to burn hundreds of infected trees. Investigators differ as to the cause of citrus canker. Walter T. Swingle.

Grapefruit, or pomelo, in California.

Pomelos have been grown for many years in California, but, although they succeed admirably, they have not been produced in a commercial way until within recent years. Even at present, the product is only a small fraction of that of the orange and lemon. Perhaps not more than 400 or 500 cars are annually shipped out of the state. All of the Florida varieties have been tested, many of them proving unsuited to the conditions. At present the Marsh, or Marsh Seedless as it is commonly called, is planted almost exclusively. The Triumph and the Imperial are also grown to some extent, while the Nectar and the Clayson are new varieties which are attracting attention.

But little attention has been paid to the handling of this fruit in California, and it is undoubtedly true that many of the seedling and miscellaneous varieties which have been inadvisedly put on the market have been very much inferior to Florida-grown pomelos. Usually, on account of the poor varieties grown, California pomelos are shipped mainly to Pacific and intermountain states where they do not come in such active competition with the Florida product. It is undoubtedly true, however, that certain varieties of the pomelo when well grown and intelligently handled are equal to the best Florida product. There is no reason why the production of pomelos in California should not be considerably increased. Growers, however, seem to fear an over-production and new plantings are at present quite small.

The pomelo, in its general growth, resistance to frost, propagation, culture, fertilizing, irrigation, and the like, is similar to the orange. The season in California is from February 1 until September 1. J. Eliot Coit.

GRAPE HYACINTH: *Muscari botryoides.*

GRAPE, SEASIDE: *Coccoloba uvifera.*

GRAPTOPHÝLLUM (Greek words referring to the variegated foliage). *Acanthàceæ.* Tender shrubs, one of which is cultivated in a very few American conservatories for its variegated foliage, and is said to be very popular in India and the tropics.

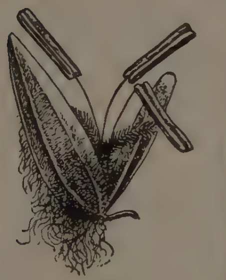
Leaves opposite, entire (in one species spiny-dentate), often colored: fls. reddish purple, wide gaping, clustered either in a terminal thryse or in the axils; calyx divided to the base into 5 segms.; corolla-tube inflated above; upper lip with 2 short recurved lobes; lower lip 3-cut; stamens 2: fr. a club-shaped or oblong caps.

—About 5 species, oriental. No two lvs. are marked exactly alike, but the yellow color is near the midrib rather than at the margins. The genus is close to Thyrsacanthus, but in Thyrsacanthus the fls. are not so distinctly 2-lipped. For cult., see *Justicia*.

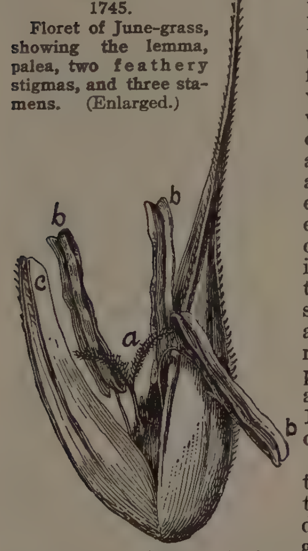
horténse, Nees (*G. pictum*, Griff. *G. picturàtum*, Hort. *Justícia pícta*, Linn.). CARICATURE PLANT. Height finally 6–8 ft.: lvs. elliptic, acuminate, irregularly marked with yellow along the midrib: fls. crimson, in axillary whorls; corolla pubescent. Habitat (?). B.R. 1227. Lowe 45. B.M. 1870 shows a variety with reddish brown coloring.—A yellowish-fld. form has been offered under the name *G. picturatum*, but it does not seem to differ otherwise. N. TAYLOR.†

GRASS (*Gramíneæ*). Annual or perennial, mostly herbaceous plants with usually hollow sts. (culms) closed at the joints (nodes), and 2-ranked lvs. Culms woody in the bamboos and in a few other groups such as the genus Lasiacis, sometimes solid as in maize: lvs. consisting of two parts, the sheath and the blade, the sheaths enveloping the culm above each node, the margins overlapping or occasionally grown together as in Bromus and Melica, the blades parallel-veined, usually linear or elongated (in some tropical grasses short and broad), on the inside bearing at the junction with the sheath a membranous or hyaline appendage or rim called the ligule; in some tropical grasses, especially bamboos, a petiole inserted between the sheath and blade: infl. paniculate or contracted into a raceme or spike, or more rarely into a head, the branches usually bractless; fls. usually perfect, sometimes monœcious as in maize, or diœcious as in salt-grass (Distichlis), small, without a distinct perianth, arranged in spikelets consisting of a shortened axis (rachilla) and 2 to many 2-ranked bracts, the lowest pair (the glumes) empty, one or both of these sometimes absent; each succeeding bract (lemma) including a single fl. and, with its back to the rachilla, a 2-nerved bract or prophyllum (palea), the fl. with its lemma and palea being termed the floret; stamens usually 3, with delicate filaments and 2-celled versatile anthers; pistil 1, with a 1-celled, 1-ovuled ovary, usually 2 styles and plumose stigmas: fr. a caryopsis with starchy endosperm, and a small embryo at the base on one side; grain (caryopsis) inclosed at maturity in the lemma and palea (or sometimes exceeding these as in maize and pearl millet), adherent to the palea as in the oat, or free as in wheat. Figs. 1745–1748 show the structure of various grass florets.

The lemmas are sometimes empty and are then termed sterile lemmas to distinguish them from the glumes. The spikelets may be inclosed in a spiny involucre or bur as in the sand-bur, or in an indurated shell as in Job's tears (Coix), or the entire spike in numerous husks as in maize.



1745. Floret of June-grass, showing the lemma, palea, two feathery stigmas, and three stamens. (Enlarged.)



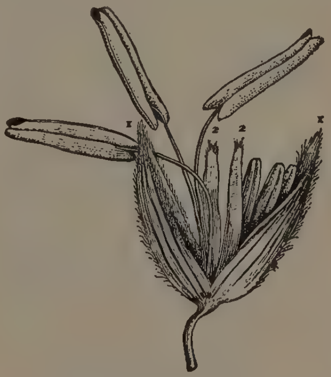
1746. Floret of a grass (rye). *cc*, lemma and palea: *a*, stigmas: *bbb*, stamens. (Much enlarged.)

The perennial species of grasses may produce creeping underground stems (rhizomes) by which they propagate. Kentucky blue-grass and awnless brome-grass are examples of this class. Such grasses usually form a sod. Those, such as orchard-grass, in which no rhizomes are produced usually grow in bunches or tussocks and are known as bunch-grasses.

The true grasses (*Gramineæ*) may be distinguished from other grass-like plants such as sedges (*Cyperaceæ*) and rushes (*Juncaceæ*) by the two-ranked leaves and the cylindrical or flattened stem. Sedges have three-ranked leaves and usually a triangular stem. There are also important differences in the floral structure.

A. S. HITCHCOCK.

1747. Spike of a grass (rye), containing many spikelets.



1748. Staminate spikelet of a grass (maize), showing two flowers, one of which (with three stamens) is expanded. 1, 1, glumes; 2, 2, palea. (Enlarged.)

Uses of grasses.

Among the species most commonly known are timothy, redtop, June-grass, orchard-grass, meadow foxtail, the fescues, oat-grass, sweet vernal, quack-grass, Bermuda-grass, sugar-cane, chess, and the cereals, such as wheat, barley, rye, oats, rice, sorghum, Indian corn. In number of species the grass family occupies the fifth place with 3,500, while the compositæ, legumes, orchids and madderworts are larger. In number of individuals, the grasses excel any other family. Seed plants are arranged in 200 to 220 families, and of all these the true grasses are of greatest importance; in fact, they are of more value as food for man and domestic animals than all other kinds of vegetation combined. None of these families is more widely distributed over the earth's surface, or is found in greater extremes of climate or diversity of soil.

The species are very numerous in tropical regions, where the plants are usually scattered, while in a moist, temperate climate, although the species are less numerous, the number of plants is enormous, often clothing vast areas. Where soil is thin or moisture insufficient, the grasses grow in bunches more or less isolated. Plants of one section of the family, Panicaceæ, predominate in the tropics and warm temperate regions, while plants of the other section, Poaceæ, predominate in temperate and cold regions.

Overstocking dry grazing districts checks the better grasses, destroying many of them, and encourages the bitter weeds which multiply and occupy the land.

A grass extends its domain by running rootstocks, by liberating seeds inclosed in the glumes which are caught by the breeze, by some passing animal, or the nearest stream; the twisting and untwisting of awns bury some of them in cracks, crevices or soft earth. In case a growing stem is thrown down for any reason, several of the lower nodes promptly elongate on the lower side and thus bring the top into an erect position. Each sheath supports and holds erect the tender lower portion of the internode, where it is soft and weak; it also protects the young branches or panicles. Thrifty blades of grasses suitable for pasture and lawn elongate from the lower end, so that when the tips are cut off the leaves do not cease to elongate, but renew their length. When exposed to sun or dry air, the blades develop a thicker epidermis, and, by shrinking of some of the delicate bulliform cells of the upper epidermis, they diminish their surface as they roll their edges inward or bring them together, like closing an open book. When the plant is in flower the minute and delicate lodicules become distended just in time to spread the glumes and liberate the stamens.

Grasses are not so much employed for ornamenting homes as their merits warrant. By selecting, some can be found suited to every week of the growing season, though many of them are in their prime during June, the month of roses. Wild rice (Zizania) is fine for rich soil in the margins of ponds, and masses of reed grass for deep beds of moist muck. For massing or for borders the following and others are stately: *Arundo Donax*, *A. conspicua*, maize, pampas-grass, Eulalia, ribbon-grass, *Andropogon formosus*, *A. halepensis*, Hystrix, Tripsacum. For glaucous blue-green, use *Elymus arenarius*, *Festuca glauca*, and *Poa cæsia*. For potting and borders, there are striped varieties of Dactylis, Anthoxanthum, *Holcus lanatus*, *H. mollis*, *Poa trivialis*, *Phleum pratense*, and others may soon be produced. For table decoration nothing is better than the elegant, airy panicles of large numbers of wild grasses, such as species of Poa, Kœleria, Sphenopholis, Panicum, Paspalum, Eragrostis, Muhlenbergia, Bromus, Festuca, Agrostis, Deschampsia, Uniola, Briza, *Cinna latifolia*. For large halls and exhibitions, nothing surpasses sheaves of wheat, barley, rice, oats or any of the wild grasses. For decoration, grasses should be cut before ripe, dried in the dark in an upright position, and may be used in that condition or dyed or bleached. For paths, nothing is more pleasing than strips of well-mown lawn.

Drainage keeps out sedges and encourages the better grasses; manure and irrigation help the best grasses to choke and diminish most weeds. Enough has already been done to show that rich rewards are sure for him who patiently and intelligently attempts to improve grasses for any purpose whatever by selection and crossing. Quack-grass is excellent for holding embankments; *Ammophila arenaria* for holding drifting sands. The grass family furnishes its full quota of weeds, among them quack-grass, crab-grass, chess, June-grass, sand-bur, stink-grass.

Turf-forming grasses are those that spread freely by creeping rootstocks, such as June-grass, quack-grass, Bermuda-grass, Rhode Island bent and redtop, while most others are more or less bunchy. For northern regions not subject to severe droughts, sow Rhode Island bent and June-grass both, or either one alone; for certain regions, which are liable to suffer from dry weather, sow June-grass and plant Bermuda-grass. These two on the same ground supplement each other in different kinds of weather, securing a green carpet during every part of each growing season. W. J. Beal.

GRASSES, POPULAR NAMES OF. Few grasses hold commanding positions as specimen plants, although the agricultural values of grasses are transcendent. Some of the commoner vernacular grass names (not all of true grasses) are given with references to the proper genera: **Animated Oats,** *Avena.* **Artificial-G.,** sometimes used for certain forage plants, as sorghum, but also leguminous plants, as clover, lucerne, sainfoin. **Awnless Brome-G.,** *Bromus inermis.* **Beach-G.,** *Ammophila arenaria.* **Bear-G.,** unusual name for *Yucca filamentosa.* **Beard-G.,** *Andropogon;* also *Polypogon monspeliensis.* **Bengal-G.,** *Setaria italica.* **Bent-G.,** *Agrostis.* **Bermuda-G.,** *Cynodon Dactylon.* **Blue-eyed-G.,** *Sisyrinchium.* **Blue-G.,** *Poa.* **Bluejoint-G., Bluestem-G.,** *Calamagrostis canadensis, Andropogon furcatus, Agropyron Smithii.* **Bog-G.,** *Carex.* **Bristly Foxtail-G.,** *Setaria magna.* **Brome-G.,** *Bromus.* **Canada Blue-G.,** *Poa compressa.* **Canary-G.,** *Phalaris canariensis.* **Cat-tail-G.,** *Phleum pratense.* **China-G.,** *Bœhmeria nivea.* **Citronella-G.,** *Cymbopogon.* **Cocksfoot-G.,** *Dactylis glomerata.* **Cotton-G.,** *Eriophorum.* **Couch-G.,** *Agropyron repens.* **Crab-G.,** *Eleusine* and *Digitaria sanguinalis.* **Crested Dog's-tail G.,** *Cynosurus cristatus.* **Deer-G.,** *Rhexia virginica.* **Dog's-tail-G.,** *Cynosurus.* **Eel-G.,** *Vallisneria spiralis.* **English Rye-G.,** *Lolium perenne.* **Esparto-G.,** *Stipa tenacissima.* **Feather-G.,** *Stipa pennata.* **Feather Sedge-G.,** *Andropogon saccharoides.* **Fescue-G.,** *Festuca.* **Finger-comb-G.,** *Dactyloctenium.* **Finger-G.,** *Chloris.* **Fly Away-G.,** *Agrostis hiemalis.* **Four-leaved-G.,** *Paris quadrifolia.* **Fowl Meadow-G.,** *Poa triflora.* **Golden-Top G.,** *Lamarckia aurea.* **Guinea-G.,** *Panicum maximum;* also erroneously used for *Holcus halepensis.* **Hair-G.,** *Agrostis hiemalis.* **Hare's-tail G.,** *Lagurus ovatus.* **Hassock-G.,** *Deschampsia cæspitosa.* **Herd's-G.,** in New England is timothy (*Phleum pratense*); in Pennsylvania, fiorin (*Agrostis alba*). **Holy-G.,** *Hierochloa borealis.* **Hungarian-G.,** *Setaria italica.* **Italian Rye-G.,** *Lolium multiflorum.* **Japanese Lawn-G.,** *Zoysia pungens.* **Job's-tears,** *Coix.* **Johnson-G.,** *Holcus halepensis.* **June-G.,** *Poa pratensis.* **Kentucky Blue-G.,** *Poa pratensis.* **Large Quaking-G.,** *Briza maxima.* **Little Quaking-G.,** *Briza minor.* **Love-G.,** *Eragrostis elegans.* **Lyme-G.,** of upholstery is *Deschampsia cæspitosa.* **Marram-G.,** *Ammophila arenaria.* **Myrtle-G.,** *Acorus Calamus.* **Oat-G.,** *Arrhenatherum elatius;* also various species of Avena. **Orchard-G.,** *Dactylis glomerata.* **Palm-leaved G.,** *Panicum sulcatum.* **Pampas-G.,** *Cortaderia.* **Pepper-G.,** *Lepidium;* also *Pilularia globulifera.* **Plume-G.,** *Erianthus Ravennæ.* **Pony-G.,** *Calamagrostis stricta.* **Purple Bent-G.,** *Calamovilfa brevipilis.* **Quack-, Quick-,** or **Quitch-G.,** *Agropyron repens.* **Quaking-G.,** *Briza.* **Rattlesnake-G.,** *Briza maxima;* also *Glyceria canadensis.* **Ray-G.,** *Lolium perenne.* **Redtop G.,** *Agrostis alba.* **Reed-G.,** *Arundo, Bamboo.* **Reed Bent-G.,** *Calamagrostis.* **Reed Canary-G.,** *Phalaris arundinacea.* **Rescue-G.,** *Bromus unioloides.* **Rhode Island Bent-G.,** *Agrostis canina.* **Ribbon-G.,** *Phalaris arundinacea* var. *picta.* **Rough Bent-G.,** *Agrostis hiemalis.* **Roughish Meadow-G.,** *Poa trivialis.* **Roughstalked Meadow-G.,** *Poa trivialis.* **Rye-G.,** *Lolium perenne.* **Sand-G.,** *Calamovilfa longifolia.* **Scurvy-G.,** *Cochlearia officinalis.* **Scutch-G.,** *Cynodon Dactylon.* **Seacoast Bent-G.,** *Agrostis alba* var. *maritima.* **Seneca-G.,** *Hierochloa borealis.* **Sesame-G.,** *Tripsacum.* **Sheep's Fescue-G.,** *Festuca ovina.* **Silk-G.,** *Agrostis hiemalis.* **Silver Beard-G.,** *Andropogon argenteus.* **Sour-G.,** local name for *Rumex Acetosella.* **Squirrel-tail-G.,** *Hordeum.* **Star-G.,** *Callitriche;* also locally for *Hypoxis* and *Aletris.* **Striped-G.,** *Phalaris arundinacea* var. *picta.* **Sweet-scented Vernal-G.,** *Anthoxanthum odoratum.* **Tall Meadow Oat-G.,** *Arrhenatherum elatius.* **Tickle-G.,** *Agrostis hiemalis.* **Tear-G.,** *Coix Lachryma-Jobi.* **Texas Blue-G.,** *Poa arachnifera.* **Timothy,** *Phleum.* **Tufted Hair-G.,** *Deschampsia cæspitosa.* **Vanilla-G.,** *Hierochloa borealis.* **Viper's-G.,** *Scorzonera.* **White Bent-G.,** *Agrostis alba.* **Whitlow-G.,** *Draba,* especially *D. verna,* and *Saxifraga tridactylites.* **Wood Meadow-G.,** *Poa nemoralis.* **Woolly Beard-G.,** *Erianthus.* **Worm-G.,** *Spigelia;* also *Sedum album.* **Yellow-eyed-G.,** *Xyris.* **Zebra-G.,** *Miscanthus sinensis.*

GRATÌOLA (Latin, *grace* or *favor*, from its reputed healing properties). *Scrophulariàceæ.* Low herbs, rarely planted.

Plants with opposite lvs.: fls. yellow or whitish, peduncled, axillary, hypogynous, perfect; calyx 5-parted, nearly regular; corolla gamopetalous, tubular-funnelform, more or less 2-lipped; upper lip entire or 2-toothed, lower 3-lobed; perfect stamens 2, the anterior pair wanting or rudimentary; ovary superior, 2-celled; style filiform; stigma dilated 2-lobed: fr. a 4-valved, many-seeded caps.—About 25 species in many parts of the world, none of which is of commercial importance. The following species has been advertised for sale and would make a good plant for covering the muddy borders of ditches and aquatic gardens. Most species are perennial.

aûrea, Muhl. GOLDENPERT. GOLDEN HEDGEHYSSOP. Annual, prostrate, viscid, puberulent or glabrate: lvs. lance-oblong, 2–12 lines long, denticulate, sessile by a broad base: fls. bright yellow, showy, 6–7 lines long. Wet sandy shores, Maine and Ont. to Fla., mostly along the coast. B.B. 3:162.

K. M. WIEGAND.

GRAVÈSIA (after C. L. Graves, who collected in Madagascar). *Melastomàceæ.* Dwarf warmhouse foliage plants, natives of Madagascar, and cultivated in a few American conservatories.

Flower parts in 5's or the stamens 10, all equal; petals obovate, obtuse or sometimes with a short spine-like process: fr. a 3-valved caps.—Three species. For cult. and for distinctions from allied genera, see *Bertolonia*, under which name most of the varieties are still known.

guttàta, Triana (*Bertolònia guttàta*, Hook.). Caulescent, erect: branches obtusely 4-angled: petioles 2½–3 in. long, densely scurfy-powdery: lvs. membranous, 5-nerved, rotund at base, slightly scurfy above and spotted, under side and calyx scurfy-powdery: cymes terminal, several-fld. Intro. 1865, and first described in B.M. 5524 as *B. guttata*, where the lvs. are shown with fairly well defined, double, longitudinal rows of roundish pink dots. F.S. 16:1696 is probably a copy of B.M. 5524. (See, also, Gt. 1865, p. 385, and B.H. 1865, p. 225.) Var. **supérba,** Hort., I.H. 26:359 (1879), is shown, with more and larger reddish purple spots, which are less regularly arranged. Var. **Legrelleàna** (*B. Legrelleàna*, Van Houtte). An alleged hybrid obtained by Van Houtte and figured in F.S. 23:2407. Coigneux refers this plate to *Gravesia guttata*, but no fls. are shown, nor have the lvs. any spots. The nerves are outlined in white, and some of the cross-veins for short distances. Var. **Alfred Bleu** is brilliantly spotted and lined with bright red, the nerves boldly outlined, the cross-veins interruptedly outlined. I.H. 41:13 (1894). Var. **margaritàcea,** Nichols. (*B. margaritàcea*, Hort. W. Bull=*Salpinga margaritacea.* F.S. 16:1697). See DC. Mon. Phan. 7:537.

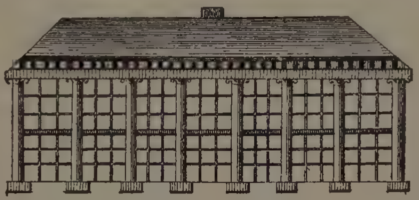
N. TAYLOR.†

GRAVÌSIA (the name unexplained). *Bromeliàceæ.* South American acaulescent herbs, differing from Æchmea in the character of the pollen-grains and other technical features, and requiring similar treatment in cult. Lvs. densely rosulate, conspicuously sheathing, brown-scurfy, the margin more or less spiny: scape arising from the center of the rosette, bearing a panicled or bipinnate infl.: petals yellow or orange. **G. exsûdans,** Mez (*Æchmèa exsùdans*, Baker. *Tillándsia exsùdans*, Desf. *Bromèlia exsùdans*, Lodd. *Hohenbérgia capitàta*, R. & S.) Fls. congested in sessile heads composing a compound panicle, the floral bracts spine-pointed: lvs. whitish beneath, oblong, spiny. L.B.C. 9:801.—Fls. said to exude a whitish greasy substance, whence the name. Plant 2–3 ft. Apparently very little grown.

L. H. B.

GREENHOUSE. In America the word greenhouse is used generically for any glass building in which plants are grown, with the exception of coldframes and hotbeds. Originally and etymologically, however, it means a house in which plants are kept alive or green: in the greenhouse plants are placed for winter protection, and it is not expected that they shall grow. The evolution of the true greenhouse seems to have begun with the idea of a human dwelling-house. At first larger windows were inserted; and later, a glass roof was added. In early times it was thought best to have living-rooms above the greenhouse, that it might not freeze through the roof. Even as late as 1806, Bernard M. Mahon, writing in Philadelphia, felt called upon to combat this idea. The old or original conception of a greenhouse as a place for protecting and storing plants is practically extinct, at least in America (Fig. 1749). In England, the word greenhouse is mostly used for a house or structure in which are kept or grown those plants that do not require a very high temperature.

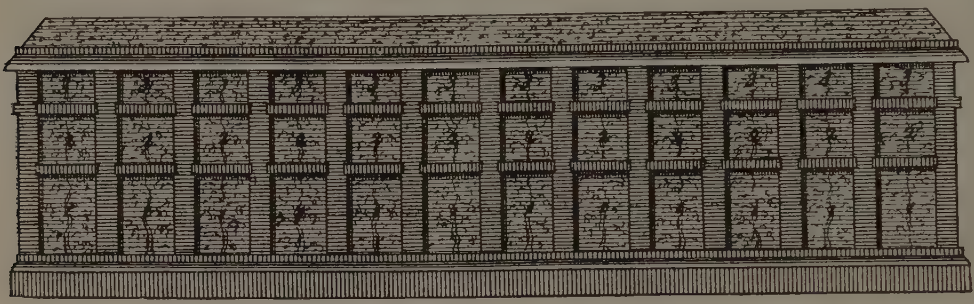
Other types of plant-houses are the conservatory (which see), in which plants are kept for display; the forcing-house (see *Forcing*), in which plants are forced to grow at other times than their normal season; the stove or warmhouse; the propagating-pit. Originally the warmest part of the plant-house, that part in which tropical plants were grown, was heated by a stove made of brick, and the house itself came to be called a stove. This use of the word stove to designate the warmest part or room of the range is general in England, but in America we prefer the word warmhouse (and this word is much used in this Cyclopedia). Originally, hothouse was practically equivalent to stove, but this term is little used in this country, and when used it is mostly applied generically in the sense of greenhouse.



1749. The old-time greenhouse with opaque roof and sash-made sides (Abercrombie, 1786).

It will thus be seen that there is no one word that is properly generic for all glass plant-houses. The word glasshouse has been suggested, and it is often used in this work; but there are other glass houses than those used for plants. It seems best, therefore, to use the word greenhouse for all glass buildings in which plants are grown; and American usage favors this conclusion.

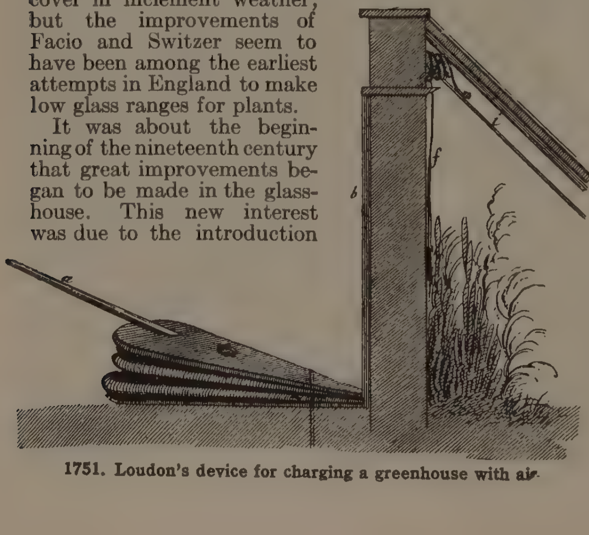
The long, low greenhouse range, of the type we now know in our commercial establishments, probably had a different origin from the high-sided greenhouse. The glasshouse range appears to have developed from the practice of protecting fruits and other plants against a wall. In European countries, particularly in England, it is the practice to train fruits and other plants on stone or brick walls, that they may be protected from inclement weather and receive the greater sun heat that is stored in the masonry. It occurred to Nicholas Facio Duilhier to incline these fruit walls to the horizon so that they would receive the greater part of the incident rays of the sun at right angles. He wrote a book on the subject of "Fruit-Walls Improved," which was published in England in 1699. Facio was a mathematician, and he worked out the principle of the inclined walls from mathematical considerations. Such walls were actually built, but according to the testimony of Stephen Switzer, who wrote in 1724, these walls were not more successful than those which stood perpendicularly. Certain of these walls on the grounds of



1750. Switzer's glasshouse, built on an inclined wall (1731).

Belvoir Castle, and over which grapes were growing, received the additional protection of glass sash set in front of the inclined walls and over the vines. In addition to this, flues were constructed behind the wall in which heat might be supplied. The construction of hollow heated walls was not uncommon in that day. The satisfactory results that followed this experiment induced Switzer to design glass-covered walls. The "glasshouse" which he pictured in the "Practical Fruit-Gardener" (1731) represents a greenhouse 3½ feet wide in the clear (Fig. 1750). At the back of this house is an inclined heated wall on which the grapes are grown. Three and one-half feet in front of this a framework is erected to receive the sash. There are three tiers of openings or windows along the front, the two lower ones of which are for window-sash, and the upper one is vacant in order to provide for ventilation and to allow space to receive the lower sash when they are lifted up. The whole structure is covered with a roof or coping. Switzer declares that the introduction of these covered sloping walls "led the world" to the "improvement of glassing and forcing grapes, which was never done to that Perfection in any Place as it is upon some of the great Slopes of that elevated and noble Situation of *Belvoir Castle.*" Johnson, in his "History of English Gardening," quotes the remarks of Switzer, and makes the statement that the use of these walls "led to the first erection of a regular forcing structure of which we have an account." The immediate outcome of these covered walls seems to have been the lean-to greenhouse, and from that structure has perhaps developed the double-span glass range of the present day. Long before Switzer's time plants were forced in a crude way, even by the Romans, mostly by being placed in baskets or other movable receptacles, so that they could be placed under cover in inclement weather; but the improvements of Facio and Switzer seem to have been among the earliest attempts in England to make low glass ranges for plants.

It was about the beginning of the nineteenth century that great improvements began to be made in the glasshouse. This new interest was due to the introduction of new plants from strange countries, the improvement of heating apparatus, and the general advance in the art of building. The ideals that prevailed at the opening of the century may be gleaned from J. Loudon's "Treatise on Several Improvements Recently Made in Hot-Houses," London, 1805. One of the devices recommended by Loudon will interest the reader. It is shown in Fig. 1751. The bellows is used for the purpose of forcing air into the house, that the plants may be supplied with a fresh or non-vitiated atmosphere. "By forcing the air into the house, once a day or so, double the quantity of air which the house usually contains" can be secured. The house could be "charged." The tube leading from the bellows is shown at *b;* it discharges at *c.* Curtains run on wire, *i;* the curtain cord is at *f.*



1751. Loudon's device for charging a greenhouse with air.

Greenhouses are now built on the plan of the long low glass range with sides varying from 5 feet 6 inches to 7 feet in height. The tendency in commercial structures is for a height of 7 feet from ground to eaves. The taller glass structures are used for conservatory purposes, housing such table plants as palms, tree-ferns, or the like, or when an architectural feature is desired. The general tendency of the building of glass structures is toward extreme simplicity (Fig. 1547, p. 1256). In the extreme South, lattice-work buildings are sometimes used for the protection of plants, both from light frosts and from the sun (Fig. 1752). The heating now employed in this country is of three different kinds: hot water under very low pressure or in the open-tank system; hot water in practically closed circuits; and steam. Hot water under low pressure is an old-time mode of heating, and is not now popular in this country except for conservatories and private establishments. The heavy cumbersome pipes are not adapted to laying over long distances and under varying conditions. The commercial houses are now heated by means of wrought-iron pipes, which go together with threads. The comparative merits of steam and hot water in these wrought-iron pipes are much discussed. For large establishments, hot water under pressure is now employed to some extent. Much progress has been made in methods of heating in recent years, and either steam or hot water gives good results when competently installed. The merits of one system or the other are very largely those of the individual establishment and apparatus, and the personal choice of the operator (see page 1403; also pages 1400 and 1402).

The simple straight and direct house is now much in favor with the commercial growers of carnations, chrysanthemums, violets, roses, vegetables, and with propagators. Most of the greenhouse construction firms are designing houses most admirably adapted to the growing of these plants. Each firm has a few original forms worked into the detail plans, calculated to appeal to the growers' fancy. Perhaps the ideal structure for carnations, for example, is a single detached house, about 50 feet wide and 500 feet or less in length, with ventilators on each side of the ridge and on each side below the eaves, and the eaves, or the gutters, 6 feet above the grade.

With the refinements of architecture and the growth of satisfaction in home-building, the glasshouse is becoming an integral part of the residence. Sometimes it takes the form of a sun-parlor, and in which certain plants may be kept at least temporarily; sometimes it is a real plant-house added to the residence, a glass or covered garden that carries bloom and verdure through the cold weather and enables the homemaker to span the year. The best results in plant-growing are secured when the structure is separate, with its own heat, its normal exposure, and its own essential set of conditions; but it is worth while to add a garden-room to a residence even if the horticultural results are not great. Some of the architectural combinations of glass and other materials are very artistic and interesting.

L. H. B.

Greenhouse construction.

For convenience, this subject may be considered under the following heads; i. e., *Location, Plans, Grading, Foundations, Framework, Glazing and painting, Plant-tables, Ventilation, Heating.*

Location.

Greenhouses which are intended for use in connection with the gardens should be placed, for convenient attendance, within the garden inclosure or along its boundary. A good location for the garden will usually be found the best one for the greenhouse.

A conservatory or greenhouse designed for a private place, where specimen and blooming plants will be kept for the pleasure of the family and entertainment of visitors, should be attached to the dwelling or located as near as possible in a well-kept part of the grounds. A conservatory does not require a full southern exposure. Most decorative plants thrive as well or better and continue in bloom for a longer time if kept in a house having plenty of light, but so located as to receive but little direct sunlight. Large ranges of glass adapted to a variety of purposes are generally kept separate from other buildings. In parks the location should be near a main entrance.

The location of a range of glass for commercial purposes, where the elements of expense and profit are to have the first consideration, is of great importance. The chief items that determine the desirability of a suitable location are the adaptability and value of the land, cost of fuel delivered, ample and inexpensive water supply and proximity to a market. The top of a bleak hill and the bottom of a valley should both be avoided. Level land, or that having a southerly slope, is the best.

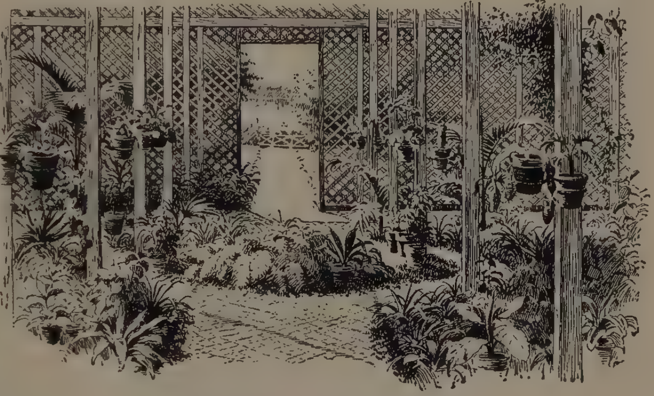
Plans.

When a site for the proposed greenhouse has been decided upon, full plans should be made before commencing to build. The plans should embrace not only the glass, which is required at once, but should provide for the largest increase which can be anticipated. In this way houses can be erected which are convenient to work and have a good appearance, with small extra cost for building only part at a time. Attention should be given to the special peculiarities of the location, like the exposure to the sun, grade of ground, shape of lot and best location for the heating apparatus. Each compartment should have the proper form of house and exposure to the light adapted to the plants for which it is provided.

It will readily be seen that to locate and plan a range of glass to the best advantage requires skill and experience. In a communication received by the writer from a superintendent of one of the most important botanic gardens in the country, it was remarked that "when the architect prevails, the gardener fails." It is also true to a greater degree than in almost any other class of buildings that the beginner or amateur who undertakes to plan and construct his own greenhouse is likely to pay well for his experience, and will at least sympathize with the "lawyer who pleaded his own cause and found he had a fool for a client." This is perfectly true, as many know to their cost. To plan a greenhouse satisfactorily, the designer must have a practical knowledge of the requirements. To meet this increasing demand, specialists can be found, known as "horticultural architects," who devote their entire time to this branch of work.

Grading.

The floor of the greenhouse should be a few inches above the outside grade. As most greenhouses are necessarily built low to accommodate the plants, a small terrace around them adds to the elevation and the good appearance of the structure. It will usually be best to keep the floor of a greenhouse all on one level. When the variation in the grade of the ground is not too great, the floor line should be at the highest point of the grade. In the case of a long house, the floor line is sometimes made the same as the natural grade, but such an arrangement is to be avoided when possible. For locations on a hillside, the different apartments may have different floor-levels, with necessary steps between them.



1752. A lattice-covered plant-house.

All the sod and loam should be removed from the space to be covered by a greenhouse and all the filling necessary made with subsoil. The latter should be laid in thin layers and each wet down and thoroughly tamped. Loam used for filling under a greenhouse is likely to become sour, and will continue to settle for a long time, causing much trouble and annoyance.

Foundations.

Too much care cannot be given to the preparation of good foundations. These are usually of brick, but may be made of stone or concrete. The brick walls take up less room in the house than stone, and are usually less expensive. The foundation walls should be extended down to a point below the frost line, generally 3 or 4 feet deep, and are usually raised about 2 feet above the grade. An inexpensive wall of rubble stone work or of concrete is all that is needed in the ground. The part of the wall showing above grade may be of plain brick, or brick faced with stone, or the entire wall may be built of concrete finished with cement plaster. It is usual to construct the walls of the same material as the surrounding buildings, or with some material that will harmonize with them. Until a few years ago, double boarding was used exclusively for the side walls in greenhouses built by florists, the rafters being carried into the ground about 30 inches. Today, light concrete walls about 4 inches thick are built. The cost of the concrete is almost the same as double boarding but has the advantage of being indestructible.

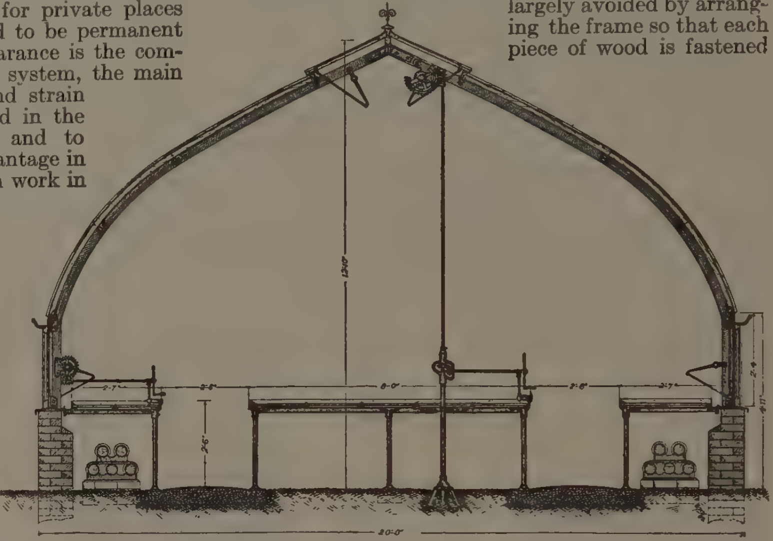
Framework.

The construction best adapted for conservatories, park houses and greenhouses, and for private places where the improvements are desired to be permanent in character and attractive in appearance is the combination of iron and wood. In this system, the main frame which supports the weight and strain is of iron, or steel, wood being used in the frames as a setting for the glass and to form a non-conductor of great advantage in the heating of the house. The iron work in this style of construction usually consists of cast-iron sills capping the foundation walls, wrought-iron rafters setting on the sills, about 8 feet apart and running from sill to ridge, forming the side post and rafter in one piece, cast-iron gutters, and angle iron purlins between the rafters, all securely bracketed and bolted together, forming a complete framework of metal, light, strong and durable. The wood used consists of light sash-bars for supporting the glass, sashes for ventilation and doors. This woodwork being entirely supported by the metal frame, and not being used where it will be continually wet, will be found as durable as any other material, and for many reasons better adapted for the requirements of a greenhouse roof. This combination system of metal and wood construction has been extensively adopted by florists, growers of cut-flowers and also the progressive vegetable-growers. In the houses built for the above, the masonry foundation walls are omitted. Posts constructed of wrought-iron are placed in the sides extending from about 30 inches below grade to the height of the eaves. These posts occur at every rafter, to which they are connected with steel or cast-iron fittings. The posts are embedded in concrete below grade, and 4-inch concrete walls built extending from 6 inches below grade up to the under side of the glazing sill.

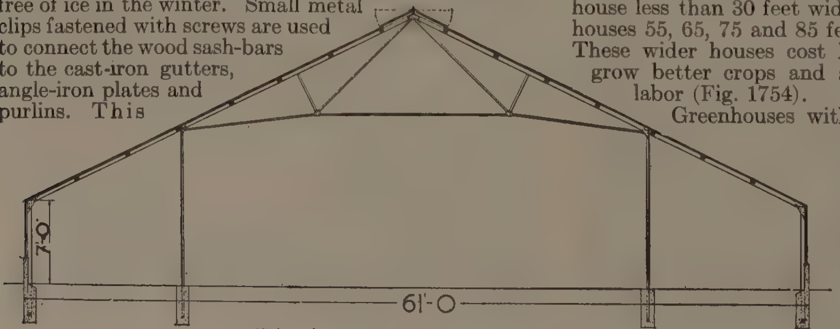
Gutters are seldom used at the eave line in this type of house. An angle-iron eave-plate is substituted for the gutter so framed as to allow the snow and ice to slide over it, keeping the roof entirely clear from such accumulations which darken a house in winter.

The first cost is somewhat increased over an all-wood construction, but in view of its greater durability and saving in repairs, it will be found in the end, the better investment.

Cast-iron gutters are provided to collect the rain-water from the roof. By exposing the inner side of these gutters to the heat of the house, they are kept free of ice in the winter. Small metal clips fastened with screws are used to connect the wood sash-bars to the cast-iron gutters, angle-iron plates and purlins. This method of securing the sash-bars in place is very convenient in case of repairs, and renders the structure practically portable. A careful examination of any old greenhouse will show that the parts of the frame which decay first are those pieces of wood which are joined together, for water penetrating the joints soon destroys the wood. This trouble is largely avoided by arranging the frame so that each piece of wood is fastened directly to the iron frame instead of to another piece of wood. Joints between wood and iron do not rot the wood, the latter being preserved by the corrosion of the metal.



1753. Even-span curvilinear greenhouse, with cast-iron piping.



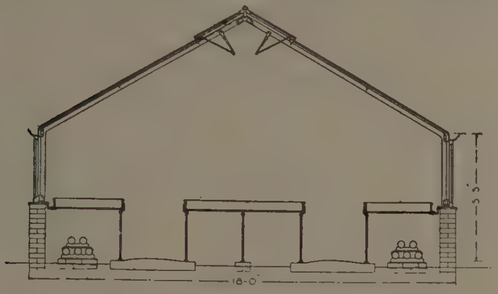
1754. A very wide plant-grower's house.

The curvilinear form of house (Fig. 1753) is ornamental and particularly well adapted for conservatories, palm-houses and show-houses of all kinds. It is preferred for vineries and fruit-houses, as the form allows the canes to be supported on the line of the roof without a sharp bend at the plate line. The light in a curved house, being admitted at different angles, is better diffused and more natural than when reflected through a long pane of straight glass. The cost of a curved roof is slightly greater in the construction, but the arched frame is stronger and will keep its shape better than a house with straight lines, thus largely compensating for the extra cost. For special purposes and locations, special forms of frames may be used. Good forms of commercial houses are shown in Figs. 1754–56.

The ridge-and-furrow type of house (Fig. 1757) is seldom built now except in cases in which the amount of land available is limited. The superior growing qualities of greenhouses built separately has been thoroughly demonstrated, as has also the increased productiveness of wide houses. A florist now seldom builds a house less than 30 feet wide. It is oftener 40 feet, and houses 55, 65, 75 and 85 feet wide are not uncommon. These wider houses cost less in proportion to build, grow better crops and are more economical as to labor (Fig. 1754).

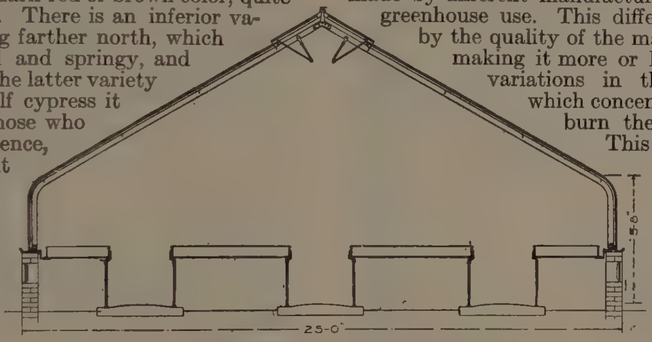
Greenhouses with curved eaves (Fig. 1756) are being built more and more. This type presents a pleasing appearance and eliminates shade-casting members at the eaves. A combination sill and gutter is substituted for the plain sill on top of masonry wall to which the rafters and bars are secured.

It is commonly admitted that the so-called "sash-bar construction" is not the best or lightest method of construction, but as the absence of most of the framing reduces its cost so that it is the cheapest to build, it remains a popular method of putting up a commercial greenhouse. Circulars showing the various methods adopted by the dealers in greenhouse material can readily be secured by applying to them.



1755. A compact two-walk house.

The best wood to use for greenhouse framework and plant-beds is undoubtedly cypress. In purchasing this lumber, care should be taken that only that grown in the states bordering on the Gulf of Mexico be selected. This will be found of a dark red or brown color, quite soft and easily worked. There is an inferior variety of cypress growing farther north, which is light in color, hard and springy, and likely to be shaky. As the latter variety is cheaper than red Gulf cypress it is frequently used by those who do not know the difference, to the serious detriment of the work and the loss of reputation of cypress for such purposes.



1756. Section of curved-eave house.

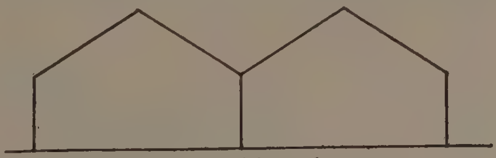
In the market there are three grades of cypress lumber, and it is important to know which to choose. The best grade is known as "firsts and seconds," and calls for lumber with a small extent of sap on the edges and occasionally a small sound knot. This is the quality which should be ordered for all the framework of the roof, sash-bars, and so on. In order to make the material entirely free from sap there will be a waste in cutting up this quality of 10 to 20 per cent. The second grade is known to the trade as "selects." This name indicates that it has been graded so that one face of each piece of lumber is of about the same quality as the "firsts and seconds," the other face generally being largely sap. This quality is fit only for outside boarding in greenhouse construction; it has too much sap. The cost is usually about five dollars a thousand less than the best grade. As it looks to the inexperienced eye almost the same as the best grade, too much of it finds its way into greenhouse structures. Such sap lumber usually will not last more than two to five years. Too great care cannot be exercised to avoid its use. The third grade of cypress lumber is termed "cutting up," and is so called because it embraces all the pieces which have imperfections, such as large knots and splits, which bar them from the better grades. This is a good quality to purchase for base-boards and plant tables, for by cutting out the sap and objectionable knots it will be found satisfactory for these purposes. The "cutting up" grade costs about ten dollars less a thousand than the "firsts and seconds." The percentage of waste in cutting up will be somewhat greater than in the other grades. Cheap timber is likely to give unsatisfactory results in greenhouse work.

Cypress lumber which has been in use for gutters, sash-bars, plates, and the like, in greenhouses where high temperatures have been maintained is still, after many years, apparently in as good condition as when first used. Owing to the porous texture of the wood, the paint, when applied, sinks in and does not make so fine a coat as on some other woods, but because of this fact the paint adheres to the wood better and lasts longer.

Glazing and painting.

Ordinary sheet or window glass is in general use for greenhouse glazing. It is better to use only the thickness known to the trade as "double-thick." This weighs from twenty-four to twenty-six ounces a square foot. The thickness known to the trade as "single thick" weighs only about sixteen ounces to the square foot, and is entirely too frail for the purpose. There is very little difference at present in the quality of the imported French or Belgian and the American glass. The weight of most of the glass of American manufacture is about 2 ounces greater a foot than the imported, and therefore it is proportionately stronger. This greater strength is of considerable importance in the additional security which it affords from damage caused by that enemy of the florists, the hail-storm. There is a great difference in the quality of the glass made by different manufacturers in its adaptation to greenhouse use. This difference is caused chiefly by the quality of the material used in the glass, making it more or less opaque, and in the variations in thickness causing lenses which concentrate the sun's rays and burn the foliage of the plants. This last defect in the glass cannot be wholly guarded against, as the product of a factory does not always run the same so that any favorite brand cannot be fully relied upon in this respect. The waves which burn will be found in all the different grades of glass, firsts, seconds and thirds, with little, if any difference, the grading being done chiefly for other defects, such as affect the value of the glass for window purposes. For these reasons, in selecting the glass for a greenhouse, it requires experience to decide what make of glass it will be best to purchase. It will be well to purchase from someone who makes a specialty of furnishing glass for greenhouses or call in the aid of some friend who has had experience in building, and can give intelligent advice.

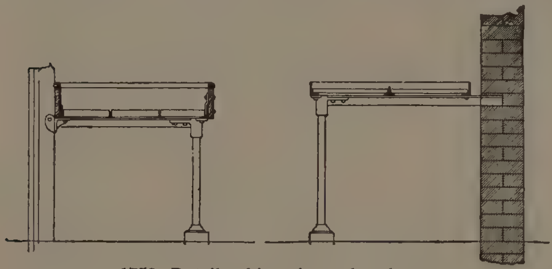
The second quality of glass is usually selected for the best greenhouse work. The standard widths are from 12 to 16 inches, and lengths vary from 16 to 24 inches. A favorite size is 16 by 24 inches. This is about as large as it is practicable to use double thick glass, and makes a roof with comparatively few laps.



1757. Ridge-and-furrow houses.

It is not safe to purchase fourth quality of glass or the so-called "greenhouse glass" frequently offered by window-glass dealers, as both of the grades contain the culls and lights only fit to glaze cheap sash for market-gardeners, and is of doubtful economy even for this purpose. Rough plate and ribbed glass is used on large palm-gardens and conservatories in which the maximum of light is not an essential feature. Where this glass is used larger roof-bars are needed and stock construction has to be materially changed. Recently a few conservatories have been glazed with thick, polished plate-glass, making very handsome roofs, but rather expensive.

To set glass properly in a greenhouse roof, it should be bedded in the best putty on wood sash-bars and lapped at the joints. The bars should be spaced accurately, so that the glass will fit the rabbets with not over $\frac{1}{16}$ of an inch allowance, and the panes of glass should lap each other not more than from ⅛ to ¼ of an inch. Zinc shoe-nails fasten the glass best, using from four to six to each pane, according to the size of the light. No putty should be used on the outside of the glass. A comparatively new system of glazing has been adopted by some florists in which no putty is used, but the glass is placed directly on the rabbets of the bars and the ends of the panes are butted together and held in place by wood caps fastened to the sash-bars. This system does not make a tight roof, allowing considerable water to enter the house through the joints, nor does it provide any means of escape for the condensed water from the under side of the glass, which is a very serious objection. In ordinary glazing, where each light laps over the one below, the condensed water passes through the joints to the outside, forming a perfect remedy for this trouble. The difference in the cost is very slight, if anything, provided the work is equally well done, as the value of the putty omitted is fully offset by the extra cost of the caps.



1758. Details of iron-frame benches.

The painting of a greenhouse roof is a very important part of the work. Owing to the extremes of heat, cold, dryness and moisture to which it is exposed, the conditions are decidedly different from ordinary buildings. Three-coat work is the best. The priming coat on the woodwork should be mostly oil, and, as far as possible, the material should be dipped into a tank of paint. Iron and steel framing material should be primed with a metallic paint. The priming coat should be applied before the material is exposed to the weather. The material of the second and finishing coat should be pure linseed oil and white lead. Experience has shown that this material is the best for this work. The color should be white or a light tint of any desired shade may be used, but no heavy color should be adopted which requires coloring matter in place of the lead in the mixing. Each coat should be applied thin and well rubbed out. While the appearance may not be quite so fine when the work is first done, the paint will not peel off, and will last longer and form a better protection for the structure than when it is put on in thick coats. It will also form a good base for repainting, and this should be done in a similar manner. It is economical to repaint a greenhouse every two years, and generally one coat will be sufficient. Neglected unpainted greenhouses soon suffer, and are also very unattractive.

Plant-tables.

Stages for plants in pots, or raised beds for planting out, usually cover the entire area of a greenhouse except the walks, and their cost constitutes a considerable proportion of the expense. Palms are usually grown in solid beds or in pots or boxes sitting on the ground. Many vegetables are grown in solid beds near the ground-level. Roses and carnations are usually in raised beds. Angle-iron frames supported on adjustable gas-pipe legs, with slate or tile bottoms, form the best plant-tables (Fig. 1758). Wood bottoms which can be readily renewed are frequently substituted, saving a part of the first cost. When the table supports are of wood, care should be taken that they are not fastened against any part of the framework of the house, unless iron brackets are used so as entirely to separate the woodwork.

Ventilation.

No greenhouse is complete without a good ventilating apparatus. About one-tenth of the roof should be arranged to open or close for ventilation, although this percentage will vary according to the form of house and the purpose for which it is used. It is not desirable to open all the ventilators in a long house with one set of apparatus, for frequently one end will not need so much ventilation as the other end or may be affected by the wind, forming a current lengthwise of the house. To avoid this, a greenhouse 200 feet long should have three or four sets of apparatus which can be operated separately. In all greenhouses of considerable width it is desirable that ventilation should be provided on both sides of the ridge so that the ventilation can be given on the "leeward" side, which will prevent the wind from blowing directly into the house.

Heating.

The success of the florist, gardener or amateur in the management of a greenhouse depends largely on the satisfactory working of the heating apparatus. There are two systems of greenhouse heating which, when the apparatus is properly installed, are economical and satisfactory; viz., hot water and steam. The open-tank hot-water heating has more advantage in its adaptation to general use than any other, and is so simple that its management is readily understood by anyone. It is practically automatic and is capable of maintaining an even temperature for ten hours without attention. Low pressure steam-heating is well adapted to large commercial ranges, and to large conservatories in parks and private places where a night attendant can be kept in charge of the fires to turn on and shut off steam from the radiating pipes as the changing outside temperature may require. The heating of greenhouses to the best advantage, under the varying conditions of climate and interior requirements, demands, like the designing of greenhouses, the services of an experienced specialist in horticultural work.

LORD & BURNHAM CO.

Vegetable forcing-houses.

The evolution of the vegetable forcing-house has been rapid and very pronounced. From the low-built, flue-heated, dark stuffy type of house to the high, well-lighted, steam- or hot-water-heated, well-ventilated house is a change that has come not only in a very short time but which has been as marked as the transition from the ox-cart to the automobile.

Location.

In selecting a suitable location for vegetable forcing-houses, one of the most important things to consider is the marketing possibilities. It would be folly to go to the expense of building a forcing-house in which to grow vegetables to make money if they could not be sold at a profit above cost of production. The most desirable markets are those within easy driving distances. If it is necessary to ship the produce to be grown, electric lines will usually be found more economical carriers than steam lines. A grower is nearly always at a disadvantage if he has but one available road to ship over. Competition insures cheaper and better service. Cities with 25,000 to 50,000 population are often more desirable markets than much larger cities. Cities which are the chief shipping-points for southern-grown vegetables are not so good markets for forcing-house products as are the cities which are not so accessible from the localities making a business of growing winter vegetables for northern markets.

Another matter of importance to consider in choosing a forcing-house site is the cost of fuel. If natural gas can be secured at a reasonable cost it is a very satisfactory fuel. Coal is used most commonly as a fuel. When calculating the cost of coal, the hauling of it from the nearest shipping-point to the forcing-house should be included. It is expensive to move large quantities of coal a long distance, especially if the road is not good. When a dirt road must be used, it is usually best to do the hauling in late summer rather than in winter.

While any productive soil can be made suitable for forcing purposes, it is easier and cheaper to prepare a sandy soil than a heavy clay soil. Other things being equal, therefore, a location where the soil is a sand or sandy loam is to be preferred to a clay soil.

As large quantities of water are used in the forcing-house, an abundant supply should be known to exist before a site is selected for the houses. It is cheaper to build and easier to operate a forcing-house on level than on sloping land. A level site should, therefore, be selected if possible.

It is also an advantage to have the houses protected on the sides from which the prevailing winds come. Trees, hills or buildings are suitable for this purpose, providing they are not near enough to shade the houses much of the time. The site should not be far from the dwelling, and the closer it is to the market or shipping-point the better. A location which cannot be satisfactorily drained or which is subject to overflow should of course be avoided.

Types of forcing-houses.

Of the various types of forcing-houses, even-span, three-quarter-span, hillside and lean-to, only two are being built very generally at present. Many New England growers prefer the three-quarter-span, while the even-span is most popular in all other sections of the country in which forcing-houses are commonly erected. The three-quarter-span is used on sloping land as much as the hillside type of house, or even more. Good results are secured with either form.

Form of construction.

All-wood houses.—In the all-wood form of construction no iron is used except in the heating-plant. The walls may be all wood, or wood and concrete. The posts may or may not be set in concrete. The all-wood house was by far the most common form of construction only a few years ago and certain growers in various parts of the country still prefer the all-wood houses. Red cedar and cypress are the kinds of wood commonly used for forcing-house erection.

Semi-iron houses.—In the semi-iron form of construction all supporting posts, purlins and braces are made of iron pipes or angle-iron. The walls are usually made of concrete and all interior posts are set in concrete. The semi-iron houses are more expensive to erect than the all-wood houses but they are more durable and most growers think they are cheaper in the end.

All-iron houses.—In the all-iron construction the entire framework is of iron. The various parts are put together in such a way that the houses are very rigid. This form of construction is the most durable of all and will stand a greater weight of snow and more severe winds than the semi-iron or all-wood houses. The first cost of the all-iron houses is from one-third to one-half greater than the semi-iron construction, and this fact alone stands in the way of the general use of this construction. In spite of this objection, a number of large all-iron houses have been erected recently and they seem to be increasing in popularity, especially in the eastern part of the United States.

Trussed houses.—In the trussed form of construction, steel truss-rods are used to take the place of a part or all of the iron or wooden posts and braces used in the other forms of construction. The trussed houses are very convenient to work in and very little shade is cast by the framework. The truss-rods are frequently made to support the heating-pipes. They are also convenient supports for the wires upon which the cucumber and tomato vines are supported. As built in the past, trussed houses have not been strong enough, in all cases, to resist the weight of heavy snows and the force of severe winds. Several such houses have been demolished. If this defect can be eliminated this type of house will be very desirable.

Special features of forcing-house construction.

Width of houses.—The width of the forcing-houses in general use varies from 12 to 150 feet. In the East the tendency is to build houses 40 to 50 feet or more in width. In most parts of the West, the preference is for houses from 12 to 40 feet wide. However, there are individual growers in most sections of the West who prefer houses over 40 feet wide. The narrower houses are cheaper to build and can be kept in repair more cheaply and easily than wide houses. The wider houses, it is thought, can be heated more economically and are better adapated to the growing of warm plants such as cucumbers and tomatoes in winter than the narrower houses.

Length of houses.—The length of forcing-houses varies from 50 to 800 feet. When the gravity system of hot-water heating is used the houses are seldom over 200 feet in length. When either steam or hot water with artificial means of circulating is used, the houses may be of any length up to 1,000 feet. In most forcing centers the length of the houses has not exceeded 500 feet.

Direction of houses.—Lean-to and hillside houses are usually built with a southern exposure. Three-quarter-span houses are generally built to run east and west with the long span to the south. Even-span houses are built to run north and south, east and west and in some cases northeast and southwest. While there is not much difference in the results secured in even-span houses run either direction, there is a better distribution of sunlight throughout the day in houses which are run north and south.

Height of gutter.—Low gutters are almost entirely a thing of the past. Modern houses are usually built with gutters at least 6 feet high and 7-feet gutters are not uncommon. The outside walls of modern houses are very largely of glass construction. Connected houses are commonly built with no dividing partition except in case of extreme width when an occasional glass partition is put in. Some of the advantages of the high gutters combined with glass in the side walls and few or no dividing partitions are: greater convenience in working, better circulation of air and less shading. The former belief that the glass must be close to the plants, for best results has been found to be erroneous.

Pitch of roof.—The roofs of most even-span forcing-houses are built with a pitch of 30° to 35°. Three-quarter-span houses are usually built with the short span of the roof steeper than the long span. Hillside and lean-to houses are sometimes built with considerable less than a 30° pitch to the roof.

Glass and glazing.—Nothing but "A" quality glass is used in modern forcing-houses. Single-strength has been almost entirely replaced by double-strength glass. The standard size is 16- by 24-inch glass. It is usually laid the narrow way, although in sections of the country in which the snowfall is light the glass is frequently laid the 24-inch way. Twenty- by 24-inch glass is used by some growers. Butted glass was popular for a time and is yet with some growers, but lapped glass is most commonly used at the present time. When lapped, the glass is imbedded in putty and secured in place by the use of glazing-points. Butted glass is held in place by grooved strips of wood placed over the edges and fastened to the sash-bars with screws.

Ventilation.—An abundance of ventilation should always be provided, as the health of the plants is governed to a considerable extent by the ventilation given or not given at the proper time. When the narrow ridge-and-furrow type of forcing-house is used, provision is made for ventilators on only one side of the roof. If the houses are 30 or more feet in width, ventilators are usually placed on both sides of the ridge. In some cases, the ventilators are continuous, but owing to the liability of binding when so built most growers use separate ventilator sash. The sash are separated from each other by one or two lines of fixed glass. They are hinged on the ridge or on the header at the lower edge of the sash. When they are hinged on the header and open at the ridge the ventilation is more free, but cold draughts of air and rain or snow are more liable to enter than when the sash are hinged at the ridge and open at the lower edge. Side ventilators are a decided advantage in warm weather. When they are not provided, the air in the houses often becomes stale and oppressive. In such a condition it is unsuitable for normal plant-growth and unpleasant for those who are obliged to inhale it. Easy-working ventilator machinery should be provided for the ventilators both on the sides and roofs.

Heating.—For small forcing-houses, hot water is undoubtedly the most satisfactory method of heating. Some of the advantages of hot water over steam heat are: No night fireman is needed in small forcing-houses as the fire can be left for several hours without attention. Less fuel is required, especially in mild weather. The proper amount of moisture in the air can be maintained more easily. The heating-pipes if kept filled with water will outlast steam-heated pipes. The chief advantage of the steam heat over hot water is that it is cheaper to install. The reason for this is that when gravity is the means of circulating the water, larger pipes are required for properly heating the houses with water than are necessary where steam is the heat used. The gravity system is the principal method used in small hot-water-heated houses. Another advantage of steam over hot water is that the heat can be regulated more easily. When steam sterilization is practised it is an advantage to be able to use the same boilers for this purpose as are used for heating the houses. While a larger part of the large ranges of houses are heated with steam, some of the largest are heated with hot water. A ten-acre range of houses near Toledo, Ohio, is heated with hot water which is pumped through 1¼-inch heating-pipes. The houses are 700 feet long and cover a width of over 600 feet. There is but one heating-plant and it is located at the center of one side of the range. The heating-pipes are close to the ground and are nearly level from one end of the houses to the other. The water is pumped through the entire length of pipes in a very few minutes. The installation of this hot-water heating-plant cost little if any more than a steam heating-plant would have cost and it can be operated more cheaply than a steam plant which would be large enough to heat a range of houses of the same size.

Heating-pipes.—Practically all pipes used for heating purposes at the present time are of wrought-iron. They are threaded and can be united by screwing them into connections made for the purpose. This method of connecting furnishes a tight joint and can be easily put together. Two-inch pipes are used as a rule for hot-water heating with gravity means of circulating. For hot water with forced circulation and for steam, 1¼-inch pipes are generally considered the best size to use.

Benches vs. beds.—In nearly all vegetable-forcing centers, except Chicago, raised benches are no longer used except by an occasional grower. The cost of building the benches is so great that most growers think the added cost more than offsets the advantages of the benches over the beds. Cement benches when arranged for sub-irrigation are very satisfactory. They are especially desirable for lettuce and tomatoes. Surface-watered benches are not nearly so satisfactory for these crops as sub-irrigated benches. Ground beds are frequently made with concrete sides but the more recent plan is to have nothing but narrow concrete walks to separate one bed from another.

Service room.—One of the features which goes with an up-to-date vegetable-forcing plant is a conveniently arranged and well-lighted service room. Provision should be made for washing vegetables and for other operations which go with a proper preparation of the vegetables for the market.

Plant-house.—Another important adjunct to a modern forcing-house is a plant-house which is independent of the other part of the range so far as the heating of it is concerned. To grow young plants successfully, especially warm plants such as cucumbers and tomatoes, it is important to be able to provide the proper temperature for each kind of plant. This can be done to best advantage if the plants can be grown in a plant-house built especially for that purpose. C. W. Waid.

Greenhouse glass.

The selection of glass for greenhouses, and the nature of the imperfections which render it undesirable for such use, are questions which have received much attention from horticultural writers, and which have brought forth a variety of answers. Three qualities are essential in all glass to be used in greenhouse construction: first, minimum of obstruction to solar rays; second, strength sufficient to withstand the strain of winds and storms, especially hail; and third, freedom from defects that render it liable to burn plants grown under it.

1759. Burned areas on a begonia leaf.

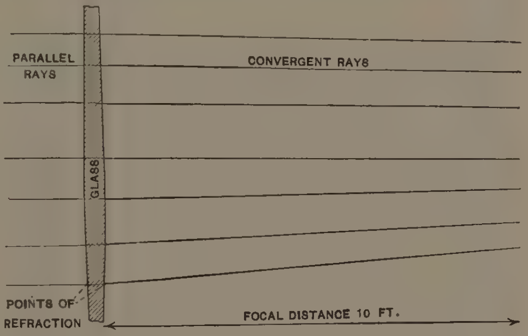
It is an established fact that plants thrive best under a clear and transparent glass, which lets through the greatest possible percentage of the sun's rays. This includes all the solar rays, calorific or heat rays, and actinic or chemical rays, as well as the colorific or light rays. Clear white glass of the grade known as "single thick" (twelve panes to the inch) lets through from 60 to 70 per cent of the sun's rays; common green glass of the same thickness, 52 to 56 per cent, and "double thick" (eight panes to the inch) common green glass, from 50 to 52 per cent. This percentage is reduced by other colors, dark blue glass letting through but 18 per cent. In connection with the matter of tint, it should be noted that some glass, especially clear white glass purified with arsenic acid, or that in which a large amount of potash is used in proportion to the amount of lime employed in manufacture, becomes dull after long exposure to the weather, the dullness being occasioned by the efflorescence of salts contained in the glass. Before this disintegration has proceeded too far, the crust or efflorescence may be removed with muriatic acid.

The strength of glass depends upon its thickness and upon the thoroughness of the annealing. Glass is annealed by passing through a series of ovens, where it is raised to a high heat and then gradually cooled; whatever toughness and elasticity the finished product may contain is due to this process. The thickness of glass varies, not only with grades (single and double thick), but also more or less within the grades, and even in different parts of the same pane. Single thick glass is too thin for use in greenhouses; in selecting any glass for such a purpose it should be examined pane by pane, and all showing marked variation in thickness, either between panes or in different parts of the pane, rejected. A pane of varying thickness is much more liable to breakage from climatic changes or sudden shocks than one which is uniform in this regard. From the foregoing statements it will be seen that, in general, the ordinary double-thick green glass is best as regards both tint and strength, green glass being less liable to change in tint than white, and the double-thick being the stronger grade. By green glass is meant simply the ordinary sheet glass, the green color of which is noticeable only at the cut edge.

It has long been a common opinion that such visible defects in sheet glass as the so-called "bubbles," "blisters," and "stones," produce a focusing of the solar rays passing through them, thus burning the foliage of plants grown under glass containing these defects (Fig. 1759). This view has been held by glass manufacturers and horticulturists alike, and seems not to have been contradicted publicly until 1895 (Bulletin No. 95, Cornell University Agricultural Experiment Station, page 278). In view of the erroneousness of this theory, it is rather remarkable that it should have gained such prevalence. Nearly all bubbles and blisters are thinner in the middle than at the periphery, being thus concave rather than convex lenses, and actually diffusing the rays of light passing through them rather than producing destructive foci. While it is true that sand-stones or knots in glass may produce foci, these points of focus scarcely ever exist more than a few inches from the surface of the glass; consequently, these defects can do no damage when occurring in roofs several feet distant from the growing plants below.

The only full and complete series of experiments on this subject in this country (conducted at the Cornell University Agricultural Experiment Station, the Physical Laboratory of Cornell University, and a glass factory in Ithaca, New York, but yet unpublished) shows the true cause of the burning by glass to be the variation in thickness of the entire pane, or a portion of it, thus producing a prismatic or lens-like effect (Fig. 1760), which causes a more or less distinct focusing of the sun's rays at distances varying from 5 or 6 feet to 30 feet, or even more, from the glass.

This defect usually occurs along the side or end of the pane and is not visible to the eye, but it may be detected easily by using the micrometer caliper or by testing in the sunlight. It may be found in all kinds of glass, and is caused by the glass-blower while reducing the upper or pipe end of the cylinder from which sheet glass is made, thus facilitating the removal of the "cap" or neck end of the cylinder, by which it is attached to the pipe while being blown. The defect, as already stated, is one which may be found in all grades and qualities of sheet glass, of both foreign and domestic manufacture. The fact is well known that differences in the thickness of spectacle lenses, which are imperceptible to the eye, may produce sufficient refraction to vary materially the direction of rays of light passing through such lenses, and it is not difficult to see that the same effect may be produced by similarly imperceptible variations in the thickness of sheet glass. That this is the case has been conclusively shown by the series of experiments mentioned above. These also show that burns on plants caused by defective glass roofs occur in lines and not in isolated spots, burns of the latter description being usually the result of a weakening or deterioration of tissue, due to carelessness in the matter of ventilation, humidity of the atmosphere, water, and temperature of greenhouses, rather than to defects in the glass.



1760. Refraction of light rays by an irregular pane of glass.

If, therefore, it is not possible to secure glass of uniform thickness with certainty, it may be found cheaper and often fully as satisfactory to purchase the lower or common grades of double-thick glass, using in the roof only those panes which show, after testing in the sunlight for foci, an entire lack of the prismatic character which makes them dangerous to plants grown under them.

J. C. Blair.

Greenhouse heating.

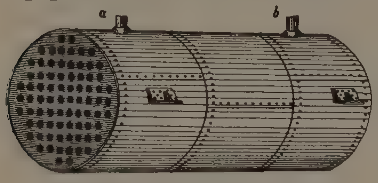
In all sections in which the temperature drops below the freezing point, it is necessary to provide some artificial means for heating greenhouses. Nearly all modern structures are warmed either by steam or hot water, although hot-air flues are occasionally used. While hot water is preferred for small ranges of glass, as it can be depended upon to furnish an even degree of heat when left for a number of hours, steam is very generally used for extensive plants, as the cost of piping the houses is much less than when hot water is used. Steam boilers require more attention than hot-water heaters, but when there is more than 10,000 or 12,000 square feet of glass, it is best to have a night fireman and watchman, and the extra expense can be made up by the saving in the cost of fuel, as it will be possible to use a lower grade of coal. Under these conditions the cost of running a steam plant will be as low as with hot water, but in small houses, where hard coal is used, and the fires receive no attention for six to eight hours during the night, hot-water heaters will be cheapest to operate, and will be most satisfactory. Some of the up-to-date ranges of the largest size make use of hot water and are able to secure a perfect circulation by the use of steam or electric pumps, which also make it possible to reduce the size of the piping, and as a higher temperature is maintained in the water, the amount of radiation required and consequently the cost of piping the houses is reduced practically to that in steam systems. Similar results can be secured in closed systems where some method of placing the water under pressure is used. See, also, under *Forcing-houses*, p. 1402.

As the various flowers and vegetables grown under glass require different temperatures, the piping of greenhouses has to be varied accordingly. Thus, although it may vary from 3° to 5° for different varieties of the same species, our common plants require the following night temperatures: violets and lettuce, 45° to 55°; radishes and carnations, 50° to 55°; roses and tomatoes, 60° to 63°; cucumbers and stove plants, 70°.

Boilers.

For small ranges, whether steam or hot water is used for heating, the best boilers are those constructed of cast-iron as they will be found more durable than those in which wrought-iron or steel is used. By using either vertical or horizontal sections, it is possible to build up boilers of considerable size, but, especially if to be used for steam heating, it will be preferable to use wrought-iron or steel boilers if they have a capacity of more than 2,000 square feet of radiation. Except for those of extremely large size, the ordinary tubular boilers will be found adapted both for steam and hot-water heating, although when used for hot water they will be more effectual if the entire shell is filled with tubes, as there is no occasion for leaving a steam space at the top of the boiler. Such boilers are of low cost, economical and durable.

There are also on the market several forms of wrought tubular boilers which are giving good results for heating greenhouses with hot water. For ranges of the largest size, where forced draft is used, water-tube boilers are extremely powerful and very satisfactory. When installing a heating-plant, it will be safest to use two or more boilers rather than one large one of the same capacity, as when there is only a single boiler serious losses may result if repairs to the boiler become necessary in extremely cold weather, which might be lessened or entirely prevented when there are two or more boilers in the battery, and it is possible to cut out the one which has become damaged. Especially in mild weather during the spring and fall, the firing will be more economical when it is possible to use a boiler just large enough to heat the houses, rather than one which is several times larger than is necessary at that time, as would be the case when only one boiler is used.



1761. Horizontal tubular boiler for hot water.

The durability of the boiler and the economy of heating will be greatly increased when the heating capacity is considerably larger than is really necessary, as when the firing is forced in extremely cold weather it will not only result in a loss both in fuel and labor, but will shorten the life of the boiler.

The size of hot-water boilers is usually expressed in terms of radiation, or the number of square feet of heating surface it can supply economically. In a given boiler there is a fixed ratio between the size of the grate and the area of the fire surface of the boiler, but this will depend very largely upon its construction and efficiency of the fire surface, as well as upon the size of the boiler. In the case of small hot-water boilers the ratio between the grate and fire surface is often as small as 1 to 15, while it may be as much as 1 to 35 in larger ones, and even more when the boilers have frequent attention and hard coal is used. One reason for using a relatively large grate in small boilers is because it makes it possible to leave the fire for eight or ten hours without care or attention, while for large boilers and where a night fireman is employed, the ratio between the grate and fire surface may be much greater.

The capacity of steam boilers is usually rated in horse-power, and it is considered that for each horse-power a boiler will heat 100 square feet of radiation; an average of 15 square feet of fire surface is considered equal to one horse-power, it being customary to estimate that 10 or 12 feet in a large boiler will equal one horse-power, while in a very small one as much as 18 feet would be required. Thus, in medium-sized boilers an area of 10 square feet of grate will answer for 250 square feet of fire surface and this will be sufficient for about 1,700 square feet of radiating surface when steam is used; and as 75 to 100 per cent more radiation will be required when hot water is used, a boiler of the above size will answer for 2,800 to 3,400 square feet of hot-water radiation. In the case of small boilers that will not have attention at night, it is usually advisable to reduce the above estimates about 25 per cent, and when a boiler is required for 1,000 square feet of radiation, we should select one that is rated at 1,250 square feet.

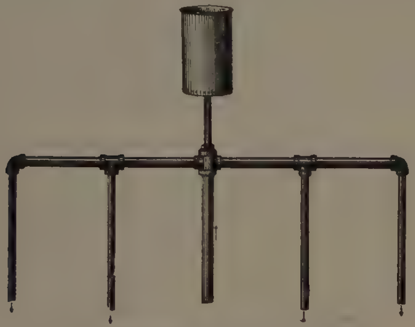
Home-made coil boilers are sometimes constructed for hot-water heating since the cost will generally be considerably less than for tubular boilers. As a rule, however, they will be found less durable and lacking in efficiency as compared with the better class of greenhouse boilers now on the market. For making such boilers, 2-inch wrought-iron pipe in lengths of 4 to 6 feet is used. Formerly 1-inch pipe was used for coil boilers but it is comparatively thin, and, especially where the threads were exposed it was quickly eaten through so that it proved far from being as durable as the larger sizes of pipe. There was also more trouble from the boiling over of the water than when larger pipes were used and if the boilers are constructed of 1-inch pipe it is necessary either to have an elevated expansion tank or run it as a closed system. In making a coil boiler, the pipes are cut of the desired length and the ends are connected either by return bends or by manifolds so as to form a number of vertical coils, each containing from six to ten pipes. The upper ends of the manifolds are joined at the front end of the heater and connected with the main flow-pipe; while the lower ends of the rear manifolds are joined to the returns. As a rule, the grate is of the same width as the coils and from one-half to two-thirds as long.

Although a box coil is much cheaper than a cast-iron heater, when we have added the cost of the grate, doors and other fittings, and of bricking it in, the amount saved will not be large, and its use will often be found less economical, especially as the coil boilers are, as a rule, not more than one-half as lasting as cast-iron boilers, most of which are complete in themselves and require no brickwork or trimmings.

Hot-water piping.

When hot water first came into use for the heating of greenhouses, 4-inch cast-iron pipes were used, but, as the joints were packed with oakum, cement or iron filings, they frequently gave trouble by leaking and it was much more difficult to make changes or repairs than in the present systems for which small, wrought-iron pipes with screw joints are used. Owing to the large amount of water in the cast-iron pipes, the circulation was necessarily quite sluggish and it was not easy to secure the high temperature in the water that can be obtained with smaller pipes. Another objection to the use of these large pipes is that it is not possible to carry the flows overhead, while with smaller pipes one may not only have the flows but some or all of the return-pipes above the level of the benches. By elevating the pipes above the level of the boiler, the rapidity of the circulation and the temperature of the water in the pipes can be considerably increased.

In case a number of houses are to be supplied from one boiler, or if the heater is at some distance from the coils, it is better to start from the boiler with one large flow-pipe, or with two pipes leading from different sides of the boiler, rather than carry an independent pipe to each house. When there are several houses to be heated, it is customary to have them side by side and one large flow-pipe can then be run across the nearest end of the houses from the boiler. If the houses run north and south, the boiler may be located at one corner or in the middle of the north end of the range, and either a work- or storeroom, or some other form of a head house, should be constructed in which the main heating-pipes can be carried, as well as to protect the north end of the houses and facilitate getting from one to another. Sometimes greenhouses run east and west, in which case there should either be a head house at the east end of the range, or if the houses are more than 200 feet in length it may be run through the center of the houses.



1762. Supply-pipe for under-bench flows.

The size of the main feed-pipe as well as of the branch pipes should be in proportion to the amount of radiation they supply. In determining the amount that can be handled by pipes of different sizes, it is always advisable to use somewhat larger supply-pipes when all of the radiation, both flow and return, are under the benches, than when all of the flow-pipes, at least, are overhead. A similar allowance should be made when the boiler is partly above the level of the returns, as compared with systems in which the coils are a number of feet above the top of the boiler, since in the latter case a much smaller supply-pipe will suffice. In a general way, the following sizes can be used as supply-pipes:

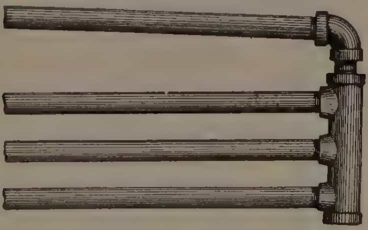
Size of pipe.	Square feet of radiation.
1½-inch	75 to 100
2 -inch	150 to 200
2½-inch	250 to 350
3 -inch	400 to 600
3½-inch	600 to 800
4 -inch	1,000 to 1,200
5 -inch	1,500 to 2,000
6 -inch	2,500 to 3,500

The main supply-pipe or pipes should, if possible, rise vertically from the heater to a point somewhat higher than the highest point in the system, and then as it runs out through the houses should be given a slight fall, say 1 inch in 20 feet, so that there will be no opportunity for the pocketing of air in the pipe. While a slight downward slope will unquestionably give better results than the uphill arrangement which is sometimes used, the difference will be comparatively slight and, if the circumstances make it preferable to run the flow-pipes uphill, satisfactory results will be obtained provided they are considerably elevated above the boiler. Especially, if the flow-pipes run uphill, it will be advisable to have them of good size.

When taking off the supply for each of the houses, one large pipe of a size sufficient to provide the amount needed may be used, or from two to five smaller pipes may lead from the main flow-pipe into each of the houses. For houses up to 250 feet in length, it will generally be found desirable to run 2½-inch flow-pipes through the house, but for longer houses 3-inch flow-pipes should be used. Just how many flow-pipes will be needed will depend not only upon the length of the house, but upon the number of return-pipes to be supplied. Thus, while a 2½-inch flow will supply two 2-inch returns in a house 250 feet long, the number of returns which it will feed in shorter houses will be nearly in inverse proportion to the length of the return coils. When the amount of radiation to be supplied does not exceed 250 to 350 square feet, one 2½-inch flow-pipe in a greenhouse will be sufficient and this should preferably be placed from 1 to 3 feet below the ridge. For slightly larger houses, two flow-pipes may be located on the wall plates. If as many as five pipes are necessary, the fourth and fifth pipe may be suspended from the roof under the middle of the sash-bars. In the case of houses so large that more than five 2½-inch flow-pipes are required, 3-inch flows should be used.

The length of the coils and their height above the boiler will determine the size of the pipe which should be used for the returns, since a smaller size will answer in short coils and in those that are considerably elevated than for long coils which are but little, if any, above the level of the boiler. For the construction of coils 75 feet or more in length, 2-inch pipe should be used, and it will generally be found preferable to a smaller-sized return-pipe when they are only 50 feet in length, especially if the flows are under the benches or when the coils are below the top of the boiler. For short coils, pipes as small as 1¼-inch may be used where they are somewhat elevated but for ordinary commercial greenhouses it will be better to use 2-inch pipe for the returns, although 1½-inch pipe might answer in houses up to 75 feet in length, as, while small pipe furnishes the most effective radiation to the square foot, the increased friction impedes the circulation.

In narrow houses, the return-pipes may be placed upon the side walls, but as the width increases it will be generally advisable to have from one-third to one-half of the returns either under the benches or in the walks when beds are used. From the fact that running the pipes overhead will not only improve the circulation but will prevent cold draughts of air upon the plants, it is often desirable when but one overhead flow-pipe is used to bring back one return upon each of the purlins. When the end of the house is much exposed, it is an excellent plan to drop down one feed-pipe from the end of the main, or two when there is a door in the end of the house, and supply coils running in either direction to the corner of the house and thence along the walls toward the end where the heater is located. Particularly when the pipes are but little, if any, above the top of the boiler, the circulation will be improved by carrying the return-pipes as high as possible, but of course care should be taken when they are under the benches not to have them so high that they will dry out the soil.

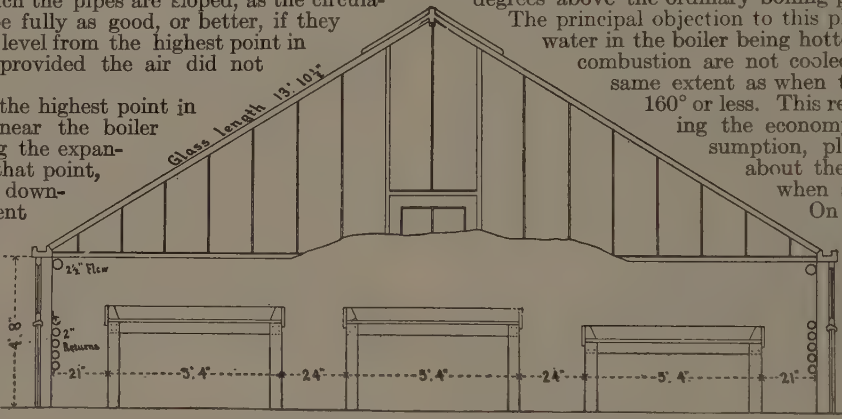


1763. Pipe work for modern greenhouse heating. A wall coil.

The returns may be arranged in horizontal coils under the benches, or in vertical coils on the walls, or on the sides and supports of the beds and benches. The pipes in the coils may be connected at their ends either by means of manifolds, or by tees and close nipples, but in either case provision should be made for expansion of the pipe which with vertical wall coils may be done by running them partly across the ends of the houses and the same means may be used in horizontal coils, or the headers at the lower ends of the coils may be connected with the ends of the pipes by means of nipples and right and left ells. Whenever possible, there should be at least two returns supplied by each of the flow-pipes and the number may be increased until the capacity of the flow is reached. In determining just how many returns may be supplied by a given flow-pipe, one should always make allowance for the radiation furnished by the flow-pipe itself and, as the friction will be greater in a large number of short returns than for the same radiation with long returns, this should be considered in adjusting the ratio between the flow- and return-pipes.

Even greater attention should be given to the grading of the small return-pipes than to the larger flow-pipes, as the danger from pocketing of the air will be increased. For the smaller sizes, it will be advisable to give them a slope of at least 1 inch in 15 feet; but, if carefully graded and securely supported at intervals of 10 feet, good results can be obtained with 2-inch pipe with a fall of 1 inch in 20 feet; and if no more than 1 inch in 30 feet is available even this light fall will generally suffice to rid the pipes of air. This is really the main object for which the pipes are sloped, as the circulation would be fully as good, or better, if they are run on a level from the highest point in the system, provided the air did not pocket.

By having the highest point in the system near the boiler and attaching the expansion-tank at that point, one secures a downhill arrangement of the pipes which not only gives a better circulation than when the flow-pipes run uphill, but it does away entirely with air-valves which must be provided when the flow-pipe runs uphill and which often give trouble.



1764. Carnation-house, 100 x 23 ft. 6 in., piped for hot water.

The method of piping which has been advocated, i.e. running one or more pipes in each house to the farther end and there connecting them with the returns, will give a more even temperature than can be secured in any other way. Formerly, it was the custom to connect the supply-pipes with the coils at the end of the house nearest the boiler. In some cases, one-half of the pipes in the coils served as flows to feed an equal number of return-pipes, or all of the pipes in the coil were connected at the farther end of the house with a main return-pipe, of the same size as the feed-pipe, which was brought back underneath the coil, or all of the coils in the house were connected into one main return. When the latter arrangement is used, the heating of the house is less uniform than with an overhead flow-pipe, the farther end of the house being cooler than the one near the heater.

Unless the heating system is connected directly with the water-supply system, which is used as an expansion-tank, a special tank must be provided and connected with the highest part of the flow-pipe or with one of the returns near the heater. While it would answer if this tank is located at some point but slightly above the heating system, it is always desirable to have it somewhat elevated, as this will raise the boiling-point of the water in the system and hence increase its efficiency, as well as lessening the danger of its boiling over. The pipe connecting the expansion-tank with the heating-pipes should not be less than ¾inch and this should be increased to 1½ to 2 inches in large systems. The size of the expansion-tank should be sufficient to equal the amount which the water in the system will increase in volume when it is raised from a temperature of 40° to 200°, with a margin of perhaps 50 per cent. By connecting the expansion-tank with the highest part of the system, one not only does away with the necessity of using air-valves but also lessens the tendency of the water to boil over.

When there are several houses in the range connected with one system, it is always a good practice to have a valve upon the supply-pipe leading to each house, with other valves upon at least one-half of the coils. It will thus be possible to reduce the radiation in each house or to cut it out entirely if desired.

Hot water under pressure.

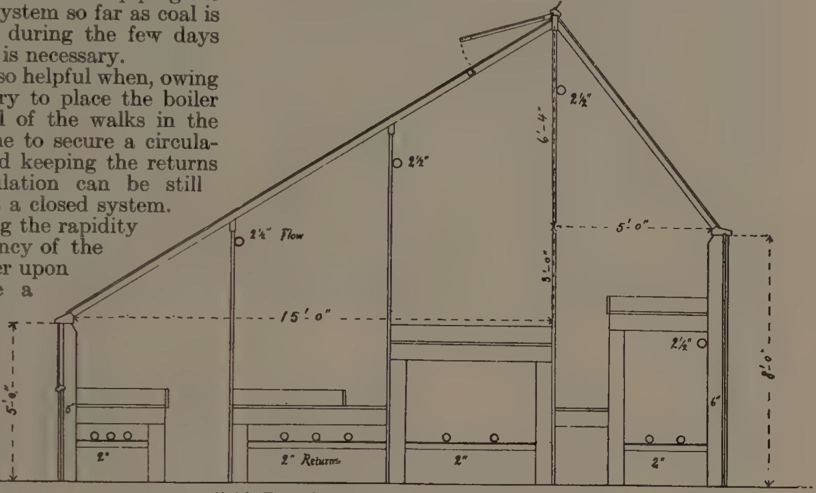
Especially in large ranges it is now becoming customary to place the water under pressure, thus making it possible to raise the temperature at which it will boil, and in this way the circulation can be improved, and instead of the water in the returns having an average temperature of 150°, it can be maintained several degrees above the ordinary boiling-point of water. The principal objection to this plan is that the water in the boiler being hotter, the gases of combustion are not cooled down to the same extent as when the water is at 160° or less. This results in lessening the economy of coal-consumption, placing it upon about the same plane as when steam is used. On the other hand, this system has the merit of reducing the amount of radiation required in the heating-system, and in this way lessening the cost of piping the greenhouse fully twenty-five per cent.

Various methods of placing the water in the heating-system under pressure have been employed. Among them is to use a safety-valve and a vacuum-valve, either upon the expansion-tank, or if this is not closed, upon the expansion-pipe within the tank. The safety-valve allows either the air or the water, as the case may be, to pass out of the system when the pressure desired is reached, while the vacuum-valve permits the air or water to re-enter the system when the pressure drops

What is known as the "mercury generator" or "circulator" also serves the same purpose. In these a column of mercury prevents the escape of the water in the system until the pressure has reached the point desired, when it allows a portion of the water to escape and, later on, to re-enter the system when the pressure decreases. It will be seen that this acts in exactly the same way as the safety-valve and vacuum-valve described above. By raising the boiling-point of water and improving the circulation, it not only makes it possible to use smaller pipes both for flows and returns, but the amount of radiation required will be considerably reduced. In fact, although it is not advisable to carry it to that extent, it is possible to reduce the amount of radiation practically to that required for steam-heating.

This system is of value particularly in sections of the country in which the usual winter temperature is well above zero but where the mercury drops 10° to 15° for a short period each winter. By piping the houses so that the desired temperature can be obtained for the houses in ordinary weather by using an open system, it will then be possible by using a "circulator" to maintain the same temperature in the houses even though the mercury drops 15° or 20° lower. This will make a considerable difference in the cost of piping the houses and the efficiency of the system so far as coal is concerned will be affected only during the few days when the use of the "circulator" is necessary.

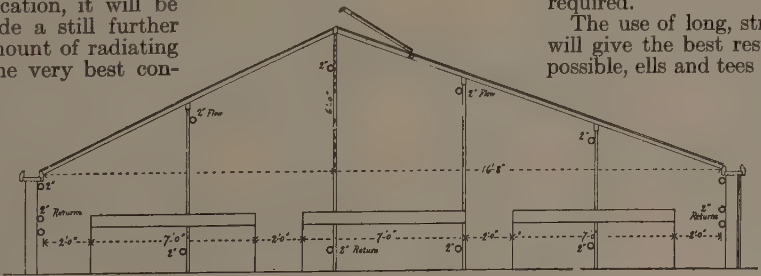
The use of a closed system is also helpful when, owing to local conditions, it is necessary to place the boiler upon or slightly below the level of the walks in the houses. While much can be done to secure a circulation by using overhead flows and keeping the returns as high as possible, the circulation can be still further improved if it is run as a closed system. Still another method of increasing the rapidity of the circulation and the efficiency of the heating-system is to place either upon the main flow- or return-pipe a pump, worked by steam or electricity, by which it will be possible greatly to accelerate the circulation of the water, so that such matters as the relative elevation of the boiler and heating-pipes will need but little consideration and it will be possible to decrease to a considerable extent the size and number of the heating-pipes.



1765. Rose-house, 150 x 20 ft., piped for water.

Estimating hot-water radiation.

Owing to the great variations in temperature and the differences in the construction of greenhouses, and also in their exposures, it is impossible to give any explicit rules regarding the amount of radiation that will be required under all conditions; but experience has shown that in well-built houses any desired temperature can be secured. Knowing the minimum outside temperature and the temperature to be maintained within the house, it is necessary only to install a heating-plant with a radiating surface having a certain definite ratio to the amount of exposed glass and wall surface. It is, of course, understood that there must be a proper adjustment between the size of the boiler and the radiating surface and that the system is so arranged as to give good results. Thus, when a temperature of 40° is desired in sections in which the mercury does not drop below zero, it will be possible to maintain it when 1 square foot of radiating surface is provided for each 5 square feet of glass; if 45° is required there should be 1 foot of radiation for 4½ feet of glass. Under the same conditions, 50°, 55°, 60°, 65° and 70° can be obtained, respectively, by using 1 square foot of radiating surface for each 4, 3½, 3, 2½, and 2 square feet of glass. When the outside temperatures are slightly under or above zero, there should be a proportionate increase or decrease in the amount of pipe used; and, if the houses are poorly constructed or in an exposed location, it will be desirable to provide a still further increase in the amount of radiating surface. Under the very best conditions, the temperatures mentioned can be obtained with a slightly smaller amount of radiation, but the greatest economy so far as coal-consumption and labor are concerned will be secured when the amount of radiation recommended is used.



1766. Violet-house with hot-water heating.

In determining the amount of exposed glass surface, the number of square feet in the roofs, ends and sides of the houses should be added, and to this it will be well to add one-fifth of the exposed wooden, concrete or brick wall surfaces. If the amount thus obtained is divided by the number which expresses the ratio between the area of glass and the amount of radiation which will be required, it will give the number of square feet of heating-pipe which must be installed. The unit of measurement of wrought pipe is its interior diameter, while its radiating surface is determined by its outside circumference, and, although it will vary slightly according to the thickness of the pipe, it is customary to estimate that 1-inch pipe will afford about .344 square feet of radiating surface to the linear foot, while 1¼-, 1½-, 2-, 2½-, and 3-inch pipe will furnish respectively .434, .497, .621, .759 and .916 square feet of radiation for each foot in length of pipe. The following example will perhaps aid in determining the amount of radiating surface and its arrangement in a greenhouse. If a house is 32 feet in width and 200 feet in length, with 30 inches of glass in each side wall and with one end only of exposed glass, and a concrete wall 3 feet high on two sides and one end, there will be about 9,000 square feet of glass. To heat this to 50° in zero weather it will be necessary to use one-fourth as much radiating surface, or 2,250 square feet. In a house of this length it will be possible to supply this amount of radiation by means of five 2½-inch flow-pipes, and the remaining radiation will be provided by means of ten 2-inch returns which will allow two for each of the flow-pipes. These figures are intended to apply when an open system is used but, if a "generator" is attached, not to exceed four flows and eight returns will be required.

The use of long, straight runs of pipe will give the best results and, whenever possible, ells and tees should be avoided, but if they must be employed special hot-water fittings should be secured.

In conservatories with high side walls it is desirable to place the flow-pipes at the plate and the returns on the walls or under the tables. Figs. 1764–1766 illustrate the lay-out of pipes in carnation-, rose-, and violet-houses.

Heating by flues.

When fuel is cheap, and when either a low temperature is desired in the house, or the outside temperature does not drop much below the freezing point, hot-air flues may be used but, while the cost of constructing them is small, the danger of fire is so great that they are often found to be far from economical. A brick furnace is built at one end of the house and from this a 10- or 12-inch flue is constructed to carry the smoke and hot gases through the house to the chimney which may be either at the farther end of the house or directly over the furnace, the flue, in the latter case, making a complete circuit of the house. When the houses to be heated are more than 60 feet long, it is advisable to have a furnace in each end, with the flue from each extending only to the center of the house and returning to the end from which it started. For the first 30 feet the lining of the flue, at least, should be of fire-brick, but beyond that the flue may be constructed of sewer-pipe.

Piping for steam.

Except that it is possible to use smaller flow- and return-pipes, the arrangement of the piping for steam-heating is not very unlike that described for hot water. Unless the houses are more than 30 feet wide and 150 feet in length, only one flow-pipe need be used and that can be carried from 2 to 4 feet below the ridge. In wider and longer houses, it is generally advisable to put in two or more flows. One of these flows can be carried on each wall-plate and in extremely wide houses others may be under the ridge and purlins.

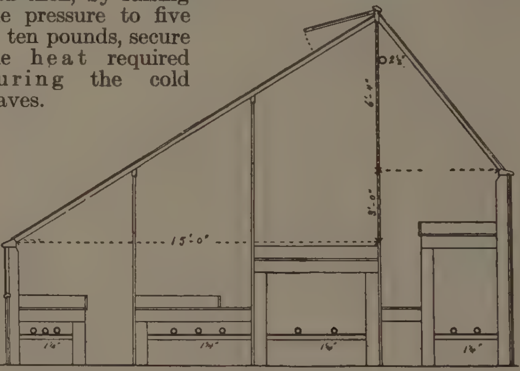
For determining the size of steam mains, a good rule to use is to take one-tenth the square root of the radiation to be supplied and consider this to be the diameter in inches of the main required. Thus for supplying 400 square feet of radiating surface we would take one-tenth the square root of 400 ($\sqrt{400} \div 10 = 2$), which will give 2 inches as the diameter of the main required. As the amount of radiation increases, a slight reduction can be made in the size of the mains and 2½-, 3-, 3½-, and 4-inch supply-pipes will answer respectively for 700, 1,000, 1,400 and 1,900 square feet of radiation. This is intended to apply with low-pressure steam, and as the steam-pressure is increased above five pounds a slight decrease in the size of the mains would be permissible.

The size of the pipes to be used for the coils will also depend upon the length of the house. For ordinary lengths 1¼-inch pipe will be desirable, but, when they are more than 250 feet in length, 1½-inch pipe may be used with low pressure steam and, in those much less than 100 feet, 1-inch pipe will answer. The location and arrangements of the coils will necessarily be determined by the openings in the walls and whether beds or raised benches are used. One of the simplest and most satisfactory ways of piping a greenhouse of moderate size, say from 20 to 30 feet in width and up to 150 feet in length, is to run the flow-pipe, which would be either 2- or 2½-inch, overhead and bring back the coils on the walls, or, if raised benches are used and crops for which bottom heat will be helpful are to be grown, from one-third to one-half of the return-pipes may be distributed under the benches and the remainder may be on the walls. The return-coils should of course be given a slight slope toward the boiler, care being taken that no opportunity is afforded for the air to pocket and prevent the free flow of the water from the condensed steam back toward the boiler. A fall of 1 inch in 10 feet will suffice, and even less will answer if care is taken in grading and supporting the pipes.

In order to prevent the water from backing up in the coils, it is desirable that they should be at least 18 or 20 inches above the level of the water in the boiler, while 3 or 4 feet would be even better and will be necessary in large ranges. Unless this can be secured it will not be possible to return the water of condensation to the boiler by gravity and either a steam trap or pump should be provided for the purpose. By means of these, the water can be carried to a water feed-tank from which it can be fed into the boilers.

There should be an automatic air-valve at the end of each coil and, in order to regulate the amount of steam, a shut-off valve should be placed upon both flow- and return-pipes leading to each house. Unless there are several coils in each house, one or more of which could be cut off by means of valves, it will always be well to have valves upon a number of the pipes in the coils so that all but one or two can be cut off if desired. To prevent the water from being forced out from the boiler when the steam is turned into the houses, there should be a check valve in the main return-pipe near the boiler.

The amount of radiation which will be required to secure a given temperature will vary to some extent with the amount of pressure carried in the boiler, or in the coils, when a reducing-valve is used, but as a rule, this is not much more than five pounds and often it is even less. It will be best to provide a sufficient amount of radiation to furnish the temperature desired in ordinary cold weather without carrying any pressure and then, by raising the pressure to five to ten pounds, secure the heat required during the cold waves.



1767. Rose-house, 150 x 20 feet, piped for steam.

In determining the amount of radiation for a steam-heated house, for zero weather, it will answer if one considers that 1 square foot of pipe will heat 9 square feet of glass when 40° are desired, and will suffice for 7, 5 and 3 where 50°, 60°, and 70°, respectively, are, required. Fig. 1767 illustrates the piping required for heating a rose-house with steam.

L. R. Taft.

Greenhouse management.

Persons usually learn to grow plants under glass by rule of thumb. Such practical knowledge is always essential, but better and quicker results are secured if underlying truths or principles are learned at the same time. Even if no better results in plant-growing were to be attained, the learning of principles could never do harm, and it adds immensely to the intellectual satisfaction in the work. There is no American writing that essays to expound the principles of greenhouse management, although there are manuals giving direct advice for the growing of different classes of plants. There are two kinds of principles to apprehend in greenhouse management,—those relating to the management of the plants themselves, and those dealing primarily with the management of the house.

The first principle to be apprehended in the growing of plants under glass is this: *Each plant has its own season of bloom.* Every good gardener knows the times and seasons of his plants as he knows his alphabet, without knowing that he knows. Yet there are many failures because of lack of this knowledge, particularly among amateurs. The housewife is always asking how to make her wax-plant bloom, without knowing that it would bloom if she would let it alone in winter and let it grow in spring and summer. What we try to accomplish by means of fertilizers, forcing and other special practices may often be accomplished almost without effort if we know the natural season of the plant. Nearly all greenhouse plants are grown on this principle. We give them conditions as nearly normal to them as possible. We endeavor to accommodate our conditions to the plant, not our plant to the conditions. Some plants may be forced to bloom in abnormal seasons, as roses, carnations, lilies (see *Forcing*). But these forcing plants are few compared with the whole number of greenhouse species. The season of normal activity is the key to the whole problem of growing plants under glass; yet many a young man has served an apprenticeship, or has taken a course in an agricultural college, without learning this principle.

The second principle is like unto the first: *Most plants demand a particular season of inactivity or rest.* It is not rest in the sense of recuperation, but it is the habit or nature of the plant. For ages, most plants have been forced to cease their activities because of cold or dry. These habits are so fixed that they must be recognized when the plants are grown under glass. Some plants have no such definite seasons, and will grow more or less continuously, but these are the exceptions. Others may rest at almost any time of the year; but most plants have a definite season, and this season must be learned. In general, experience is the only guide as to whether a plant needs rest; but bulbs and tubers and thick rhizomes always signify that the plant was obliged, in its native haunts, to carry itself over an unpropitious season, and that a rest is very necessary, if not absolutely essential, under domestication. Instinctively, we let bulbous plants rest. They usually rest in our winter and bloom in our spring and summer, but some of them—of which some of the Cape bulbs, as nerines, are examples—rest in our summer and bloom in autumn.

The third principle from the plant side is this: *The greater part of the growth should be made before the plant is expected to bloom.* It is natural for a plant first to grow: then it blooms and makes its fruit. In the greater number of cases, these two great functions do not proceed simultaneously, at least not to their full degree. This principle is admirably illustrated in woody plants. The gardener always impresses on the apprentice the necessity of securing "well-ripened wood" of azaleas, camellias, and the like, if he would have good flowers. That is, the plant should have completed one cycle of its life before it begins another. From immature and sappy wood only poor bloom may be expected. This is true to a degree even in herbaceous plants. The vegetative stage or cycle may be made shorter or longer by smaller or larger pots, but the stage of rapid growth must be well passed before the best bloom is wanted. Fertilizer applied then will go to the production of flowers; but before that time it will make largely for the production of leaf and wood. The stronger and better the plant in its vegetative stage, according to its size, the more satisfactory it should be in its blooming stage.

Closely like the last principle is the experience that *checking growth, so long as the plant remains healthy, induces fruitfulness or floriferousness.* If the gardener continues to shift his plants into larger pots, he should not expect the best results in bloom. He shifts from pot to pot until the plant reaches the desired size; then he allows the roots to be confined, and the plant is set into bloom. Over-potting is a serious evil. When the blooming habit is once begun, he may apply liquid manure or other fertilizer if the plant needs it. The rose-grower or the cucumber-grower wants a shallow bench, that the plants may not run too much to vine.

A carnation-grower writes that there is "little difference in the yearly average as to quality or quantity of flowers, but plants grown on shallow benches come into flower more quickly in the fall. Those grown in solid beds produce an abundance of flowers later in the season. The preference of commercial carnation-growers is for raised benches so that there may be more blooms early in the fall and at the Christmas holidays."

The natural habitat of the plant is significant to the cultivator; it gives a suggestion of the treatment under which the plant will be likely to thrive. Unconsciously the plant-grower strives to imitate what he conceives to be the conditions, as to temperature, moisture and sunlight, under which the species grows in the wild. We have our tropical, temperate and cool houses. Yet, it must be remembered that the mere geography of a plant's native place does not always indicate what the precise nature of that place is. The plant in question may grow in some unusual site or exposure in its native wilds. In a general way, we expect that a plant coming from the Amazon needs a hothouse; but the details of altitude, exposure, moisture and sunlight must be learned by experience. Again, it is to be said that plants do not always grow where they would, but where they must. Many plants that inhabit swamps thrive well on dry lands.

Yet, the habitat and the zone give the hint: with this beginning, the grower may work out the proper treatment. Examples are many in which cultivators have slavishly followed the suggestion given by a plant's nativity, only to meet with partial failure. Because the dipladenia is Brazilian, it is usually supposed that it needs a hothouse, but it gives best results in a coolhouse. Persons often make a similar mistake in growing the pepino warm, because it is Central and South American. Ixia is commonly regarded in the North as only a glasshouse subject because it is a Cape bulb, yet it thrives in the open in parts of New England, when well covered in winter.

The best method of propagation is to be determined for each species; but, as a rule, quicker results and stockier plants are secured from cuttings than from seeds. Of necessity, most greenhouse plants are grown from cuttings. In most cases, the best material for cuttings is the nearly ripe wood. In woody plants, as camellias and others, the cutting material often may be completely woody. In herbaceous plants, the proper material is stems which have begun to harden. Now and then better results are secured from seeds, even with perennials, as in grevillea and *Impatiens Sultani*.

Coming, now, to some of the principles that underlie the proper management of the house, it may be said, first of all, that the grower should *attempt to imitate a natural day.* There should be the full complement of continuous sunlight; there should be periodicity in temperature. From the lowest temperature before dawn, there should be a gradual rise to midday or later. As a rule, the night temperature should be 10° to 15° F. below the maximum day temperature in the shade. A high night temperature makes the plants soft and tends to bring them to maturity too early. It makes weak stems and flabby flowers. The temperature should change gradually: violent fluctuations are inimical, particularly to plants grown at a high temperature.

In greenhouse cultivation, *every plant is to receive individual care.* In the field, the crop is the unit: there we deal with plants in the aggregate. In the greenhouse, each plant is to be saved and to receive special care: upon this success depends. There should be no vacant places on the greenhouse bench; room is too valuable. All this means that every care should be taken so to arrange the house that every plant will have a chance to develop to its utmost perfection. Patient hand labor pays with greenhouse plants. The work cannot be done by tools or by proxy. Therefore, the gardener becomes skilful.

Every caution should be taken to *prevent the plants from becoming diseased or from being attacked by insects.* The greater part of insect and fungous troubles in the greenhouse is the result of carelessness or of mistakes in the growing of the plants. Determine what diseases or pests are likely to attack any plant; discover under what conditions these diseases or pests are likely to thrive; then see that those conditions do not arise. Keep the house sweet and clean. Destroy the affected parts whenever practicable. Then if trouble come, apply the fungicide or the insecticide. Remember that the very protection which is given the plants, in the way of equable conditions, also protects their enemies: therefore, it is better to count on not having the difficulties than on curing them. If uncontrollable diseases or pests have been troublesome, make a complete change of soil or stock before the next season, if practicable. At least once every year there is an opportunity to rid the place of pests. Nematodes may be frozen out. Many gardeners carry their troubles year by year by trying to fight them, when they might succeed by trying to avoid them.

Of course, the greenhouse man must provide himself with the best insecticides and fungicides, and with good apparatus. The efficiency of these materials and appliances has greatly improved in recent years, and most of the old pests may now be controlled.

The higher the temperature and the more rapid the growth, the greater the care necessary to insure good results. Plants grown under such conditions are soft and juicy. They are easily injured by every untoward circumstance, particularly by drafts of cold air. Let a draft of cold air fall on cucumbers or rapid-growing roses, and mildew will result in spite of bordeaux mixture and brimstone.

In dark weather, grow the plants "slow." If given too much heat or too much water, they become soft and flabby, and fall prey to mildew, green-fly and other disorders. A stocky plant is always desirable, but particularly in the dull weather and short days of midwinter: at that time, extra precautions should be taken in the management of the house.

Watering plants under glass requires more judgment than any other single operation. *Apply water when the plants need it,* is a gardener's rule, but it is difficult to follow because one may not know when they need it. Yet, if the gardener will put the emphasis on the word *need* he will at least be cautioned: novices often apply the advice as if it read: Apply water when the plants will stand it. *Water thoroughly at each application.* Mere dribbling may do more harm than good. Many persons water too frequently but not enough. Remember that in benches evaporation takes place from both top and bottom; and in pots it takes place from all sides. *Water on a rising temperature.* This advice is specially applicable to warmhouse stuff. Watering is a cooling process. *The foliage should not go into the night wet,* particularly if the plant is soft-growing or is a warmhouse subject. *Water sparingly or not at all when evaporation is slight,* as in dull weather.

In all greenhouse work, *see that the soil is thoroughly comminuted and that it contains much sand or fiber.* The amount of soil is small: see that it is all usable. In the garden, roots may wander if good soil is not at hand: in pots they cannot. The excessive watering in greenhouses tends to pack the soil, particularly if the water is applied from a hose. The earth tends to run together or to puddle. Therefore, it should contain little silt or clay. The practice of adding sand and leaf-mold to greenhouse soil is thus explained.

Ventilation is practised for the purpose of reducing temperature and of lessening atmospheric moisture. Theoretically, it is employed also for the purpose of introducing chemically fresh air, but with the opening and shutting of doors, and unavoidable leaks in the house, it is not necessary to give much thought to the introduction of mere fresh air. Ventilating reduces the temperature by letting out warm air and letting in cool air. The air should be admitted in small quantities and at the greatest distance from the plants in order to avoid the ill effects of drafts on the plants. Many small openings are better than a few very large ones. Ventilate on a rising temperature.

Most plants require shading in the summer under glass. *Shading is of use in mitigating the heat as well as in tempering the light.* A shaded house has more uniform conditions of temperature and moisture. If plants are grown soft and in partial shade, they are likely to be injured if exposed to bright sunlight. Sunscalding is most common in spring, since the plants are not yet inured to bright sunshine and strong sun heat. The burning of plants is due to waves (not bubbles) in the glass. Other things being equal, the larger the house the easier is the management of it. It is less subject to fluctuations of temperature and moisture. Greenhouses built against residences are specially liable to violent fluctuations; the body of air is small and responds to all external changes. L. H. B.

GREENS, CHRISTMAS. The Christmas greens industry has developed to an enormous extent within a few years. Some thirty years ago, when florists began to use lycopodium, a dozen barrels were all that was used in a single season in many of our larger cities. Today the output in the United States is many full carloads.

The materials now used, mentioned in something like their order of commercial importance, are holly, lycopodium (also known as bouquet green, ground pine, club moss), mistletoe, laurel, and cedar clippings. Other articles of similar utility are wild smilax, hardy ferns, needle pines, outdoor palm leaves, Florida moss, galax leaves and leucothoë sprays: these all come from the South.

Lycopodium is one of the oldest and commonest of decorative materials. During seasons of long-continued "Indian summer," a surplus is frequently gathered by careless pickers and thrown on the market. The choicest picked stock being obtainable only through the regular and well-established trade channels, such sources are usually the only ones in case of early snowstorms, which prevent the gathering of it. Choice stock from eastern Vermont, northern New York and Pennsylvania has usually been handled in large sugar-barrels, tied in carefully arranged bunches, weighing perhaps one-half to one pound each. These bunches are packed in the barrels in layers, with roots toward the center. The quantity is always limited and the price 25 to 35 per cent higher than the Wisconsin and Michigan stock. Lycopodium, as placed on the market from western sources, comes from the north-central part of the state of Wisconsin and is gathered mainly in the section extending from the northwest shores of Lake Michigan three-fifths of the way to the Mississippi River. The activities in this direction are conducted mainly in Oconto, Shawano, Marathon, Langlade, Lincoln, Forest, Oneida, Taylor, Price and Vilas Counties. The section from which lycopodium is picked annually moves northward as the country becomes settled and as the woods and swamps are depleted. This article is also gathered in a few spots in the northern peninsula of Michigan, and in Pine, and Carleton Counties in Minnesota. Surplus stock of this plant is sometimes carried over until the following season when it is soaked and dyed green and made up into wreathing. The same article carried over from

LI. A home greenhouse.

Christmas in the usual 100-pound crates loses its fresh color and dries down to a weight of about fifty pounds. There is some foreign demand for this plant in the German cities for use in the artificial-flower trade. This plant seems to thrive best in moist, shaded localities, and when plucked out by the roots, as is done when gathering, is not replaced by new growth of its kind. More open situations and drier ground produce lycopodium of a lighter and yellowish color, and consequently of less decorative value. Indians pick the best green, but are unreliable when exact dates must be met. The average season's output from Wisconsin is perhaps thirty-five carloads, or 150 to 200 tons.

The use of holly in a commercial way has grown from a very small beginning to its present proportions within fifteen years. Until the last twenty years most of the holly was handled by wholesale seedsmen and florists. Within that time the sale of holly has been taken up by the produce commission houses in large cities, thereby trebling the volume, but reducing the quality. Delaware and Maryland furnish the best stock of what is known as eastern holly, while Tennessee and some other parts of the South ship what is usually an inferior quality. Holly is almost always packed in uniform cases 2 by 2 by 4 feet. Freezing, while packed in cases, damages it but little, provided the holly be allowed to thaw out in a very cool and preferably dark place, where the temperature is not allowed to exceed 45° F. If, however, frozen holly is shipped in warm express cars, the foliage may turn black in a night. English holly has occasionally been imported into the United States and into Canada, but never satisfactorily commercially. For red winter berries, *Ilex verticillata*, a deciduous holly which grows in large quantities in Michigan, is now a much-sought decorative material.

Both holly and lycopodium are becoming more scarce every year, and the market has probably advanced permanently 20 to 30 per cent in the last two or three years.

Mistletoe branches as used in America (a very little is imported from France) are collected chiefly in New Mexico and Oklahoma, and small quantities from Tennessee, Kentucky or Arkansas. It is now usual to ship this in heavy pasteboard cases containing twenty-five to fifty pounds. The western or central states probably use 15,000 to 20,000 pounds from the states mentioned. Mistletoe is easily very seriously injured from freezing in transit.

Cedar clippings are now but little used during the holiday season, but on other occasions, when open-air decorations are desired, they are frequently made into roping or wreaths.

Wild smilax, in light cases, usually in three sizes, is shipped by express mostly from Alabama and Georgia. It is as liable to injury by freezing as mistletoe, but is not damaged if allowed to thaw out gradually before removal from the case. The use of this article by the wholesale cut-flower dealers is increasing. There is probably $20,000 worth used annually and some carload shipments are made. It is readily perishable and the wholesale dealers put it in ice storage where it keeps for two to three weeks. They do not usually keep it in stock except during the holiday season.

Boxwood clippings of lengths from 12 to 18 inches have become quite an article of commerce. These are gathered from Maryland, Virginia, West Virginia and other similar localities and are used mainly in the cut-flower trade for making wreaths and for mixing with fresh flowers. The gathering and shipping of this article for the above purpose was begun four or five years ago. The trade has increased rapidly and perhaps fifty tons or more were used in 1911. It will probably take but a short time to exhaust the old gardens where this plant has been growing in the sections mentioned, as it is not to be had except around old homesteads where it was planted years ago.

The use of laurel is increasing largely during the past five years and it is now shipped from Maryland, Delaware, Virginia and New Jersey, both in bulk in short sprays in cases, similar to those used in holly cases, and in wreathing in coils usually containing 100 yards. Shipments are made from the above sections to the northern and western states.

Hardy ferns are also marketed through the wholesale cut-flower merchants. These are gathered in Massachusetts and Michigan and kept in storage the entire year, not being so perishable as wild smilax. Wisconsin is now producing as many ferns as Michigan, or perhaps more.

Among the most artistic materials for Christmas decoration are galax leaves and leucothoë sprays. Galax grows in the mountains from North Carolina to Georgia, and nowhere else in the world.

For further particulars concerning this industry, see American Florist 14:598–600 (1898). For the artistic side of Christmas decoration, see illustrated articles by F. Schuyler Mathews in American Florist 8:484 and 9:493.

J. C. Vaughan.

GREENS, EDIBLE, or POT-HERBS. This term greens is generally applied in America to any pot-herb, that is to say, to any green herbage which is cooked and served separately from the other principal and secondary dishes of a square meal. The term "greens" is commonly used for the mess of cookery which is brought to the table. It is not so often applied to the plants growing in the garden. In the garden, perhaps, they are herbs—pot-herbs—although this term is not so much employed as it conveniently might be. Greens are served early in the spring, when the appetite craves anything which tastes like out-of-doors.

All sorts of plants are used as pot-herbs. Almost anything which shows a succulent growth in the spring is likely to be tried by somebody. Turnip tops, potato leaves, pig-weeds, purslane, and many other apparently impossible herbs, are often impressed into the service. The really good pot-herbs are comparatively few, however. Probably the best are dandelion, spinach, mustard (various species), endive, chard, beet-top and kale.

The following plants have been more or less used as pot-herbs:

Buck's-horn Plantain, *Plantago Coronopus.*
California Peppergrass, *Brassica japonica.*
Cardoon, *Cynara Cardunculus.*
Chard, *Beta vulgaris.*
Chervil, *Anthriscus Cerefolium.*
Chicory, *Cichorium Intybus.*
Chinese Amaranth, *Amarantus gangeticus.*
Chinense Artichoke, *Stachys Sieboldii* (*S. affinis* or *S. tuberifera*).
Chinese Cabbage, *Brassica Pe-tsai.*
Chinese Cabbage, *Brassica chinensis.*
Chinese Mustard, *Brassica juncea.*
Chives, *Allium Schoenoprasum.*
Corn Salad, *Valerianella olitoria.*
Cress, *Lepidium sativa.*
  Meadow Cress, *Cardamine pratensis.*
  Pará Cress, *Spilanthes oleracea.*
  Upland Cress, *Barbarea vulgaris* and *B. præcox.*
  Other so-called Cresses, as *Lepidium chilense, Lepidium piscidium, Lepidium virginicum, Senebiera pinnatifida, Nasturtium indicum, Gynandropsis pentaphylla.*
Dandelion, *Taraxicum officinale.*
Dock, *Rumex,* several species.
Endive, *Cichorium Endivia.*
Globe Artichoke, *Cynara Scolymus.*
Good King Henry, *Chenopodium Bonus-Henricus.*
Goosefoot, *Chenopodium,* mostly *C. album.*
Ice Plant, *Mesembryanthemum crystallinum.*
Italian Corn Salad, *Valerianella eriocarpa.*
Kale, *Brassica oleracea.*
Lettuce, *Lactuca* (especially the wild species, some of which are excellent).
Malabar Nightshade, *Basella alba* and *Basella rubra.*
Mustard, *Brassica* species.
Nasturtiums, *Tropæolum* species.
Orach, *Atriplex hortensis.*
Parsley, *Petroselinum.*
Pepper-grass, *Lepidium* species.
Pigweed, *Amarantus* species.
Pokeweed, *Phytolacca decandra.*
Quinoa, *Chenopodium Quinoa.*
Rocket Salad, *Eruca sativa.*

Rosella, *Hibiscus Sabdariffa.*
Salad-Burnet, *Porterium Sanguisorba.*
Sorrels, various, *Oxalis crenata, O. tetraphylla.*
Spinach, *Spinacia oleracea.*
Tuberous-Rooted Chinese Mustard, *Brassica napiformis.*
Turnip, *Brassica Rapa.*
Winter Purslane, *Montia perfoliata.*

Culture.—Pot-herbs are wanted at the earliest possible moment in the spring. They are, therefore, often grown in hotbeds, frames, or in greenhouses (see *Spinach, Dandelion, Mustard,* etc.). They must be succulent and tender. It is necessary, on this account, that they be quickly grown in loose, very rich, well-drained soil, with plenty of water. Specific directions for the cultivation of the various plants will be found under the several heads. F. A. Waugh.

GREGÒRIA: *Douglasia.*

GREÌGIA (Major-General Greig, Russian horticulturist). *Bromeliàceæ.* A few species of large Andine, terrestrial or rock-loving herbs, allied to Cryptanthus, from which it differs in its simple rather than panicled infl. Fls. perfect; sepals free or lightly joined at the base, linear or ovate-lanceolate or almost subulate; perianth with free elliptical segms. rounded at apex; stamens shorter than petals or scarcely exceeding them; petals rose-color or white suffused with rose, becoming brownish. **G. sphacelàta,** Regel (*Billbérgia sphacelàta,* R. & S. *Bromèlia sphacelàta,* Ruiz & Pav.). Stout pineapple-like plant, 3 ft., with strong spiny-margined spreading or recurving lvs.: fls. rose-color, in dense heads in the axils of the lvs., the outer bracts spiny and very acute. Summer. Chile.—A showy plant. L. H. B.

GRENADIN or GRENADINE: A type of carnation.

GREVÍLLEA (Charles F. Greville, once vice-president of the Royal Society of England, and a patron of botany). *Proteàceæ.* Trees and shrubs, of about 200 species, mostly Australian, one of which is commonly cultivated in this country as a decorative pot-plant and also in the open in southern California and elsewhere in warm regions.

Leaves alternate, very various: fls. small, perfect, mostly in pairs in the clusters or racemes, apetalous, the calyx with 4 recurved parts; stamens of 4 sessile perfect anthers borne on the sepals; style 1, long and curved: fr. a follicle, with 1 or 2 winged orbicular or oblong flat seeds. The fls., sometimes showy and ornamental, are terminal and axillary, the racemes sometimes umbel-like. The fls. of some species produce honey. Some species yield useful timber.

A. *Racemes secund, many-fld.: lvs. much cut or compounded.*

robústa, Cunn. Silk Oak. Fig. 1768. One of the most popular of all fern-leaved pot-plants. When young (from 2–5 ft. high) it makes a most graceful subject. In glasshouses it is not grown to large plants, and, therefore, little is known of the great size which it attains in its native forest. According to Von Mueller, it is "indigenous to the subtropical part of E. Austral., rising to 150 ft., of rather rapid growth, and resisting drought to a remarkable degree; hence one of the most eligible trees even for desert culture, though naturally a sylvan plant. The wood is elastic and durable, valued particularly for staves of casks, also for furniture. The richly developed golden yellow trusses of fls. attract honey-sucking birds and bees through several months of the year. The seeds are copiously produced and germinate readily. Rate of growth in Victoria, 20–30 ft. in 20 years. In Ceylon it attained a stem-circumference of 5 ft. in 8 years." In Calif. and S. Fla. it is a street lawn tree, although the branches break easily in exposed places. When grown in the open, it will stand some frost. As a glasshouse plant it is grown almost wholly from seeds, and is used in its young state; as the plant becomes old, it loses its leaves and becomes ragged below. It thrives in the temperature suited to geraniums or roses, and it stands much hard usage and neglect. It is popular as a window subject. Best results with grevillea are usually secured by raising a fresh stock every year, from seed sown late in winter or in spring. The following winter or spring they will be in 4–6 in. pots, and will be in their prime. The young plants need frequent repotting to keep them in good condition. *Grevillea robusta* has come to be generally known as a florists' plant within the past thirty years. Lvs. twice-pinnatifid (or the pinnæ deeply pinnatifid), or nearly 3-pinnate under cult., the ultimate divisions narrow and pointed and sometimes lobed, pubescent: racemes 3–4 in. long, solitary or several together on short leafless branches of the old wood; fls. orange, glabrous, the tube ¼in. long, the parts revolute: fr. about ¾in. long, broad, very oblique. B.M. 3184. G. 2:615; 8:680. G.L. 24:40. A.G. 14:115. A.F. 4:413.—In the W. Indies the plant is much grown, and it is often trimmed to desired shape. In exposed places the foliage becomes golden in cast. Var. **compácta,** Hort., is a condensed dwarf form with handsome foliage, G.C. III. 49:375. G.M. 54:452. G. 33:393. F. E. 31:1259. Var. **pyramidàlis,** Hort., is offered abroad. Var. **Fórsteri** (*G. Fórsteri,* Hort.) is a form of *G. robusta.* It has silvery foliage, large trusses of deep bright red fls., and much stronger growth. R.B. 24:3.

1768. Grevillea robusta. (×⅙)

Thelemanniàna, Hueg. (*G. Prèissii,* Meissn.). Spreading shrub, the young growths soft-tomentose: lvs. 1–2 in. long, pale or glaucous, pinnate, the lower pinnæ usually divided, segms. linear: racemes terminal, rather dense, 1½ in. or less long; fls. pink with green tips, few-hairy outside and bearded inside, the tube about ¼in. long: fr. about ½in. long, smooth. B.M. 5837. R.H. 1882:456. J.H. III. 42:497. H.U. 6:193. G.W. 5:499.—Now popular in Calif.

Bánksii, R. Br. Tall shrub or slender small tree, with branches rusty-tomentose: lvs. 4–8 in. long, pinnate or deeply pinnatifid, the segms. 3–11 and broad-linear or lanceolate, margins revolute: racemes terminal, erect and dense, 2–4 in. long; fls. red, tomentose outside and glabrous inside: fr. about 1 in. long, obliquely ovate. B.M. 5870. G.C. III. 16:15.—Offered abroad.

AA. *Racemes not secund, dense and usually short, sometimes panicled: lvs. less divided, often only lobed.*

Hilliàna, F. Muell. Large tree, with minutely tomentose young branches: lvs. 6–8 in. or more long, sometimes entire and obovate-oblong or elliptical and very obtuse, sometimes deeply divided or even pinnatifid: fls. red, small and very many in dense cylindrical racemes 4–8 in. long, silky outside, glabrous or nearly so inside: fr. nearly 1 in. long, slightly compressed. B.M. 7524.—Pink and white varieties are mentioned.

glabràta, Meissn. (*G. Mánglesii*, Hort.). Shrub, glabrous, slender: lvs. 1–1½ in. long, broadly cuneate, shortly and acutely 3-lobed: fls. white, in axillary racemes equaling the lvs. or the upper racemes panicled, the perianth glabrous, the tube much exceeding the globular limb.—Offered abroad as a bright green ornamental foliage plant of drooping habit.

There are no other grevilleas in the American trade, but following are accessible portraits of other species: *G. acanthifòlia*, Cunn. B.M. 2807.—*G. alpéstris*, Meissn. (G. alpina var. Lindl.). B.M. 5007. R.H. 1887:108. R.B. 23:145.—*G. annulífera*, Muell. B.M. 6687.—*G. arendria*, R. Br. (G. canescens, R. Br.). B.M. 3185.—*G. asplenifòlia*, Knight. B.M. 7070. R.H. 1882, p. 245 (as G. longifolia).—*G. bipinnatífida*, R. Br. B.M. 8510.—*G. Càleyi*, R. Br. B.M. 3133.—*G. canéscens*, R. Br.=G. arenaria.—*G. ericifòlia*, R. Br. B.M. 6361.—*G. fasciculàta*, R. Br. B.M. 6105.—*G. Hookeriàna*, Meissn. B.M. 6879.—*G. intricàta*, Meissn. B.M. 5919.—*G. juniperìna*, R. Br. (G. sulphurea, Cunn.). G.C. II. 26:469.—*G. lavandulàcea*, Schlecht. (G. rosea, Lindl.). I.H. 2:61. J.F. 3:288.—*G. lineàris*, R. Br. B.M. 2661.—*G. longifòlia*, R. Br.=G. asplenifolia.—*G. macróstylis*, Muell. B.M. 5915.—*G. pulchélla*, Meissn. B.M. 5979.—*G. punícea*, R. Br. B.M. 6698.—*G. rosmarinifòlia*, Cunn. B.M. 5971. G.C. II. 5:529. G. 35:389.—*G. serícea*, R. Br. (G. dubia, R. Br.). B.M. 3798.—*G. sulphùrea*, Cunn.=G. juniperina.

L. H. B.

GRÈWIA (Nehemiah Grew, of Coventry, 1628–1682, author of a work on anatomy of plants). *Tiliàceæ.* Two or three woody plants slightly cultivated in southern Florida.

A genus of about 70 species of trees and shrubs in the warmer parts of the world, often having stellate pubescence: lvs. entire or serrate, 1–9-nerved: fls. yellow or rarely purple, in axillary, few-fld. cymes or terminal panicles; petals 5, with pits or glands inside at the base; stamens indefinite; ovary 2–4-celled: drupe 1–4-stoned. **G. Cáffra,** Meissn., from Natal, was intro. by Reasoner Bros. in 1891. A bushy plant with young shoots and lvs. glabrous and with purple star-shaped fls. borne during most of the year. **G. denticulàta,** Wall., from India, was never described. Under this name Reasoner cult. a plant "resembling a mulberry in growth, which bears enormous quantities of acid drupes, about the size of cranberries; used for pickling." **G. oppositifòlia,** Roxbg., is a rough, much-branched tree, with distichous, crenate-serrate lvs. and fls. in umbellate cymes, borne opposite the lvs.: fls. yellowish, the oblong petals half the length of the sepals. The species are little known in Amer.

N. Taylor.†

GRÈYIA (after Sir George Grey, once Governor of Cape Colony). Often spelled *Greya*. *Melianthàceæ.* A small tree from Natal, which bears large spikes of pendulous, five-petaled, scarlet flowers, and is cultivated outdoors in southern California and abroad under glass in many botanic gardens.

Species probably 3, but only 1 appears to be in cult.; in R.H. 1894:252 this plant is shown at its best, with a spike 6 in. long and 2–3 in. wide, containing probably over 100 fls., each ¾in. across. In France this tree flowered from the end of autumn throughout the winter. The long-exserted stamens with reddish purple anthers make a striking feature. The structure of the fls. is so peculiar that Harvey referred the genus doubtfully to the saxifrage family. In European greenhouses, greyia is a shrub requiring full sunlight, thorough ripening of the wood and a season of rest before flowering. In Natal it flowers in Aug. or Sept., which is early spring there. Europeans recommend a sandy loam. Prop. by seeds or by cuttings from half-ripened wood.

Sútherlandii, Hook. & Harv. Small tree, with thick, naked branches and light-colored bark: lvs. clustered at the ends of the branches, 2–3 in. long, orbicular, ovate or oblong, deeply cordate at base, toothed; petiole 9–12 lines long: fls. bright crimson; disk cup-shaped, with 10 marginal teeth, each crowned by a peltate gland; stamens 10; ovary laterally 5-lobed, 5-celled; ovules numerous, in 2 series in the inner angle of the cells: fr. capsular, 5-valved; seeds albuminous. B.M. 6040. R.H. 1894:252. G.C. II. 19:625; III. 43:138. J.H. III. 30:101.

N. Taylor.†

GRÌAS (name refers to the fr. being edible). *Lecythidàceæ.* Tall W. Indian trees, with branches short or none and very large alternate simple lvs., one of them known for its edible fr.: fls. large, white or yellow, lateral; calyx entire in bud, but becoming 2–4-lobed or torn; petals spreading, 4 or 5; stamens many, in many or several rows on the disk, the inner ones smaller, the fleshy filaments conniving into a globular involute body, the anthers small and the cells distinct: fr. fleshy, ovoid.—Species about 4. *G. cauliflòra*, Linn., produces the Anchovy pear: lvs. 2–4 ft. long, lanceolate-acuminate, entire, drooping, glossy, borne in palm-like tufts or heads on the top of the st. or ends of branches.: fls. on short branching peduncles from the old st. far below the lvs., fragrant, 2 in. across, yellow: fr. ovoid, 2–3 in. long, 8-grooved, brown, fleshy, with 1 seed, said to be edible. W. Indies. B.M. 5622.

L. H. B.

GRIFFÍNIA (after William Griffin, who brought these plants from Brazil). *Amaryllidàceæ.* Brazilian bulbs, with distinct foliage, and flowers, about 2½ inches across, which are more or less tinged with lilac or rose.

Leaves usually petioled, and with a very broad blade: perianth-tube none or very short, the 3 lower segms. narrower than the upper; ovary 3-celled; stigma capitate, rarely 3-fid; umbel 6–15-fld. Griffinia is distinguished from many other genera by its 2 ovules, which are basal and collateral.—Seven species. Like many other genera of the amaryllis family, bulbs of flowering size are too costly for general use. Very doubtfully in cult. in Amer.

A. *Stigma capitate.*

hyacínthina, Herb. Bulb globose: lvs. 6–9 in. long, 2–3 in. broad, rounded at the base to a channeled petiole as long as the blade: scape 1–2 ft. long; pedicels none or very short; stamens much shorter than the segms. B.R. 163 (as *Amaryllis hyacinthina;* upper segms. tinged blue, lower ones nearly white). J.H. III. 31:371; 55:325. G.M. 47:45. Var. **máxima,** Gn. 50, p. 209, is probably the best garden form. Called "blue amaryllis" in some catalogues.

AA. *Stigma distinctly 3-cut.*

Blumenàvia, Koch & Bouché. Bulb ovoid: lvs. 4–5 in. long, cuneately narrowed to a petiole, shorter than the blade: scape 6–8 in. long; pedicels ½in. long; stamens as long as the perianth. B.M. 5666 (veins rose-colored). R.H. 1867:32. Gn. 50:208 (veined and flushed with rose).

N. Taylor.†

GRINDÈLIA (Hieronymus Grindel, of Riga and Dorpat; died 1836). *Compósitæ.* Hardy plants sometimes cultivated for their showy yellow flowers, which are 1½ to 2 inches across and borne freely all summer.

Herbs, sometimes shrubby, of coarse habit, mostly natives of the U. S. west of the Mississippi: lvs. sessile or partly clasping and usually serrate and rigid: heads terminating the branches, solitary or in cymes or panicles; involucre bell-shaped or hemispheric, the bracts many-ranked. The plants often have a sticky balsam, especially the heads before and during flowering, whence they are called "gum-plants" in Calif., particularly *G. robusta*, which is the common one. The two species first described below have roots that are perennial and short-lived, but sometimes annual. These plants are also glabrous, and have firm or rigid lvs. This genus contains 2 plants from which a fluid-extract is obtained that is used externally as an antidote for poisoning by "poison ivy."—Species about 25.

Grindelias are of the easiest culture. They are propagated by division, cuttings or seed. *G. squarrosa* is hardy in the East: *G. robusta* is sold in California. They are best for wild places and trying situations. *G. squarrosa* grows freely in all soils but it does best in a light, open, moderately rich soil. In California it is common on dry hills. According to John S. Wright, both species grow in salt marshes and on alkaline soil, being indiscriminately gathered for medicinal purposes. The extract is also tonic and sedative, and is used in asthma. The rays are numerous, sometimes thirty, about ½-inch long.

squarròsa, Dunal. Shrubby, smooth, branched from base, 1–2 ft. high: lvs. dark or bluish green with clasping bases: fl.-heads sticky: outer achenes usually squarely truncate and even at summit. Manitoba to Mex. B.M. 1706 (as *Donia squarrosa*). Mn. 10:145.

robústa, Nutt. Gum-Plant. Herbaceous: lvs. larger and more rigid, broadly cordate-oblong, obtuse: achenes all, or some outer ones, 1-toothed or bordered at the summit.—Flowers throughout the Californian winter. Collected stock is offered.

pàtens, Greenm. (*G. robústa* var. *pàtens*, Gray). A stiff erect perennial with many single-headed branches: lvs. rough-hairy, narrowly oblanceolate, toothed: heads about 1 in. wide, the achenes thin, obcordate at the summit. Calif. G.C. III. 27:59.

Wilhelm Miller.
N. Taylor.†

GRISEBÁCHIA: *Howea.*

GRISELÌNIA (after Franc Griselini, Venetian botanist, middle of eighteenth century). Including *Decóstea*. *Cornàceæ*. Woody plants with large, glossy, laurel-like foliage, rarely cultivated in the South, and nearly hardy at Washington.

Trees, shrubs or climbers from New Zeal., Chile and Brazil, with lvs. alternate, often unequal-sided, thick and leathery: fls. minute, in glabrous or pubescent racemes or panicles; calyx very small, 5-toothed, the petals 5, imbricated; stamens 5, with subulate filaments: fr. baccate, 1- or rarely 2-celled.—Six or seven species. Related to Garrya, from which it differs in the alternate lvs. Little cult. in Amer.

littoràlis, Raoul. Tree, 30–50 ft. high, with brown-hairy twigs: lvs. ovate or oblong, wedge-shaped or narrowed into a petiole; veins obscure beneath: fls. in axillary panicles, equaling or slightly shorter than the lvs. New Zeal. G.W. 14, p. 323.

lùcida, Forst. f. Shrub, 3–25 ft. high: lvs. obovate or oblong, very unequal at the base; veins distinct beneath: fls. in axillary panicles, usually shorter than the lvs. New Zeal. Not cult. in Amer. Var. **macrophýlla** (*G. macrophýlla*, Hort.), is a large, more orbicular-lvd. form.—*G. lucida* is prized in Eu. for apartments or residences. Showy. Requires shade and moisture. Sometimes epiphytic. N. Taylor.†

GROMWELL: *Lithospermum.*

GROSSULÀRIA (from *grossulus*, a small fig, from the resemblance of the fruit). *Saxifragàceæ*. An old name for the gooseberries recently (N. Amer. Fl. 22, pt. 3. 1908) reinstated by Coville and Britton as a genus coördinate with Ribes, the currants. As distinguished from Ribes, Grossularia is defined by the flowers having an evident hypanthium or cup-shaped receptacle, the pedicels not jointed and the fruit not disarticulating, different disposition of bractlets on the pedicel, and the plants bearing spines at the nodes. Under this disposition, the English gooseberry becomes *G. reclinàta*, Mill. or *G. Uvacríspa*, Mill., and the native gooseberry of the Downing type is *G. hirtélla*, Spach. See *Ribes*. L. H. B.

GROUND CHERRY: *Physalis;* in the Old World *Prunus Chamæcerasus*. **Ground Hemlock** or American yew: *Taxus canadensis*. **Ground Ivy:** *Nepeta Glechoma*. **Ground Laurel:** Old World name for *Epigæa repens*. **Groundnut:** *Apios* and *Panax;* also Old World name for peanut or goober (*Arachis*). **Ground Pine:** *Lycopodium*. **Ground Pink:** *Phlox subulata.*

GROUNDSEL: *Senecio.* **Groundsel Tree:** *Baccharis halimifolia.*

GRUMICHÀMA: *Eugenia brasiliensis.*

GUÀIACUM (W. Indian name). *Zygophyllàceæ*. Guaiacum (gwaí-a-cum) is kept in drugstores, and the tree which produces the resin used in medicine has a hard, heavy wood. Both the species below are the source of the lignum-vitæ of commerce which is used so extensively for blocks and pulleys, rulers, and the like. It is cult. to a very slight extent in S. Calif. and in Trop. Fla. for ornamental value. The genus has about 4 species of trees or shrubs, Trop. American, and all have hard wood and abundant resin: lvs. opposite, abruptly pinnate, leathery; lfts. 2–14, entire: peduncles borne in pairs between the deciduous stipules, 1-fld.; fls. blue or purple, not showy; sepals 4–5, deciduous, unequal; petals 4–5, broadly obovate; stamens 8–10, inserted in the short, inconspicuous disk.

1769. Cattley guava. (×½)

officinàle, Linn. Middle-sized or low tree, inhabiting arid plains from the Fla. keys to Venezuela: lfts. in pairs, evergreen, ¼–½in. long, obovate or oval, blunt: sepals oval, hairy, thrice exceeded by the petals.

sánctum, Linn. Similar in aspect, but the lvs. obliquely lanceolate-elliptic, and the smooth sepals about half as long as the petals. W. Indies.—Not much cult. in Amer. The wood of both species is very valuable. N. Taylor.†

GUAR. An annual forage plant (*Cyamopsis tetragonoloba*, Taub.), of the Leguminosæ, has been tried somewhat in this country with promise. It appears to be adapted to the warmer parts of the country, requiring about the same conditions as the cowpea. It is from India.

GUAVA. The name guava is applied to the fruit of various species of Psidium, frequently with the addition of a qualifying word such as apple, pear, Cattley, to distinguish different species and varieties. In Spanish it is guayaba, in Portuguese goiaba, and in French goyave (the plant goyavier). In Brazil the name araça, with qualifying words, is applied to a number of wild species.

The common guava of the tropics is *Psidium Guajava*, Linn., of which there are numerous varieties. Although the native home of this species is in tropical America, it is now widely distributed throughout the warmest regions of the globe. Under favorable conditions it becomes a tree 25 to 30 feet in height; its bark is smooth, greenish brown in color, while the leaves are opposite, oval, smooth, light green, the veins depressed above and prominent below. The flowers, which are produced in the axils of the leaves, are about an inch in diameter, with four incurved white petals and a large tuft of white stamens tipped with yellowish anthers.

The fruit varies in shape from spherical to pyriform, and in diameter from 1 to 4 inches. Commonly it is oval or slightly pyriform, and about 2 inches in diameter. The thin light yellow skin surrounds a layer of finely granular pulp, inside of which is a mass of softer pulp in which the small hard seeds are embedded. The color of the flesh varies from white through shades of salmon to deep pink, according to the variety; its flavor when fully ripe is sweet or slightly acid, and nearly always somewhat musky. The aroma is characteristic and rather penetrating; while objectionable to some persons it is very agreeable to others.

The fruit is eaten in many ways,—out of hand, sliced with cream, stewed, preserved, and in shortcakes and pies, but it is most highly valued for the manufacture of jams and jellies. In several tropical countries the manufacture of guava jelly forms quite an important industry. When well made, it is deep wine color, clear, of very firm consistency, and retains something of the peculiar musky flavor which characterizes the fruit, and which gives guava jelly an individuality which is its greatest asset. In Brazil a thick jam, known as goiabada, is made from the fruit and sold in large quantities throughout the country. A similar product is manufactured in the West Indies and Florida under the name of guava cheese.

The plant is cultivated to a limited extent in southern California, where it is frequently listed under the name of lemon guava. It is too tender for the colder sections of the state. In Florida it is not only cultivated in gardens, but is found in a semi-naturalized condition in some sections and has become a pest. The same is true in many other regions; the plant grows so readily from seed that it is sometimes difficult to prevent its spreading to places where it is not desired when the seeds are scattered by birds or other agencies.

The Cattley or strawberry guava, *P. Cattleianum*, Fig. 1769, is also a well-known fruit in this country. In California it is widely cultivated because of its superior hardiness, withstanding temperatures as low as 22° F. without injury. It does not grow to such large size as *P. Guajava*, but under favorable conditions forms an arborescent shrub 15 to 20 feet in height. Unlike *P. Guajava*, its leaves are thick, leathery, and somewhat glossy, in size rarely over 2½ inches in length and in form obovate-elliptical. The fruit, which is usually produced in great abundance, is broadly pyriform to spherical, 1 to 1½ inches in diameter. The skin is deep purplish maroon, the flesh translucent yellowish white, very soft and melting in texture. The seeds are rather numerous, irregularly oval in form. The flavor lacks the pungency of *P. Guajava*, and a resemblance, real or imagined, to that of the strawberry has suggested the common name of "strawberry guava." Jelly made from this fruit, while lacking the pronounced flavor of that made from *P. Guajava*, is nevertheless highly esteemed in California, most of the fruit being utilized for jelly-making.

While rather slow in growth, the plant frequently begins to bear fruit the second or third year from the seed. A horticultural form of this species, *P. Cattleianum lucidum*, generally listed by the trade as *P. lucidum*, is grown both in Florida and California, though not so extensively as *P. Cattleianum* itself. The chief difference between this form and the type lies in the color of the fruit, which in place of maroon is deep sulfur-yellow. The flavor, if anything, is a little milder and less pungent. It is a meritorious form, worthy of wider cultivation.

The "pineapple guava," of California, is *Feijoa Sellowiana*, a South American myrtaceous fruit not properly called a guava, perhaps, but so closely resembling some of the guavas in growth and fruit as to suggest this name. See *Feijoa*. Several other species of Psidium are grown in this country to a limited extent, some of them having been recently introduced. Tropical America is rich in species of Psidium, Brazil alone possessing a large number of economic value. Most of these are still in the wild state and capable of vast improvement by selection and breeding.

The culture of the guavas presents few difficulties. Nearly all species succeed on a variety of soils, requiring only that good drainage be provided. While propagation is nearly always by seed, some vegetative method must be used to perpetuate desirable varieties. This is especially important with *P. Guajava*, in which there is more variation than in *P. Cattleianum*, and desirable forms do not come true from seed. Grafting has been successfully performed but never widely practised. In California, budding has been quite successful, with large stocks an inch or more in diameter and square or oblong patch buds about 1½ inches in length. This method, however, does not seem very suitable for commercial use. Shield budding has been successful in a few instances, the operation being performed as with citrus, and it is this method which probably offers the greatest advantages. Propagation by cuttings is also possible, when half-ripened wood is used and bottom heat is available. All these methods have been practised to a very limited extent, seed-propagation being practically the only method used in most tropical countries. Seeds retain their vitality for some time, but should be planted as fresh as possible, using a light sandy loam and taking care to avoid over-watering when the young plants appear. When the second leaves have formed, the plants should be potted off and carried along in pots until they are transplanted into permanent positions, since they are somewhat difficult to transplant from the open ground. Planting should be done in late spring.

In California *P. Guajava* frequently suffers from the attacks of the black scale (*Saissetia oleæ*), which must be kept in check by fumigation or spraying. In other countries this plant seems remarkably free from insect pests or fungous diseases, and this is true also of the Cattley guava. The fruits are sometimes injured by the Mediterranean fruit-fly, and a scab has been observed in Brazil which affects them prejudicially. As a rule, however, the plants require little attention.

F. W. Popenoe.

GUAZÙMA (name of Mexican origin). *Sterculiàceæ.* A few Trop. American trees, allied to Theobroma, with small white, pink or yellow fls. in short-peduncled, axillary cymes. Calyx mostly 3-parted; petals 5, 2-parted; stamen-cup about 10-lobed, the lobes alternating with petals and bearing 2–3 fertile anthers, the staminodia 3-angled; style 5-parted: fr. a 5-valved nut the size of a filbert: lvs. 2-ranked, serrate: fls. small. Theobroma has a berry-like fr., entire lvs., fascicled or solitary fls., and a different staminal column. G. **ulmifòlia,** Lam., the "guacima" of Mex., is offered in Calif. It becomes a large tree: branchlets powdery: lvs. ovate to oblong-lanceolate, somewhat pointed, oblique at base, powdery beneath when young but becoming glabrous: nut nearly globular, with 5 furrows. Said to yield medicinal preparations. *G. tomentòsa,*, Kunth, is a small tree in W. Indies, apparently not cult. here.

L. H. B.

GUETTÁRDA (J. E. Guettard, 1715–1786, physician, mineralogist and botanist in France). *Rubiàceæ.* Forty to fifty tropical and subtropical shrubs of both the eastern and western hemispheres, chiefly the latter, two of which are offered for ornament in southern California.

Leaves opposite or verticillate, ovate or oblong, petiolate or nearly sessile: fls. in axillary more or less forked cymes, sometimes polygamo-diœcious, 4–9-merous; calyx continued beyond ovary into a cup-shaped or bell-shaped rim; corolla salverform, with long tube and rounded or oblong segms.; stamens 4–9, inserted in the tube or throat, not exserted; ovary 4–9-celled: fr. a thin-fleshed globular or obtusely angled drupe.

uruguénsis, Cham. & Schlecht. Lvs. 2 in. long, half as wide, elliptic-oblong, somewhat pilose above and more or less tomentose beneath; stipules lanceolate-triangular, caducous: corolla-tube ¼in. or less long, the 5 lobes roundish; calyx-limb very short: fr. an oblong 3–4-seeded drupe.—Cent. Brazil, Uruguay, Argentina; a small tree, with sericeous corolla, and fr. the size of a cherry which is said to be edible.

speciòsa, Linn. A littoral evergreen tree: lvs. broadly ovate with an obtuse or cordate base, acute at apex, pubescent beneath, 5–10 in. long: fls. polygamous, white, in long-peduncled cymes that usually arise in the axils of fallen lvs.; calyx villous; corolla pubescent, 1½ in. or less long and the limb (with obovate segms.) 1 in. across: fr. orange, nearly globular, obscurely lobed or angled, said to be edible. Tropics in eastern hemisphere. B.R. 1393.

L. H. B.

GUEVÌNA: *Gevuina.*

GUICHENÒTIA (Antoine Guichenot, French gardener, according to some; from Guichen Bay, New Holland, according to others). *Sterculiàceæ.* A few tomentose shrubs in extra-tropical Austral., little known in cult. as greenhouse shrubs. Lvs. narrow and entire, revolute. with leafy stipules: fls. small, in simple racemes opposite the lvs.; petals 5, small and scale-like; stamens 5; ovary 5-celled, the style simple: fr. a short 5-valved caps. *G. ledifòlia,* Gay, has several white fls. in the raceme: lvs. oblong-linear, obtuse: calyx ⅓in. or less long. *G. macrántha,* Turcz., has much larger purplish fls. in racemes of 2 or 3. B.M. 4651. J.F. 3:279.

L. H. B.

GUILIÉLMA: *Bactris.*

GUIZÒTIA (after Guizot, the celebrated historian). *Compósitæ.* Annual herbs (of about five species) from tropical Africa, one of which has some economic interest from its oil-producing seeds.

The plants have yellow heads, about 2 in. across, with 8 broad, 3-toothed rays and a leafy outer involucre. Seeds can be secured by the pound from S. Fla., and they are listed among miscellaneous agricultural seeds in a few of the largest European catalogues. The plant is cult. in India for the oil.

abyssínica, Cass. (*G. oleífera,* DC. *Verbesìna satìva,* Roxbg.). Erect, annual, nearly smooth: lvs. opposite, lanceolate, clasping, remotely serrate: heads about ¾in. wide in a dense cyme. B.M. 1017.—Doubtfully in cult. horticulturally in Amer.

N. Taylor.†

GUMS AND RESINS. Of the many thousands of vegetable substances falling under the denomination of gums and resins, but a comparatively small number are of such general importance as to warrant mention here. Their economic value depends upon the physical and chemical properties possessed by them and the abundance in which they are produced. A gum, in the ordinary use of the word, is a substance of a more or less sticky nature or which was at one time of a sticky or plastic consistency. The chemist, however, restricts the term gum to certain products having very definite properties, classifying other plant exudations according to their properties and grouping them as resins, gum resins, balsams, and the like. A gum in this restricted sense, is a substance which dissolves or softens in cold water, forming a mucilage, or at least a liquid of gelatinous consistency, and when held in a flame only chars with an odor of burnt sugar. It is insoluble in 60 per cent alcohol, oil of turpentine, benzene or fatty oils. A resin, on the other hand, is a lustrous vegetable substance resembling a gum but which neither dissolves nor softens in cold water and which burns with a bright smoky flame, giving off an aromatic odor. It is more or less soluble in alcohol, oil of turpentine, benzene or warm oils.

Gums are related, chemically, to cellulose and are not secretion products, as was formerly supposed, but are formed directly from the plant tissues by a breaking down of the cells themselves; sometimes this is a perfectly normal process but very often it may be considered pathological and is the result of bacterial action. Humidity appears to be the principal controlling factor in the production of gum. Volatile or essential oils are secreted by the cells of many plants of widely divergent relationships and are often characteristic of certain families, like those to which belong the mints and the pines. The resins are oxidation products derived from certain of the volatile oils and thus may indirectly be considered products of secretion. Some plants yield only gum, others only resin, while others again may yield both, in which case the gum and resin may come from different parts of the same plant or may be exuded as an emulsion or mixture. In many plants the resins occur dissolved in volatile oil and though exuded in a liquid state soon become solid through the evaporation of more or less of the volatile oil. Some resins contain aromatic acids and others consist of certain liquid organic compounds of these acids in which is dissolved a solid resin; such products are called balsams. The camphors constitute another group of oxidation products derived from the volatile oils.

Uses of gums and resins.

Soluble gums, the most typical of which is gum arabic, are used for a great number of purposes in the arts; the varieties having the least color, highest adhesive power and viscosity being the most valuable. They find application in confectionery and pharmacy, in sizing and finishing textile fabrics and paper, in calico printing and dyeing, and in the manufacture of fine water-colors, ink, mucilage, and so on. The gums which are more or less insoluble in water, but which swell with it to form a mucilage, as for example tragacanth, are used as thickening agents in calico-printing and in pharmacy, and for pastes, pills and colored crayons.

Resins are applied to a great variety of industrial purposes but probably the most important of these is the manufacture of varnishes and lacquers. For this purpose they may be roughly divided into two classes: (1) those which after melting can be combined with linseed oil and turpentine to form an "oil varnish," and (2) those which dissolve more or less in alcohol, oil of turpentine or other volatile solvents to form "spirit varnishes." The important resins of the first class are amber and the copals; while those of the second class include rosin or colophony, benzoin, dammar, sandarac, mastic and elemi. Aside from varnish-making, certain resins are employed in medicine and pharmacy, for incense, and in the manufacture of soap, and the like.

The gums and resins of greatest economic importance.

The following list of the plant exudations which are of the greatest economic importance and which comprises one or more typical examples of each of the groups already mentioned may be arranged as follows:

- **True gums**
  - Gum arabic
  - Tragacanth
- **True resins**
  - Amber
  - Copal
  - Dammar
  - Sandarac
  - Mastic
  - Rosin
- **Balsams**
  - Balsam Peru
  - Storax
- **Gum-resins**
  - Gamboge
  - Myrrh
  - Olibanum
  - Galbanum
- **Oleo-resins**
  - Turpentine
  - Canada balsam
  - Copaiba
  - Elemi
- **Camphors**
  - Camphor (Common or Laurel Camphor)
  - Menthol

Gum arabic.—The name still generally applied to the most important gum produced in northern Africa and which has been an article of commerce since the first century of the Christian era. It was shipped from Egypt to Arabia and then thence to Europe and was therefore called "gum arabic." At present the gum is usually known as "Sudan," "Kordofan" or "Senegal" gum, depending upon the region from whence it is shipped to market. The best gum is produced by the gray-barked acacia tree, *Acacia Senegal*, and is collected both from wild or unowned trees and from gardens of acacia trees which are private property. In the gardens the gum is obtained by making incisions in the principal branches of the trees while from the wild trees the naturally exuded gum is collected. Inferior varieties are collected from *Acacia Seyal*, chiefly from the forests of the Blue Nile, and from *Acacia arabica*, *A. stenocarpa* and *A. albida* in Senegal. The gum is cleaned from pieces of bark and other debris before leaving Africa but the bulk of the product is exported without grading and is sorted in Europe, principally at Trieste and Bordeaux.

Tragacanth.—The most important of the so-called insoluble gums, and the only one regularly found in commerce, is obtained from several species of small shrubs of the genus Astragalus, found in Asia Minor, Syria, Armenia, Kurdistan and Persia. It is produced chiefly by the following species: *Astragalus adscendens*, *A. gummifer*, *A. pycnocladus*, *A. kurdicus* and *A. stromatodes*. In order to obtain the greatest quantity of gum, the shrubs are stripped of their leaves in July or August and short incisions or slits are made in the trunks. The gum flows out, forming flat ribbon-like or vermiform pieces depending upon the shape and size of the incision, and is dry enough for gathering in three or four days. Smyrna is an important market for gum tragacanth and it is there sorted into various qualities for the European market.

Amber.—A fossil resin found principally on the shores of the Baltic Sea. The larger and finer pieces are used for jewelry, beads, trinkets, mouthpieces for pipes and cigar-holders, while the smaller pieces and the waste from carving or turning are used for varnish.

Copals.—The term "copal" is now used commercially to designate a group of widely distributed hard resins of high melting point having the common property of being capable of being used for the manufacture of oil varnishes. Aside from amber, Zanzibar, or true copal was the first resin used for this purpose, hence arose the custom of terming as "copal," each new resin which was discovered to be useful for this purpose and distinguishing it from others by prefixing its port of shipment or other geographical name. Copals are obtained in round tears, nodules or flat pieces of varying degrees of hardness, either from living trees (recent or raw copals) or dug from the earth at spots, occupied centuries before by trees long since disappeared (fossil or ripe copals). The most important are yielded by the following plants: Zanzibar copal, *Hymenæa Hornemanniana;* Sierra Leone copal, *Copaifera Guibourtiana;* Gold Coast or Accra copal, *Cyanothyrsus Ogea;* Niger copal, *Daniella oblonga;* Kauri copal, *Agathis* (*Dammara*) *australis;* Manila or East Indian copal, *Agathis* (*Dammara*) *orientalis;* West Indian or Demerara copal, *Hymenæa Courbaril.*

Dammar.—Dammar is the Malay term for all gums and resins which exude from trees and solidify upon exposure to the air, but as used commercially it designates a group of varnish resins obtained from Indian or East Indian trees belonging to the *Dipterocarpaceæ* and *Burseraceæ* and thus does not include the resins from the genus *Agathis* (or *Dammara*,) which are known as copals. Indian dammar, *Shorea robusta;* white dammar, *Vateria indica;* black dammar, *Canarium strictum;* rock dammar, *Hopea odorata.*

Sandarac.—The hard brittle resins produced by several species of coniferous trees in North Africa and Australia. Mogadore sandarac, yielded by a small cypress, *Thuya articulata*, common on the southern slopes of the Atlas Mountains, is shipped principally from the port of Mogadore, Morocco. Australian sandarac is the product of several species of cypress pines, especially the Murray pine, *Callitris verrucosa* and the red or black pine, *Callitris calcarata.*

Mastic.—A soft yellow resin obtained in brittle, yellowish, glassy, rounded drops from *Pistacia lentiscus*, a small tree indigenous to Asia Minor and the Greek Archipelago but cultivated on the island of Chios. Used for varnishing paintings, for incense and as a tooth cement.

Common rosin or colophony.—This is the solid residue obtained as a by-product in the distillation of oil of turpentine from crude turpentine. For a list of the most important sources, see *Turpentine*, below. Rosin is used for cheap furniture varnishes, in the sizing of paper, as a flux for solder, as a coating for the inside of casks, and in the manufacture of laundry-soap. It is the source for rosin-oil and rosin-spirit, which are produced by the destructive distillation of rosin. The first is used in the production of lubricants, printing inks and paints, while the second is a substitute for oil of turpentine.

Gamboge.—A hard brittle yellow gum-resin, composed of a variable mixture of gum and resin, and produced by several species of Garcinia, especially *G. Hanburyi* of Siam and Indo-China and *G. Morella* of India and Ceylon. It is used to color golden lacquers, as a water-color pigment and in medicine as a drastic purgative.

Myrrh.—A fragrant gum-resin obtained in Arabia and northeastern Africa from a burseraceous tree *Balsamodendron Myrrha.* It is used in medicine and for dental preparations.

Olibanum or frankincense.—A fragrant gum-resin obtained from the stem of several species of Boswellia, especially *B. Carterii*, native to northeastern Africa and the southern coast of Arabia. Its principal use is for the incense used in the Roman Catholic and Greek churches.

Galbanum.—A strong-smelling, yellowish brown gum-resin exuded from the stem of certain species of Ferula, especially *F. galbaniflua* and *F. rubricaulis*, natives of Persia. It is mentioned by the earliest writers on medicine and was an ingredient of the incense used in the worship of the ancient Israelites. It is now used only to a small extent in medicine.

Turpentine.—The crude oleo-resin obtained by tapping any one of several species of coniferous trees native to North America, Europe and northern Asia. The most important varieties are yielded by the following species: American turpentine from the long-leaf pine, *Pinus palustris*, and the Cuban pine, *Pinus heterophylla;* French turpentine from the maritime or cluster pine, *Pinus maritima;* Russian turpentine from the Scotch or Swedish pine, *Pinus sylvestris;* and Indian turpentine from the Indian blue pine, *Pinus excelsa*, the Himalayan long-leaf pine, *Pinus longifolia* and the Burma pine, *Pinus khasya.* From these oleo-resins there is distilled oil of turpentine, leaving behind rosin or colophony. Venice turpentine, from the common larch, *Larix europæa*, is about the consistency of clear honey, and is used in fixing colors, enamel painting and firing and in medicine.

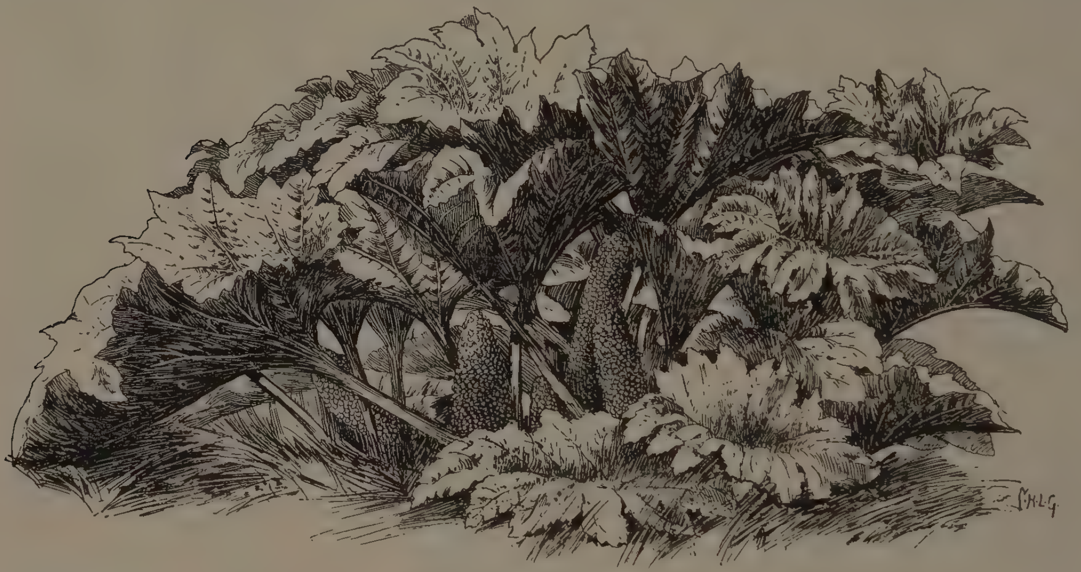
Canada balsam.—A thick, yellow, transparent, liquid oleo-resin obtained in the northern United States and Canada from the balsam fir, *Abies balsamea.* On account of its great capacity for refracting light it is used to cement lenses and for mounting objects for the microscope. It is also used in medicine.

Copaiba balsam.—A thick, transparent, brownish, liquid oleo-resin obtained from several species of leguminous trees belonging to the genus Copaifera and native to northern South America. It is used in medicine as an antiseptic and stimulant.

Elemi.—More or less soft resins yielded by burseraceous trees belonging to the genera Protium and Canarium. Manila elemi from *Canarium luzonicum* is a fragrant resin used for toughening varnishes.

Balsam Peru.—A dark brown molasses-like liquid balsam obtained in Salvador and Guatemala from the stem of a leguminous tree, *Myroxylon Pereiræ.* It is used in medicine, perfumery and chocolate manufacture.

Styrax or storax.—A thick, grayish, sticky, liquid balsam obtained in Asia Minor from the oriental sweet gum, *Liquidambar orientalis.* It is used in perfumery, pharmacy and in medicine.



1770. Gunnera manicata.

Common or laurel camphor.—A white, crystalline, pungent substance obtained by distilling with steam the twigs and chips of the camphor tree, *Cinnamomum Camphora,* native to China and Japan and cultivated in the southern United States. It is used in medicine and for the manufacture of celluloid, lacquers and smokeless powders.

Menthol or peppermint camphor.—The principal constituent of oil of peppermint, the essential oil of *Mentha piperita,* from which it can be crystallized by chilling. It resembles common camphor but has a strong peppermint odor. Used in medicine and perfumery.

Frederick L. Lewton.

GUM-TREE: *Eucalyptus* and *Acacia;* also *Liquidambar.*

GUNNÈRA (J. Ernst Gunner, 1718–1773, was a Swedish bishop and botanist, and wrote a local flora). *Haloragidàceæ.* Perennial herbs, some of them big-leaved and used for subtropical effects; others small and useful for bogs and rockeries.

The family Haloragidaceæ comprises above 100 widely scattered and heterogeneous species in 8 genera. In the northeastern states are the aquatic genera, Proserpinaca, Hippuris, Myriophyllum. These comprise small and mostly inconspicuous water- or bog-plants. In the Australian region are the endemic genera, Loudonia and Meionectes; and there remain Serpicula, Gunnera, and Haloragis, with very wide and disjointed distributions. Gunnera has 25 or more known species in S. Afr., Abyssinia, Java, Tasmania, New Zeal., Hawaii and S. Amer. In general appearance the gunneras are wholly unlike our native haloragaceous plants. The lvs. are radical, ovate or orbicular, in certain species gigantic: fls. perfect or rarely imperfect monœcious or polygamous, small, in simple or branched spikes or panicles, often packed on a great cob-like spike; petals 2–3, or none; calyx none, or with 2–3 lobes; stamens 1 or 2 or 3; ovary 1-loculed, bearing 2 filiform styles: fr. a drupe: plant rhizomatous.

Gunneras are striking herbs, and with protection the two first species may be grown even in some of our northern states. These two are amongst the noblest of lawn foliage plants. To produce satisfactory effects, rich moist ground is indispensable. The plants must never suffer for want of water. Exposure to sun is advisable, but they should be sheltered from severe winds, else the leaves will be damaged. Ample winter protection should be provided. A liberal covering of leaves or litter, held in place by brush or branches, will generally keep them from harm. Apply the covering in December and remove early in spring. Propagate by division. Seeds are also employed, and they can usually be secured.

A. *Lvs. very large and striking.*

manicàta, Lind. Fig. 1770. St. thick and very short, the titanic crown of lvs. rising from the ground: petioles often as tall as a man, prickly: blades becoming 5–10 ft. across, orbicular in general outline, variously lobed, crenate, furrowed and channeled along the great veins: fls. green: spikes dense and tapering, often more than 1 ft. diam. and 3–4 ft. tall. S. Brazil. I.H. 31:531. Gn. 45, p. 21; 50, p. 455; 54, p. 385; 59, p. 327; 63, p. 127; 70, p. 179; 74, p. 451. G.C. III. 14:589; 29, suppl. Jan. 12. G.M. 54:101, 647. G.F. 8:55.—The crown of lvs. sometimes measures 25–35 ft. across, making a magnificent plant. This is the better species.

chilénsis, Lam. (*G. scàbra,* Ruiz & Pav.). Not so robust, the lvs. smaller and less spiny, and the fl.-spikes less tall: fls. reddish. R.H. 1862, p. 310; 1894, p. 397.

Gn. 49, p. 151. G.C. II. 26:425; III. 8:665. G. 18:693; 21:661. G.W.5:367, 571; 12:413.—Thrives in drier soil. Var. **màjor,** Hort., is a very strong-growing form.

AA. *Lvs. of ordinary or even small size.*

arenària, Cheesem. Prostrate and creeping plant making extensive patches in damp sandy land in New Zeal., the rhizome stout and clothed with bases of old foliage: lvs. 2½ in. or less long, thick, only slightly hairy, the blade less than 1 in. and broadly ovate or oblong, crenate or somewhat lobed: male peduncles usually longer than lvs., and female much shorter at flowering time; female fls. densely crowded into a short oblong spike: drupes very small, fleshy, yellowish red.

dentàta, Kirk. More slender, forming extensive patches in wet subalpine places in New Zeal.: lvs. many and tufted, prominently hairy, the blade 1 in. or less long and varying from ovate to oblong and elliptic-lanceolate, coarsely dentate: male spikes about equaling the lvs., the female short and hidden at the base of the lvs., but the spikes in fr. sometimes surpassing the lvs.: drupes minute ($\frac{1}{10}$in. long).

magellánica, Lam. A very small species with dark green lvs.: stoloniferous: lvs. orbicular-reniform, crenate, 2½ in. or less broad: male scape surpassing the lvs., female shorter: fls. apetalous, the male pedicelled, the female sessile. Chile south, and Falkland Isls.

G. brephogèa, Lind. & André. A large species: lvs. tall-petiolate, the limb peltate, concave, orbicular-reniform, rather shallowly 7–9-lobed and the lobes again somewhat lobed or angled, the margin with many small acute inflexed teeth and black-purple: female fls. in a lax spike-like panicle, on a purplish scape. Colombia. I.H. 19:111.—*G. mínima,* Hort.=G. magellanica (?).—*G. perpénsa,* Linn. Lvs. long-petioled (12–18 in.), orbicular-reniform, cordate at base, 6–12 in. across, uniformly and closely crenate-toothed: scape surpassing the lvs., becoming 2–3 ft. high; fls. monœcious, the males in the upper part of the slender spikes. S. Afr. in moist places. B.M. 2376.

L. H. B.

GURÀNIA (Anagram of Anguria). *Cucurbitàceæ.* Tall climbers, perennial herbs or shrubs, with simple tendrils: lvs. entire, lobed, or 3–5-foliolate: fls. diœcious or rarely monœcious, small, bractless, the petals pale yellow; male fls. in long-peduncled clusters, the calyx-tube cylindrical or ventricose and the limb 5-parted, the corolla 5-parted into linear or triangular papillose thickened segms., the stamens 2 and free; female fls. solitary on fascicled or capitate on the top of the peduncle, staminodia none, ovary oblong and bearing a bifid style: fr. oblong, terete, many-seeded, the seeds ovate and compressed. There are about 50 guranias in the American tropics, one of which, *G. malacophýlla,* Rodr. (*G. eriántha,* André, not Cogn.), has recently been mentioned in horticultural literature abroad. This is a strong villous climber with simple broadly ovate sometimes 3- to 5-lobed lvs. 4–8 in. long: male fls. reddish, in a globose head on a peduncle 6–16 in. long; petals linear-subulate, pubescent; female fls. not described. Upper Amazon. B.M. 8085. R.H. 1904:388.

L. H. B.

GUSTÀVIA (Gustavus III, King of Sweden). *Lecythidàceæ.* Trees and shrubs of the American tropics with large showy fls., of which **G. speciòsa,** HBK., is offered in S. Calif. It is a thick-lvd. tree with 6-petaled white fls., suitable for planting in the open. For fuller account, see *Japarandiba.*

GUTHNÍCKIA. Two plants now referred to Achimenes, one of which, *A. foliosa,* is perhaps sometimes cult. (See Vol. I, p. 208.)

GUTIERRÈZIA (personal name). *Compósitæ.* Herbs or subshrubs, often resinous, mostly western North American, rarely planted in borders.

Much branched from the base, and have narrow alternate entire lvs. and clusters of small yellow heads with flat receptacles and hairy achenes.—About 18 species. Easily cult. in Calif.; doubtfully hardy on Atlantic coast north of Washington.

Euthàmiæ, Torr. & Gray. More or less woody at base, seldom to 1½ ft. high: lvs. linear, crowded: involucre turbinate, 2 lines long; rays and disk-fls. each 3–9: achenes silky-pubescent; pappus of about 9 chaffy scales. W. N. Amer.

N. Taylor.†

GUZMÀNIA (A. Guzmann, Spanish naturalist). *Bromeliàceæ.* Includes *Caraguàta* and *Massángea.* Tropical American bromeliads, of which several are fairly well known ornamental glasshouse subjects.

They closely resemble the erect-growing tillandsias, but differ in technical characters: fls. in a simple spike-like terminal cluster, tubular, the outer segms. or calyx oblong and obtuse, the inner or petals shorter than the tube; anthers inserted on the throat of the tube, and united by their edges around the style.—About 75 species. Grown in the warmhouse, along with Billbergia and Tillandsia, which see for culture. Closely allied to Æchmea. Many species are cult. in fanciers' collections in the Old World. For *G. picta,* see *Nidularium.* For *G. Legrelliana,* see *Hohenbergia. G. rosea,* a name which has appeared in the American trade, is probably an Æchmea.

A. *Calyx corolla-like, exceeding the petals.*

musàica, Mez. Lvs. strongly decurved, beautifully and densely marked with undulating, interrupted, irregular brown lines: infl. 3–4 in. long, on a short peduncle, the bracts golden, striped with rose; fls. 1⅔–2 in. long. Colombia. B.M. 6675. I.H. 24:268.

AA. *Calyx not corolla-like, shorter than petals.*

B. *Corolla (or segms.) purple or red.*

lingulàta, Mez (*Caraguàta lingulàta,* Lindl. *C. spléndens,* Bouché. *C. lingulàta spléndens,* Hort.). Epiphyte: lvs. many, lanceolate or ensiform, 1½ ft. long, remotely toothed: spike becoming drooping, showily red-bracted; expanded fl. about as long as the long-pointed bracts, the tube yellowish and the limb blue-purple. W. Indies, Cent. Amer., and S. Amer. B.R. 1068. F.S. 11:1091.—Handsome. Var. **cardinàlis,** André (*Caraguàta cardinàlis,* André). Bright scarlet: very showy. Colombia. I.H. 27:374. R.H. 1883:12.

BB. *Corolla (or segms.) white.*

trícolor, Ruiz & Pav. (*G. fràgrans,* Hort., at least in part. *G. grándis,* Hort., in part. *G. maculàta,* Hort., in part. *G. monostàchya,* Rusby). Lvs. several to many, broad and more or less recurved, entire on the edges, usually shorter than the stout, erect spike: lower bracts green streaked with black, upper ones red-tinged: corolla white. W. Indies, Cent. Amer., S. Amer. L.B.C. 5:462. F.S. 9:918. B.M. 5220. Var. **variegàta,** Hort. Lvs. striped with white. S. Fla.—Interesting because of its combination of green, red and white. Some, at least, of the horticultural plants which pass as *G. fragrans* belong to *Æchmea eburnea,* Baker (*Canistrum Lindenii,* Mez. *Nidularium Lindenii,* Regel). This species is further mentioned under *Nidularium.*

Devansayàna, Morr. (*Caraguàta Devansayàna,* Morr.). Lvs. about 20, narrow linear or ensiform, brown-striped on the back: fls. white, in a dense, oblong spike, the scarlet bracts oval. Ecuador.

BBB. *Corolla (or segms.) yellow.*

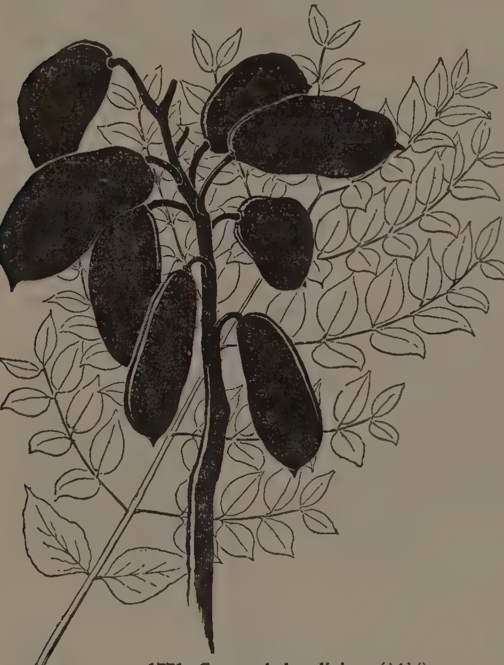
Melinònis, Regel (*Caraguàta Melinònis,* Morr.). Lvs. strap-shaped, green above and brown-tinted beneath: fls. yellow, subtended by oblong red bracts. French Guiana.

George V. Nash.†

GYMNÓCLADUS (from Greek *naked,* plus a branch, which refers to the stout branches with few branchlets). *Leguminòsæ.* Trees, useful for bold planting.

Flowers diœcious or polygamous, regular, not papilionaceous; calyx tubular, 5-cleft; petals 5, oblong, perigynous, resembling the sepals, or slightly larger and paler; stamens 10; filaments pubescent, distinct, short, perigynous; pistil 1; ovary superior, simple, 1-celled; placenta parietal; ovules numerous; style slender: fr. an oblong (2–10-in. long), thick, flat, curved, dark brown legume; seeds lenticular, about 1 in. broad.—The genus contains 2 species, one American, the other E. Asian. The American species, the Kentucky coffee tree, is now frequently planted for ornamental purposes. Its ascending branches, coarse twigs and pods give it a peculiar sturdy aspect, heightened in summer by the immense compound lvs. Prop. by seeds and cuttings. Foliage appears in late spring.

dioìca, Koch (*G. canadénsis*, Lam.). Kentucky Coffee Tree. Fig. 1771. Tree up to 100 ft. high, unarmed: lvs. alternate, unequally twice-pinnate, 1½–3 ft. long; lfts. ovate or oval, acuminate, stalked, entire, glabrous, 1–3 in. long: fls. ½in. long, greenish white, in large panicles, which terminate the branches of the same season: pods persistent through the winter. Rich woods, Cent. N. Y., and Pa. to Minn., Neb., Okla., and Tenn. S. S. 3:123, 124. R.H. 1897, p. 491. B.B 2:261. G. 6:215.—Seeds used for coffee west of the Alleghanies before and during the Revolutionary war.



1771. Gymnocladus dioica. (×⅛)

G. chinénsis, Baill., with smaller more numerous lfts. and much thicker pods, is not cult.

K. M. Wiegand.

GYMNOGRÁMMA. Ferns that belong in several genera, to which they are here referred. The ferns described under Gymnogramma in previous editions are distributed in the present edition as follows:

For *Gymnogramma hispida*, see *Gymnopteris;* for *G. triangularis*, *G. chrysophylla*, *G. sulphurea*, *G. decomposita*, *G. calomelanos*, *G. peruviana*, *G. tatarica*, *G. pulchella*, see *Ceropteris;* for *G. aurea*, see *Ceropteris argentea;* for *G. schizophylla*, see *Anogramma*.

R. C. Benedict.

GYMNOLÒMIA (*naked border*, because the pappus is minute or none). *Compósitæ.* About 20 yellow-fld. herbs or woody plants from Ga. to Mex., much like small-fld. helianthus. Lvs. alternate or opposite on erect branching sts.: fl.-heads on peduncles terminating the branches; involucre hemispherical or bell-shaped, with narrow bracts in 2 or 3 series; receptacle chaffy, more or less conical; ray-fls. pistillate and sterile; disk-fls. perfect, producing 4-angled achenes. Allied to Viguiera, and distinguished by the obsolete or wanting pappus. Probably none of the species is in cult. *G. Pórteri*, Gray, occurs on Stone Mt., Ga.: 1–2 ft. high, slender, with 5–8 oval or obovate rays ½in. or more long, deep orange-yellow. The other species are of the Texano-Mex. region.

L. H. B.

GYMNOPÉTALUM (Greek, *naked petal*). *Cucurbitàceæ.* Six species of tendril-bearing vines of tropical Asia and Java, of which one, *G. cochinchinense*, is cultivated chiefly for its ornamental gourds.

This species is a tender perennial plant, and is said to have small white fls. borne in late summer and autumn, as advertised in the seed catalogues, under the name of *Scotanthus tubiflorus*. Scotanthus was formerly thought to be a closely allied genus, differing in the staminate fls. possessing bracts and 3 bristle-like rudiments of an ovary, while the staminate fls. of Gymnopetalum, by the old definition, have no bracts or minute ones, and but 1 rudiment of an ovary. Coigneaux includes Scotanthus in Gymnopetalum.

cochinchinénse, Kurz (*Scotánthus tubiflòrus*, Naudin). Musk-scented: st. much-branched, slender, grooved, creeping or climbing, 5–7½ ft. long: tendrils filiform, elongated, simple: lvs. about 1½–2½ in. long, 1–2 in. wide: fls. monœcious, white; calyx-teeth long linear-awl-shaped; calyx shortly villous, not tomentose: lvs. ovate, angled or slightly lobed: fr. bright red, ovoid, 10-ribbed, rather acute at the base, produced at the apex into a long point which withers and remains, 2 in. long, more than 1 in. thick.

L. H. B.

GYMNÓPSIS: *Sclerocarpus.*

GYMNÓPTERIS (Greek, *naked fern*). *Polypodiàceæ.* A group of small tropical ferns with once-pinnate hairy lvs. with the sporangia forming long lines along the veins without indusia; the lf.-margins not rolled over as in Cheilanthes, and to which the genus is related.

híspida, Underw. (*Gymnográmma híspida*, Mett.). A low plant, 5–8 in. high, with pentagonal, palmate lvs. 1 in. or more either way, densely covered on both sides, but especially below, with strigose hairs. Has been incorrectly referred to *Gymnogramma Ehrenbergiana*. Texas, Ariz., Mex.—Hardy.

R. C. Benedict.

GYMNOSPÒRIA (*gymnos*, naked and *sporos*, seed; the seed being sometimes without aril). *Celastràceæ.* A genus of about 60 species widely distributed through Trop. and Subtrop. Afr., Asia and Austral., S. Eu. and Subtrop. S. Amer. Closely related to Celastrus, but easily distinguished by their habit, being rigid, often spiny shrubs or small trees with coriaceous rather small lvs. and perfect small whitish fls. in axillary cymes followed by small capsular dehiscent frs.; seeds with or without aril. None of the species is hardy N.; *G. variabilis* being probably the hardiest. They are of little or no ornamental value and only occasionally and rarely cult. in botanical collections. Except *G. serrata* which is cult. in S. Calif., and recommended as a suitable shrub for evergreen hedges. Prop. by seeds and probably by cuttings.

serràta, Loes. (*Celástrus serràtus*, Hochst.). Evergreen shrub; the branches with slender spines or unarmed, puberulous or nearly glabrous at the extremities: lvs. coriaceous, short-petioled, ovate or elliptic to oblanceolate, obtuse, serrulate, glabrous, reticulate beneath, 1½–3 in. long: cymes small on axillary, forked, puberulous peduncles much shorter than the lvs.: caps. 3-valved, smooth. Abyssinia. **G. buxifòlia,** Szyszylowicz (*Celástrus buxifòlius*, Linn.). Usually spiny, several feet high: lvs. obovate, obtuse, crenately serrate, 1–2 in. long:

cymes dense, short-peduncled. Afr. B.M. 2070 (as *Celastrus cymosus*) and 2114 (as *C. buxifolius inermis*). **G. variábilis,** Loes. Lvs. oblong to oblong-lanceolate, acute, serrulate, 2–3½ in. long: cymes slender, much shorter than lvs.: caps. ½–¾in. across. Cent. China.

Alfred Rehder.

GYMNÓSTACHYS (Greek, *naked spike*, the scape being leafless). *Aràceæ.* One interesting tuberous-rooted herb with grass-like radical lvs., from Queensland and New S. Wales, sometimes grown in choice greenhouse collections, *G. ánceps*, R. Br. Scape 1 to nearly 3 feet tall, flattened, slender: spikes 1–3 in. long, slender and curved or drooping, in small clusters near the apex, with a leafy bract subtending each cluster; fls. small and sessile; perianth-segms. 4, obovate and not exceeding the ovary; stamens 4: fr. a berry ⅛ or ¼in. long.

L. H. B.

GYMNOSTÀCHYUM (*naked spike*). *Acanthàceæ.* Some of the plants of this name are Fittonias (which see). *G. ceylánicum*, Arn. & Nees, is by Lindau (Engler & Prantl Pflanzenfamilien) referred to Cryptophragmium, becoming *C. ceylanicum*, O. Kuntze, but by Bentham & Hooker is retained in the former genus. It is an erect herb from Ceylon, suitable for growing in the hothouse for its white-marked lvs. and small whitish fls. in clusters: lvs. opposite, oval or obovate, obtuse, somewhat serrate. B.M. 4706. J.F. 4:405. L. H. B.

GYMNÒTHRIX: *Pennisetum.*

GYNANDRÓPSIS (Greek words: the stamens look as if they were borne on the ovary). *Capparidàceæ.* Annual herbs grown out-of-doors.

This genus includes a tender plant with 5–7 lfts., and fls. resembling the spider flower, or Cleome. It is known to the trade at present as a Cleome, but Gynandropsis is distinguished by having a long torus (or receptacle), which is produced into a slender body (or gynophore) which is elongated at the middle, and bears the pistil to which the filaments are united. Cleome has a short torus, which often has an appendix on the back: stamens about 6 in Gynandropsis: in Cleome 4–6, often 10: lfts. 3–7: fls. white or purplish; sepals deciduous; petals entire or crenulate, obovate, with a slender claw: fr. a silique, usually inclosed within the calyx; seeds kidney-shaped or orbicular, compressed, with a wrinkled or tubercled coat.—The species of Gynandropsis are perhaps a dozen, in the warmer parts of the world. Pedicellaria is an older name for the genus, but it is not accepted by the "nomina conservanda" of the Vienna code. For cult., see *Cleome.*

speciòsa, DC. (*Cleòme speciòsa*, HBK.). Stiff annual, or perhaps a perennial, usually about 2 ft. and rather velvety toward the top: lfts. 5–7, subserrulate, oblong, acuminate: fls. violet, showy. Mex.

Wilhelm Miller.
N. Taylor.†

GYNÈRIUM (Greek, *gune*, woman, and *erion*, wool). *Gramíneæ.* Very large perennial grasses with broad, sword-like blades and plume-like diœcious inflorescence.

Spikelets 2-fld., the florets equal, the rachilla not produced beyond the upper floret; glumes of staminate spikelets equal, of the pistillate spikelets unequal, the upper twice as long as the lower; culms perennial, with extensively creeping rhizomes, the plants growing gregariously in large masses or areas in their native habitat: lvs. rather evenly distributed along the sts., the sheaths about equal, the blades as much as 3 in. wide.—One species in Trop. Amer. Cortaderia of Stapf differs in the 3–6-fld. spikelets, the upper florets more or less reduced, in the equal glumes in both sexes, in the biennial culms with only very short rhizomes, the plants thus growing in large tussocks; in the lvs., scarcely ½in. wide, being crowded at the base of the plant, the sheaths increasing in length from base upward. The difference in appearance between the staminate and pistillate plumes is much more marked in Gynerium than in Cortaderia.

saccharoìdes, Humb. & Bonpl. Uva-Grass. Culms perennial, as much as 40 ft. high: on the sterile shoots the lvs. are aggregated, fan-like at the summit; on the fertile sts. they are scattered along the middle, the basal and upper portions being naked: plume white or tawny. B.M. 7352.—Cult. for ornament, the plumes resembling those of pampas grass. Not hardy outside the tropics. For pampas grasses see *Cortaderia* and *Pampas-Grass.*

A. S. Hitchcock.

GYNÓPOGON (Greek, *bearded stigma*). *Apocynàceæ.* Syn. *Alýxia.* Interesting tropical woody plants, worth cultivating under glass.

The genus was established in 1776 by Forster, based upon *G. stellatus* of Tahiti, and is now known to include at least 50 species distributed in the islands of the Pacific, Madagascar, Austral. and Trop. Asia. Evergreen trees or shrubs, erect or twining, nearly all of which have the agreeable fragrance of coumarin, with entire, short-petioled, glossy, myrtle-like lvs., usually in whorls of 3 or 4, or sometimes opposite: fls. usually fragrant, axillary or terminal, solitary or in umbellate or spicate cymes; calyx 5- or 4-cleft; corolla salver-shaped, its tube cylindrical, swollen above the middle, or slightly contracted at the throat, without scales, the 5 or 4 lobes sinistrose; anthers subsessile, as many as the lobes of the corolla and alternate with them, inserted on the tube; ovary of 2 distinct carpels united by a single style with a capitate, or oblong stigma often bearing hairs on its upper surface; ovules 4–6 in each carpel in 2 series: fr. generally a single ovoid or oblong drupe, usually moniliform, consisting of 2 or more 1-seeded joints placed end to end, sometimes both carpels maturing in the same fl., when the fr. becomes geminate, as in many other Apocynaceæ; seeds ovoid or oblong, furrowed on the ventral side, remarkable for their ruminate endosperm with erect embryo, in which respect they differ from those of other Apocynaceæ and agree with Annonaceæ. Plants of this genus may be prop. by seeds or cuttings. They are worthy of cult. in the conservatory, on account of their dark green lustrous foliage and their fragrant jasmine-like fls.

olivæfórmis, Safford (*Alýxia olivæfórmis*, Gaud.). Maile. A straggling or somewhat twining shrub with opposite and ternate lvs., blades ovate to oblong, obtuse or acuminate at both ends, coriaceous glossy, with evanescent veins and margins usually revolute over an intramarginal nerve: peduncles axillary, 3- or 4-fld.; corolla yellowish, salver-shaped, the tube slightly dilated below the contracted throat, puberulous within along the adnate filaments, limb 4- or rarely 5-lobed: drupes often geminate, fleshy black, elliptic-oblong, sometimes curved, acuminate at each end. Hawaiian Isls., in the woods of the lower and middle regions.—This is perhaps the most cherished plant of the Hawaiians, who weave its fragrant glossy foliage into garlands, or leis, with which to adorn their friends, and with its branches decorate their houses and lanais on festive occasions; and they also celebrate its fragrance in their songs. Other allied species are the *laumaile* of Samoa (*Gynopogon bracteolosus*), the *nanago* or *Loduson lahe* of the island of Guam (*Gynopogon Torresianus*), and the *maire* of Tahiti (*Gynopogon stellatus*).

W. E. Safford.

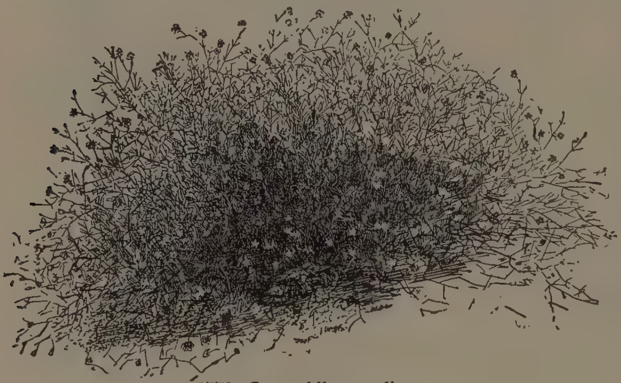
GYNÙRA (name refers to the tailed stigmas). *Compósitæ.* Tropical herbs, sometimes grown under glass for the large showy foliage.

Rarely subshrubby: lvs. alternate, entire or lobed, numerous: heads discoid, the florets commonly all fertile, not very showy; involucre cylindrical or somewhat bell-shaped, the narrow bracts in about 1 series: achene narrow, 5–10-striate, with copious slender white pappus-bristles. The gynuras are attractive glasshouse herbs, usually requiring a moderately high temperature; prop. by cuttings. Genus allied to Senecio and Cineraria; of about 40 species in Trop. Afr., Asia, to Austral.

aurantìaca, DC. VELVET TREE. Stout and branchy, 2–3 ft., with almost succulent sts. densely clothed with violet or purple hairs: lvs. large and soft, ovate, jagged-toothed, hairy, short-petioled or the upper ones clasping, overlaid with iridescent purple: heads in a terminal cluster, yellow or orange. Java. I.H. 28:436.—A handsome foliage plant. In winter it may be grown in the conservatory or warmhouse, but in the summer it may be bedded out in a warm and protected place. It grows rapidly, and makes a most satisfactory display of colored leafage. It is readily prop. by cuttings in the house, as geraniums are.

Other species, but not known to be in the American trade, are: *G. auriculàta*, Cass. (G. ovalis, DC. Cacalia ovalis, Ker). Only slightly villous: lvs. oval, entire or repand, green both sides: fls. yellow, fragrant. China. B.R. 101.—*G. bícolor*, DC. 2–3 ft., of looser growth than the above, glabrous: lvs. lance-ovate, somewhat downy, short-petioled, deep-toothed or pinnatifid, green above and purple beneath: fls. orange. Moluccas. B.M. 5123.—*G. ovàlis*, DC.=G. auriculata.—*G. sarmentòsa*, DC. Climbing, with purple glabrous sts.: lvs. narrow, ovate to lanceolate, acuminate, petioled, remotely small-toothed, green and purple-ribbed. Warmhouse plant from Malayan Isls. B.M. 7244.

L. H. B.



1772. Gypsophila muralis.

GYPSÓPHILA (*gypsum-loving*, because it likes calcareous soils). *Caryophyllàceæ.* European and Asian herbs, bearing a profusion of small flowers, and useful for mist-like effects in mixed borders and as trimming in bouquets.

Sepals 5, united below, but the calyx naked at the base (not bracted, as in some related genera) 5-nerved; petals 5, clawed, very small, usually white, in some horticultural forms pinkish; stamens 10; styles 2: pod 4-valved: lvs. small, entire, opposite.—Perhaps 75 species. Very branchy or spreading, slender herbs, with scant foliage when in bloom. Of easiest cult. in open, rather dry places. They are desirable for rockwork. They make an excellent effect as filling amongst shrubbery; also good for covering unkempt places with a mass of delicate bloom. Hardy.

A. *Plant annual.*

muràlis, Linn. Fig. 1772. One to 1½ ft., very diffuse and branchy, mostly with shorter joints than *G. elegans*, of finer appearance, the st. rough-hairy near the base, smooth above: lvs. linear, spurry-like: fls. small, rosy, the petals almost recurved, crenate. Eu.—Makes a dense little mound when well grown.

élegans, Bieb. Fig. 1773. One foot, repeatedly forked-branched, glabrous: lvs. sessile, the uppermost linear, the lower oblong or spatulate: fls. white or sometimes (*G. ròsea*, Hort., and in rare wild forms) rosy; petals truncate, almost recurved, 2–5 times as long as the calyx. Caucasus.—Much cult., and handsome.

AA. *Plant perennial.*

B. *Lvs. short, spatulate: plant pubescent.*

cerastioìdes, D. Don. Low, densely pubescent: lvs. pubescent, the radical ones long-petioled, the others spatulate or obovate, obtuse or nearly so: fls. large (often ⅖in. across), white or lilac, pink-veined. Himalayas. B.M. 6699. Gn. 47, p. 422. G. 35:433.—Of creeping habit; excellent for rockwork.

BB. *Lvs. perfoliate.*

perfoliàta, Linn. (*G. scorzonerifòlia*, Hort.). A tall, thick and round-stemmed perennial, usually glabrous, but sometimes hairy near the summit: lvs. perfoliate, 5-nerved: fls. purplish, the sepals only slightly shorter than the petals. Medit. region.

1773. Gypsophila elegans. (Natural size)

BBB. *Lvs. long, not perfoliate: plant glabrous or nearly so.*

paniculàta, Linn. BABY'S BREATH. Fig. 1774. Diffuse and rather tall-growing (2–3 ft.), forking: lvs. linear-lanceolate, the largest 3 in. long, but becoming smaller toward the infl., sharp-pointed: fls. white, very numerous; pedicels 2–3 times as long as the calyx. Eu. Gn. 68, p. 162.—A very popular plant, especially for use in the trimming of bouquets. A most graceful subject. Sts. stiff and wiry, therefore excellent for cutting. A picture of its use in floral arrangement will be found in A.F. 6:340. Var. **flòre-plèno,** Hort., with double fls. has been advertised, but is little known in Amer. Gn. 60, p. 103. A.F. 19:767. In places where the double form is difficult of cult., it is recommended that it be grafted on roots of *G. paniculata*.

acutifòlia, Fisch. Very like the last, but the plant greener, the lvs. narrower (indistinctly 3-nerved) and the pedicels scarcely longer than the calyx. Caucasus.—*G. paniculata* seems sometimes to be cult. under this name.

Stèvenii, Fisch. (*G. glaùca*, Hort.). Lower than *G. paniculata*, glaucous-green: lvs. linear-lanceolate and carinate, mostly radical: fls. rather larger, white, the panicles smaller than those of *G. paniculata;* petals shorter than the calyx. Caucasus.

rèpens, Linn. (*G. prostràta*, Hort., not of Linn.). Sts. trailing or prostrate, ascending at the ends, not glaucous: lvs. linear, sharp-pointed, glabrous: fls. rather large, white, the petals about twice longer than the sepals and the pedicels usually much longer. Alps and Pyrenees. B.M. 1448.—Best adapted to the rockery, and the mixed border; blooms from midsummer to autumn. Var. **monstròsa,** Hort., is larger but otherwise the same. Var. **ròsea,** Hort., has rose-colored fls. and is frequently sold as *G. prostrata rosea*, also as *G. carminea*, Hort., which does not seem to differ.

N. TAYLOR.†

1774. Gypsophila paniculata.

H

HABENÀRIA (Greek, *a rein* or *strap;* referring to the shape of parts of the flower). *Orchidàceæ,* tribe *Ophrýdeæ.* REIN ORCHIS. Terrestrial leafy herbs, sometimes grown in bog-gardens and naturalized in moist places.

Tubers usually undivided, rarely lobed: fls. in terminal racemes or spikes, rarely solitary; sepals subequal, free or cohering at base, erect or spreading; petals usually smaller, often 2-lobed; lip spreading or drooping, long- or short-spurred at base, its blade entire or 3–5-fid.; column very short, sessile; rostellum usually 1-toothed or lobed; glands naked; anther-cells parallel or divergent: caps. ovoid or oblong, erect. The lateral lobes are sometimes fringed, giving the fl. a graceful appearance.—Species about 400, very widely distributed in temperate and tropical regions.

Few species of Habenaria are of much horticultural importance, especially in this country. Some of the exotic kinds enjoy some favor as stove plants in England, while there are a number of hardy North American species which can be recommended for outdoor cultivation in boggy places. *H. Susannæ, H. carnea, H. militaris* and other East Indian species are best grown in a moderately warm house, needing good light and a fair amount of water. It is recommended to repot them after the resting season in a compost of peat, moss, loam and crock dust, with the tuber resting upon the crocked-up bottom of the pot and the growing point just beneath the soil. They should then be given a good supply of water until after flowering. These habenarias are much like bletia in their requirements. The most popular species at present seem to be *H. ciliaris, H. fimbriata* and *H. psycodes,* but these give a very imperfect conception of the beauties of the genus, although in the opinion of some persons, *H. ciliaris* is the showiest orchid in temperate North America. The native species are procurable through collectors and dealers in native plants: foreign species through Dutch bulb-growers; and *H. radiata* through dealers in Japanese plants.

1775. Habenaria carnea. (×¼)

A. *Fls. purple; lip 3-parted: sts. leafy.*

B. *Segms. of lip entire: bracts nearly equaling the fls.*

1. **conópsea,** Benth. (*Gymnadènia conópsea,* R. Br. *G. conópea,* French authors). DEADMAN'S FINGERS. Fls. violet-purple to flesh-colored, rarely white, fragrant, medium-sized; spur longer than ovary, sometimes twice as long. June, July. Eu., N. Asia. G.C. III. 51:68.—There is an *H. conopsea* of Reichenbach dating from 1854, whereas Bentham's dates only from 1880.

2. **odoratíssima,** Franch. (*Gymnadènia odoratíssima,* A. Rich.). Fls. intensely red-purple, aromatic, only half as large as in the preceding; spur shorter than ovary. May, June. Eu.

BB. *Segms. of lip toothed.*

3. **peramœ̀na,** Gray. Rather tall: fls. large and showy, violet-purple; middle segms. of lip 2-lobed. July, Aug. N. J. to Va. and Ill. B.B. 1:466.

BBB. *Segms. of lip deeply and copiously fringed.*

4. **fimbriàta,** R. Br. Fls. lilac, rarely white, fragrant; petals laterally toothed. Summer. New Bruns. to Mich. and mountains of N. C. A.G. 12:152. G.F. 10:483. B.B. 1:466.

5. **psycòdes,** Gray. Three feet or less high: fls. many, crowded, much smaller than in *G. fimbriata,* lilac, rarely white, fragrant. July, Aug. Newfoundland to Minn. and high mountains of N. C. B.B. 1:466.

AA. *Fls. pink throughout: lvs. all radical.*

6. **cárnea,** N. E. Br. Fig. 1775. Lvs. dull green, spotted with white: fls. few, loosely clustered, light pink, fading nearly white; lip large; spur over 2 in. long. Penang. G.C. III. 10:729; 34:323. Gn. 47:182. G.M. 36:642. O.R. 4:209; 9:297; 11:frontis.; 13:59. G. F. 4:487. J.H. III. 33:319; 49:299. R.B. 21, p. 44.—One of the most beautiful of the genus; apparently not in American trade. Var. **nivòsa,** Hort., white. Gn. 47:182.

AAA. *Fls. orange.*

B. *Color orange-yellow throughout.*

C. *Lip nearly or quite entire.*

7. **íntegra,** Spreng. Two ft. or less high, leafy: fls. small, crowded. July. N. J. to La., near the coast. B.B. 1:463.

CC. *Lip fringed or lacerate.*

8. **ciliàris,** R. Br. YELLOW FRINGED ORCHIS. Fig. 1776. Fls. crowded, brilliant orange; petals fringed at apex; spur about twice as long as lip; lip long-fringed. Aug. E. U. S. B.M. 1668. B.B. 1:464.—A striking species.

9. **cristàta,** R. Br. Smaller: fls. much smaller; petals merely toothed; spur little exceeding the lip. July. N. J. to La. near the coast. B.B. 1:464.

BB. *Color cinnabar-orange, the sepals red-spotted outside.*

10. **cinnabarìna,** Rolfe. Small: st. leafy: lip 3-lobed; spur straight, nearly equaling ovary. Madagascar.—Not in American trade.

AAAA. *Fls. with green sepals and petals; lip brilliantly colored.*

11. **militàris,** Reichb. f. (*H. pusílla,* Reichb. f.). Bluish glaucous: fls. numerous; lip scarlet, trifid, mid-

lobe bifid; spur long and very slender, greenish white. Cochin-China. R.H. 1888:396. J.H. III. 33:53. G.M. 36:436. O.R. 4:209; 9:297.—The author says of this fine plant: "No English soldier can boast a jacket of a deeper scarlet than the lip of our plant." Not in American trade.

12. **rhodocheìla,** Hance. Nearly related to *H. militaris,* but fls. fewer and subcorymbose: petals almost helmet-shaped; lip varying from deep rose-pink to cinnabar and madder; spur dull yellow. China. B.M. 7571.—Not in American trade.

AAAAA. *Fls. white to green or greenish yellow.*

B. *Color pure white.*

C. *Lip entire.*

13. **nívea,** Spreng. Lvs., except 1 or 2 lowest, bract-like: fls. numerous, loosely clustered, small; spur very slender. Summer. Del. to Ala. B.B. 1:462.

14. **leucóstachys,** Wats. Usually tall and stout: lvs. several: fls. many, rather large. Idaho to Ariz., Calif. and Ore. Mn. 6:81.—Nearly related to *H. dilatata,* but distinguished by its spur greatly exceeding the sepals.

CC. *Lip fringed.*

15. **blepharigló̀ttis,** Torr. Fls. much as in *H. ciliaris,* but somewhat smaller; petals fringed or slightly erose at apex; spur about 3 times as long as lip. July. Newfoundland to N. C. and Minn. B.B. 1:465. Mn. 8:113. —One of our finest natives.

CCC. *Lip 3-parted.*

16. **longecalcaràta,** A. Rich. Lvs. all radical: fls. 1–3, large, long-stalked; middle lobe of lip narrow, lateral ones broader, unevenly fringed; spur twice as long as ovary, with pedicel. July, Aug. India. B.M. 7228.—Not in American trade.

17. **Susánnæ,** R. Br. (*H. gigantèa,* Don). St. tall, stout, leafy: fls. 3–5, very large, fragrant; broad, fan-shaped side lobes of lip deeply fringed; midlobe tongue-shaped, entire; spur more than twice as long as ovary and pedicel. India, Malaya, China. B.M. 3374. G.C. III. 16:279. J.H. III. 29:226. O.R. 4:209; 9:297.—This and the preceding species are among the largest-fld. and showiest habenarias. They appear not to be in the North American trade.

BB. *Color partly or wholly green, or greenish yellow.*

C. *Lip deeply 3-lobed or 3-parted.*

D. *Petals cleft or parted into 2 lobes or segms.*

18. **Élwesii,** Hook. Erect, leafy: fls. few, large, greenish yellow; petals cleft almost to base into long, slender, sickle-shaped, hairy segms.; lip smooth, the segms. long and slender. India. B.M. 7478.—A remarkable species.

19. **Bonàtea,** Reichb. f. (*Bonàtea speciòsa,* Willd.). Stout, leafy: fls. rather large, light green and white; lobes of lip, especially central one, tubular toward base. S. Afr. G.C. III. 17:743.—Cult. like *Disa grandiflora,* in a cool greenhouse with plenty of air, in a mixture of fibrous peat and sphagnum with perfect drainage. Requires a liberal supply of water all the year round.

1776. Habenaria ciliaris, c. yellow fringed orchid. (×¼)

DD. *Petals not cleft or parted.*

E. *Spur sac-shaped; lobes of lip entire.*

20. **chlorántha,** Spreng. Lvs. clasping: fls. not exceeding bracts, greenish. Mascarene Isls.

EE. *Spur long and slender.*

F. *Middle lobe of lip entire, the others fringed.*

21. **radiàta,** Spreng. Petals exceeding sepals; spur greenish white, about equaling the ovary. Aug., Sept. Japan.

FF. *All lobes of lip deeply fringed.*

22. **leucophæ̀a,** Gray. Four ft. high or less: fls. large, whitish or greenish, fragrant; petals erose; spur exceeding ovary. July. N.Y. to Minn. and Ark. B.B. 1:465.

23. **lácera,** R. Br. Ragged Orchis. Smaller: fls. greenish yellow; spur not equaling ovary. June, July. Nova Scotia to Ga. and Mo. B.B. 1:465.

CC. *Lip merely toothed or slightly lobed; fls. inconspicuous.*

D. *Fls. much shorter than the conspicuous bracts; spur sac-shaped, short.*

24. **bracteàta,** R. Br. (*H. víridis,* Cham.). Fig. 1777. Fls. greenish; spur often white. Summer. N. E. U. S. to Brit. Col., Eu. B.B. 1:463.

DD. *Fls. nearly equaling or exceeding bracts; spur long and slender.*

E. *Lvs. 1–2 near base of st.*

25. **tridentàta,** Hook. Fls. greenish, loosely clustered; lip wide at apex, 3-toothed; spur incurved. July, Aug. Newfoundland to Minn., Fla. and La. A.G. 12:153. B.B. 1:463. Now known as **H. clavellàta,** Spreng.

EE. *Lvs. 3 or more.*

26. **viréscens,** Spreng. Leafy: fls. greenish; lip only slightly exceeding petals, with 2 lateral teeth and a nearly basal wart. July. Range of preceding. B.B. 1:464. The name is now **H. flàva,** Gray.

CCC. *Lip entire; fls. inconspicuous.*

D. *Large lvs. all basal.*

E. *Lf. solitary.*

27. **obtusàta,** Richards. Spike loosely fld.; fls. yellow-green; lip deflexed; spur about equaling lip. Summer. Across Canada, south to N. Y. and Colo. B.B. 1:461.

EE. *Lvs. 2.*

F. *Spur much exceeding ovary.*

28. **orbiculàta,** Torr. Lvs. orbicular, lying on the ground: fls. numerous, loosely clustered, greenish; lip white, obtuse. July, Aug. Across Canada and Minn. to mountains of N. C. B.B. 1:461. Gn.M. 4:14.

29. **bifòlia,** R. Br. Butterfly Orchis. Lvs. oblong: fls. white, with tips of spur and lip greenish, fragrant in the evening. May, June. Eu.

FF. *Spur about equaling ovary.*

30. **Hookeriàna,** Gray (*H. Hoòkeri,* Lindl.). Lvs. oval, obovate or orbicular: fls. greenish yellow; lip acute. Summer. Nova Scotia to N. J. and Iowa. B.B. 1:461.

DD. *Large lvs. several above the base.*

E. *Spike commonly dense.*

31. **hyperbòrea,** R. Br. Fls. greenish; petals, obtuse lip and slender spur all about equally long. Summer. N. U. S. to Nova Scotia and Alaska. B.B. 1:462.

32. **élegans,** Boland. Large lvs. all on lower part of st.: fls. numerous, small, greenish; sepals 1-nerved, all alike; spur filiform. Vancouver Isl. to Calif.

EE. *Spike commonly loose.*

F. *Spur short, sac-shaped.*

33. **grácilis,** Wats. Three feet high or less: spike long, many-fld.; fls. greenish; spur about equaling lip and sepals. Ore. and Wash.

FF. *Spur not sac-shaped.*

34. **unalaschcénsis,** Wats. Fls. white or greenish; sepals, petals and lip about equal; spur slender, barely to nearly twice longer than lip. Summer. Unalaska to Calif. and Utah.—Near *H. elegans*, but more slender, with a longer and more open spike. It is referred by some to the genus Herminium.

35. **dilatàta,** Gray. Fls. greenish white; lip widened or even auricled at base; spur about as long, incurved. Summer. Cooler parts of N. Amer. A.G. 12:153. B. B. 1:462.—More slender and narrower-leaved than *H. hyperborea.*

H. geniculàta, D. Don. Slender-growing: fls. white with green spur. Burma, Himalayas. —*H. iántha*, Hook. (Platanthera iantha, Wight). Deciduous, about 16 in. high: fls. shortly stalked, creamy white; lip large, rose-purple and white with crimson-purple dots and streaks; crest bright yellow. S. India. G.C. III. 54:300.—*H. Lúgardii*, Rolfe. Lvs. 2, basal: raceme many-fld.; fls. white, the stylodes green; sepals ovate, acute; petals divided into 2 slender lobes. Bechuanaland. B. M. 7798.—*H. Régnieri*. Garden hybrid of H. militaris and H. carnea.—*H. Roebelénii*. Rolfe. Similar to H. militaris but dwarfer: fls. vermilion-scarlet; lip broad, deeply cleft at the sides. Annam. O.R. 1913:39. —*H. triquètra*, Rolfe. Plant somewhat glaucous: racemes about 10-fld.; petals white; sepals light green. Burma.

1777. Habenaria bracteata. (×¼)

T. H. KEARNEY, JR.
GEORGE V. NASH.†

HABÉRLEA (after Karl C. Haberle, professor of botany at Pesth, who died in 1831). *Gesneriàceæ.* One dainty little hardy herbaceous perennial plant, which is tufted and bears in spring a few scapes 4 to 6 inches high, with two to five nodding, violet-colored, five-lobed, tubular flowers, each about 1 inch long and 1 inch across. Allied to Ramondia.

Haberlea has 4 included didynamous stamens and a bell-shaped calyx; the corolla has a conspicuous tube, which is thrust out of the calyx nearly ½in., and 5 lobes, 2 of which are much smaller than the others, while in Ramondia the fl. seems to be wheel-shaped, with 5 equal petals, because the corolla-tube is very short and inconspicuous and the lobes deeply cut. Haberlea was intro. to cult. about 1881 by Leichtlin, and few, if any, of our skilled amateurs know the plant. It is not advertised in Amer. Only 1 species is known, and it is found wild only in a few miles of a single valley in Thrace, where it abounds on the southern slope of the Balkans on shaded schistose rocks. Only 4 species of Gesneriaceæ are found wild in Eu., and 3 of them, are said to be confined each to one spot. The genus Ramondia has the same habit and is equally desirable For cult., see *Ramondia.*

rhodopénsis, Friv. Like a very small gloxinia, and clothed everywhere with soft, spreading hairs, except the corolla: lvs. 2–3 in. long, obovate- or ovate-oblong, obtuse, coarsely crenate, thick, leathery, few-nerved: calyx 5-cleft; corolla pale lilac. B.M. 6651. Gn. 67, p. 71. G.W. 15:428. R.H. 1906, p. 231.

WILHELM MILLER.

HABRÁNTHUS: *Hippeastrum.*

HABROTHÁMNUS: *Cestrum.*

HACKBERRY: *Celtis.*

HACKMATACK, or TAMARACK: *Larix americana.*

HACQUÈTIA (named after Balthasar Hacquet, 1740–1815, author of works on alpine plants). *Umbellíferæ.* Syn. *Dóndia, Dondísia.* A monotypic genus consisting of an herbaceous perennial cult. in the alpine garden and thriving in good stiff loam. Prop. by division in spring, before growth commences. The species is *H. Epipáctis*, DC. From 3–8 in. high: lvs. radical, palmate, deeply lobed: fls. polygamous, in umbels on short pedicels, yellow; involucre of 5–6 large, green lvs. which are much longer than the umbels. Eu. L.B.C. 19:1832. G.W. 14, p. 197.—Blooms in April and May.

HÆMÁNTHUS (*blood flower*). *Amaryllidàceæ.* BLOOD LILY. African bulbous plants, of which the greater part are natives of the Cape region; grown indoors.

Flowers showy, often numerous, in umbels; perianth straight and erect, with a short cylindrical tube; segms. longer than the tube, narrow, equal; stamens 6, inserted in the throat of the perianth, usually exserted, the anthers versatile; style filiform and erect, on a 3-loculed ovary: fr. berry-like, indehiscent. The fls. are red or white, on a solid scape, which is little, if any, longer than the cluster of root-lvs.; they lack the corona of many amaryllidaceous plants.—Probably above 60 species from S. and Trop. Afr.

Hæmanthuses, like most Cape bulbs, are summer- and autumn-flowering; or, when started indoors or in frames, blooming in spring or early summer. The flowers often precede the leaves. The foliage is usually large and luxuriant, and the scape is often handsomely colored. The flowers are sometimes as much as 2 inches across, and produced in great ball-like heads nearly or quite a foot through. Yet the species are essentially curiosities in this country. The culture given nerine suits them well. Their season of growth is usually not more than three or four months, and the remainder of the year they may be laid away in the pots. When growing, give plenty of rather weak liquid manure, keep in an intermediate or warm house, and when in bloom keep them somewhat cooler. Avoid overpotting.

They are increased by offsets, which should be detached from the parent plants in the spring. The bulbs may be potted singly, or several in a pot, in equal parts of peat and loam, with enough sand to make the compost have a gritty feeling when passed through the hands. Cover the lower half of the bulb with soil and pot them firmly. Leaf-mold may be used instead of peat, if that soil is not available. Hæmanthus will grow well in a night temperature of 50° to 55°. However, they are often grown 10° lower, but never with the same success. Water the plants carefully until they get into active growth, after which water may be applied more liberally. Syringe the plants on all bright days, morning and noon during their growing period. During the summer months, shade them slightly; and when they are in flower the shade may be much heavier. This is of great assistance in making them last longer. As soon as the plants show signs of going to rest, withhold water, letting the soil become quite dry. Start them into growth in the spring about the first of March. It is not necessary to pot these plants every year, as they flower much better if not disturbed much at the roots. If they are not repotted, water with weak liquid manure once a week, after they are growing vigorously. These plants are liable to attacks from green-fly and red-spider. Fumigation with tobacco, in any form generally used in greenhouses, will keep the former in check; and on bright days, a careful syringing of the under side of the foliage with clean water will keep the latter from getting a foothold. (George F. Stewart.)

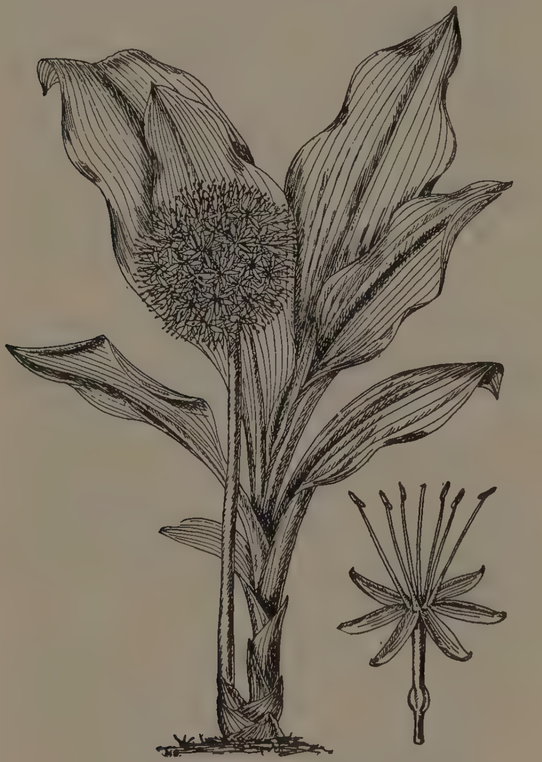
D. *Segms. of perianth. ½in. long or less.*

1. **Lescraûwaetii,** Wildem. Lvs. sheathed at the base, 4–8 in a group, about 7–8 in. long, with 8–9 nerves on each side of the midrib: infl. racemose, the ultimate, umbellate clusters almost round, about 4 in. diam.; fls. rose-colored, showy, the tube short, the segms. linear, about ⅓in. long. Congo region. R.B. 30:217.—Intro. in 1904.



1778. Hæmanthus Katherinæ. (×¼)

DD. *Segms. of perianth. ¾–1 in. long.*

2. **multiflòrus,** Martyn (*H. tenuiflòrus,* Herb. *H. Kálbreyeri,* Baker). Bulb globose, 3 in. or less diam.: lvs. 3–4 on a short, separate st., the petiole short and sheathing, the oblong blade 6–12 in. long, with 6–8 veins each side of the midrib: scape straight, 1–3 ft. high, green or red-spotted; umbel often 6 in. diam., containing 30–100 fls., which are usually blood-red, with linear 3-nerved segms. twice or more as long as the tube; red filaments long-exserted, bearing prominent yellow anthers. Trop. Afr. Variable. B.M. 961, 1995, 3870. L.B.C. 10:912; 20:1948 (erroneously as *H. puniceus*). F.S. 1:58; 23:2377. I.H. 26:354. G. 25:445. Gt. 53:1531. G.W. 4, p. 557. G.Z. 25, p. 170. Var. **supérbus,** Hort., is an improved brilliant-colored form.

3. **Kâtherinæ,** Baker. Fig. 1778. Bulb globose, 2–3 in. diam.: lvs. 3–5, on a short, separate st. appearing with the fls., with a short, spotted petiole, the blade oblong, 9–14 in. long and 4–6 in. broad, the lateral veins 8–10: peduncle 1 ft. tall, spotted toward the base; umbel sometimes 9 in. diam., densely many-fld.; fls. bright red, 2–2½ in. long, the lanceolate reflexing segms. little longer than the cylindrical tube; red filaments exserted. S. Afr. B.M. 6778. G. 32:37. G.C. III. 43:72.—Name spelled both *Katherinæ* and *Katherine*; but the former spelling is the original and the proper Latin form. In cult. the lvs. become "about 3 ft. in length and of a bright pale green color—apple-green, as it is usually called—and the venation is more strongly marked than is usual in *H. multiflorus, H. cinnabarinus* and other allied kinds." Burbidge, Gn. 49, p. 160, with figure.

CC. *Peduncle central as regards the tuft of lvs.*

4. **Líndenii,** N. E. Br. Lvs. 6–8, in 2 ranks, arising from a thick, solid rootstock, nearly or quite evergreen; petioles long, winged; blade 10–12 in. long and 3–5 in. wide, long-ovate, lanceolate or ovate-oblong, acute, the base rounded or subcordate, with a longitudinal fold either side of the midrib: scape 1½ ft. tall, arising from the center of the lvs., flattened on one side, more or less spotted: umbel globular, 6–8 in. diam., with 100 or more scarlet fls. opening in succession; fls. 2 in. across, the tube ¾in. long, the lobes longer and linear-lanceolate and acute. Congo. G.C. III. 8:437; 13:483. I.H. 37:112; 40:173, f. 1; 41, p. 18. Gt. 46, p. 217. G.M. 36:220. J.H. III. 28:73.—Many forms are known in the trade, as var. **mirábilis,** Hort., with salmon-colored fls., a magnificent addition intro. in 1901. G. C. III. 29:332. Var. **imperiàlis,** Hort., differing from the type in longer perianth-segms. G.C. III. 31:99. G.M. 45:85. Var. **Lauréntii,** Hort., also with longer perianth-segms., and salmon-colored fls. R. H. 1911, p. 443. There are many other forms of this popular favorite, such as "Fascinator," "Queen Alexandra," and the like.

BB. *Perianth-parts and spathes ascending.*

5. **puníceus,** Linn. Bulb nearly globular, 2–3 in. diam.: lvs. 2–4, from the bulb, the petiole half the length of the blade, the blade 6–12 in. long and 2–4 in. broad, oblong, strongly undulated, the main veins about 6 on each side the rib: scape 6–15 in. tall, spotted; umbel globose and dense, 3–4 in. diam., bearing many scentless, pale scarlet, yellowish red or rarely white fls. 1 in. long; perianth-tube cylindrical, shorter than the lanceolate 3-nerved segms.; filaments red, 1 in. long. S. Afr. B.M. 1315.

6. **magníficus,** Herb. Bulb globose, 3–4 in. diam.: st. leafy, reaching a length of 2 ft., not developed until after flowering time: lvs. 6–8, oblong, 12–15 in. long, narrowed to a clasping base: peduncles stout, about a foot long, the umbel globose, about 5 in. diam.; fls. bright scarlet, the segms. about twice the length of the tube. Perhaps only a variety of *H. puniceus* and so treated in B.M. 3870. B.M. 4745 figures a var. **insígnis,** Hook., with long green bracts.

AA. *Lvs. thick and fleshy.*

B. *Bracts and fls. white.*

7. **âlbiflos,** Jacq. Bulb or tuber compressed sidewise, with thick, 2-ranged scales: lvs. 2–4, appearing with the fls., nearly erect, obtuse, 6–8 in. long and nearly half as broad, narrowed to the base, green and glabrous, but ciliate on the edges: scape less than 1 ft. tall, pale green, bearing a dense, globular umbel 2 in. diam.; fls. ¾in. long, the linear segms. much exceeding the tube. S. Afr. B.M. 1239. L.B.C. 7:602. Var. **pubéscens,** Baker, has lvs. hairy above. L.B.C. 8:702. B.R. 382. *H. Clárkei,* Hort., is a hybrid of this species and *C. coccineus.*

8. **cândidus,** Bull. Bulb large, globose: lvs. 2, appearing with the fls., fleshy, strap-shaped, about 1 ft. long, 4–5 in. wide, hairy on both sides: peduncle as long as

the lvs., very hairy; heads when expanded 5 in. diam., very showy, white; perianth-tube cylindrical. Natal.

BB. *Bracts and fls. red.*

9. **coccíneus,** Linn. Bulb compressed sidewise, 3 in. diam., the scales many, thick, 2-ranged: lvs. 2, suberect, lingulate, reaching 2 ft. long and 8 in. broad, narrowed to the base, green and glabrous, not ciliate: scape 6–10 in. tall, compressed, mottled; bracts large and thick, ascending and forming a cup, in which the red fls. are borne; fls. 1 in. long, with linear segms. and a short tube. S. Afr. B.M. 1075. L.B.C. 3:240. Var. **coarctàtus,** Baker, has smaller lvs. and shorter bracts. B.R. 181.—Odd plants.

10. **tigrìnus,** Jacq. Lvs. ciliate on the margins, 1 ft. or less long, spotted on the lower part of the back: scape 6 in., red-spotted; umbel dense, 2 in. or less in diam.: bracts shorter than in the last (not over 2 in. long), bright red; fls. 1 in. or less long, with very short tube. S. Afr. B.M. 1705.

Many hybrids and forms are known in horticulture. Among the best is *H. Andrómeda* which is H. Katherinæ × H. magnificus. Fls. crimson. Gn. 76, p. 437. G.M. 55:589.—*H. toxicàrius*=Buphane disticha.

L. H. B.
N. TAYLOR.†

HÆMÀRIA (Greek, referring to the blood-red under surface of the leaves). *Orchidàceæ.* Terrestrial orchids, known to the trade chiefly as Goodyera. They are really dwarf stove foliage plants, and are to be cultivated like Anœctochilus.

In Hæmaria the lower lip is swelled above its base into a wide claw and is provided with a pouch-like sac at base, and a blade of 2 divergent lobes; in Goodyera the blade of the lip is small and not clawed. Both genera belong to a large group in which the lip either has no spur or sac, or if the latter is present, it is included between the sepals; while in Anœctochilus the lip has a prominent sac or spur projecting between the lateral sepals.—Four species, in China and Malaya.

The leaves of *H. discolor* are green above and red below. It is, however, not nearly so brilliant as *Hæmaria Dawsoniana,* which has the same red color beneath, and is beautifully netted above with red or yellow. In both species a dozen or more small flowers, chiefly white, are borne on a densely hairy scape. These plants seem much easier to cultivate than anœctochilus and can be grown in large, shallow pans, with the rhizomes creeping in sphagnum.

A. *Lvs. not netted-veined above.*

díscolor, Lindl. (*Goodyèra díscolor,* Ker). Fig. 1779. Blade of lvs. oblong, 3 in. long, ¾in. wide. China (Brazil, according to Loddiges). B.M. 2055. B.R. 271.—Some plants have white longitudinal markings.

AA. *Lvs. brilliantly netted-veined above.*

Dawsoniàna, Hassl. (*Goodyèra Dáwsonii,* Boxall. *Anœctochìlus Dawsoniànus,* Low). Blade of lvs. elliptic, 3 in. long, 1¼ in. wide. Burma, Philippines. B.M. 7486 (veins of 2 lvs. blood-red; of the other almost wholly yellow) G. 34:101. G.C. III. 35:387.

HEINRICH HASSELBRING.

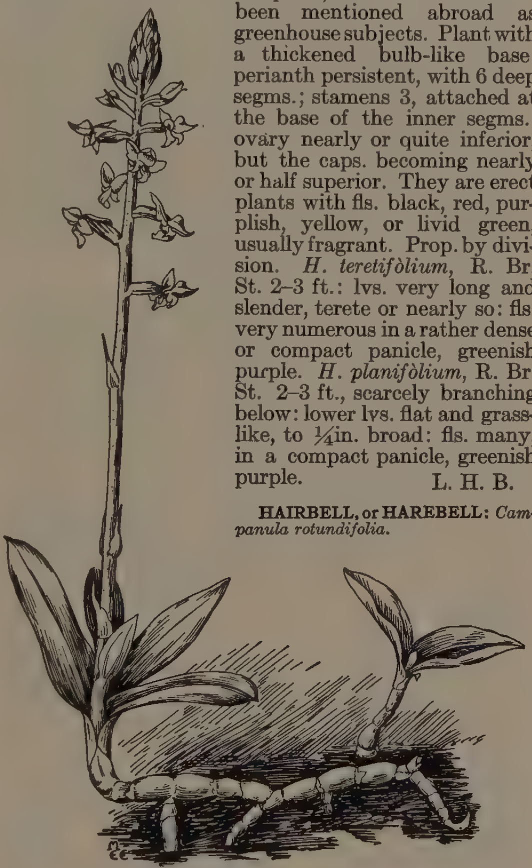
HÆMATÓXYLON (from the Greek for *blood* and *wood,* in reference to the color of the latter). *Leguminòsæ.* Two or 3 species of trees from Mex., Cent. Amer. and W. Indies, of which the most important, *H. campechiànum,* Linn., furnishes the logwood of commerce. It is a medium-sized tree, reaching 30–45 ft., with a short crooked trunk: lvs. abruptly pinnate; lfts. obversely egg-shaped: fls. small, yellow, in axillary racemes; petals 5, oblong, expanding; stamens free, rather upright, with filaments hairy at base; ovary short-stiped, free, with 2–3 seeds: pod lanceolate, flattened, dehiscing along the median valve in 2 boat-shaped pseudo-valves.—The wood is very hard and heavy, the heart-wood, from which the sap-wood has been removed, being used for making the dye. The wood takes on a beautiful brownish red color on exposure to the air. This tree is known as Campeachy wood, logwood, and in Porto Rico as Palo de Campeche.

L. H. B.

HÆMODÒRUM (*blood-gift,* a fanciful name). *Hæmodoràceæ,* which is closely allied to Amaryllidaceæ. Nearly 20 Australian perennial herbs, with sheathing equitant lvs. and different colors of fls. in heads, cymes or spikes, a few of which have been mentioned abroad as greenhouse subjects. Plant with a thickened bulb-like base: perianth persistent, with 6 deep segms.; stamens 3, attached at the base of the inner segms.; ovary nearly or quite inferior, but the caps. becoming nearly or half superior. They are erect plants with fls. black, red, purplish, yellow, or livid green, usually fragrant. Prop. by division. *H. teretifòlium,* R. Br. St. 2–3 ft.: lvs. very long and slender, terete or nearly so: fls. very numerous in a rather dense or compact panicle, greenish purple. *H. planifòlium,* R. Br. St. 2–3 ft., scarcely branching below: lower lvs. flat and grass-like, to ¼in. broad: fls. many, in a compact panicle, greenish purple.

L. H. B.

HAIRBELL, or HAREBELL: *Campanula rotundifolia.*



1779. Hæmaria discolor. (×⅓)

HÀKEA (after Baron von Hake, a German friend of botany). *Proteàceæ.* Australian evergreen shrubs cultivated indoors abroad, much used for ornamental planting in the open in California.

The foliage of the various species of Hakea is exceedingly diverse; in some the lvs. are flat and broad, and then entire or merely toothed, in others they are terete, and then either simple and entire or pinnately parted: fls. in pairs, the pairs commonly crowded in close racemes or globose clusters, these mostly sessile in the lf.-axils; corolla-tube slender, usually recurved beneath the limb, which is mostly globose, the 4 lobes cohering long after the tube has opened; lobes concave and bear sessile anthers; the single style either long or short but always dilated at the end: fr. a hard woody caps. opening in 2 valves and bearing 2 compressed winged seeds.—Ninety-five species are fully described in English, with a key in Flora Australiensis 5:489 (1870). Eleven species grown in Calif. are described and discussed, with a key and 8 illustrations in Univ. Calif. Pub. Botany 4:14–20 (1910).

Hakeas are drought-resistant plants which endure moderate frost and are therefore well adapted to the drier parts of the South and Southwest. In California they are grown as far north as Sacramento. One of these, *H. laurina*, produces strikingly handsome fls.; *H. elliptica* is prized for the bronze color of its young foliage; while the spiny-leaved species are serviceable for planting in public parks or in any place where it is necessary for shrubs to protect themselves from pedestrians or vandals.

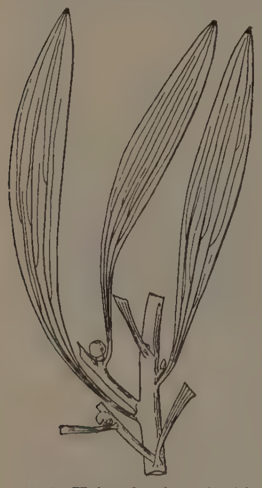
Hakeas may be propagated by cuttings taken from ripened shoots but they are almost universally grown from seeds. These are gathered from year-old capsules which are very hard and must be dried for some time before they will open. The seeds are sown in winter or early spring in the ordinary mixture of sand, leaf-mold, and loam; they germinate easily, even without heat. The young seedlings are pricked off into boxes and held in the lathhouse for a season before planting in the open. For best results hakeas should be grown in light, well-drained soil and need but little water after they are once established; much moisture is injurious except during the summer months.

A. *Lvs. ¼in. or more wide.*

B. *Margins of lvs. flat, entire.*

salígna, Knight. A pale shrub, to 8 ft. high, glabrous except the young shoots: lvs. oblong or lanceolate, 3–6 in. long, obtuse, often callous-tipped, tapering to a short petiole, pinnately veined: fl.-clusters white, small but numerous, dense, sessile; corolla glabrous, recurved: fr. about 1 in. long, ½–¾in. broad, with short incurved beak, roughish.

laurìna, R. Br. (*H. eucalyptoìdes*, Meissn.). Sea Urchin. Fig. 1780. Tall shrub, to 30 ft., and tree-like in Austral.: lvs. elliptic or lanceolate, 5 or 6 in. long, ½–1 in. wide, tapering to a petiole; principal veins 3–7, nearly parallel: fls. crimson, in a globular involucrate head, 1½–2 in. thick, from which the numerous showy golden yellow styles project 1 in. or so in every direction: fr. ovoid, about 1¼ in. long by ¾in. broad, short-beaked. B.M. 7127. G.C. II. 23:149.—The only species with showy fls. here described; equally satisfactory for shrubberies and for hedges; always highly ornamental. In Italy it has been called "the glory of the gardens of the Riviera."



1780. Hakea laurina. (×⅓)

BB. *Margins of lvs. undulate.*

ellíptica, R. Br. Fig. 1781. Erect shrub, 6–15 ft.: lvs. oval or elliptic, nearly sessile, 2–3½ in. long, 1–1¼ in. wide, undulate-margined; veins 5–7, parallel, connected by cross-veinlets: fls. white, in globose sessile clusters: fr. ovoid, 1–1¼ in. long, ¾in. broad, obliquely beaked.—Foliage by far the finest of all intro. kinds, the rich bronze color of the young shoots hardly rivaled among other shrubs. The compact, erect habit makes it eminently suitable for general lawn and shrubbery planting.

AA. *Lvs. or their lobes ⅛in. or less wide, mostly terete.*

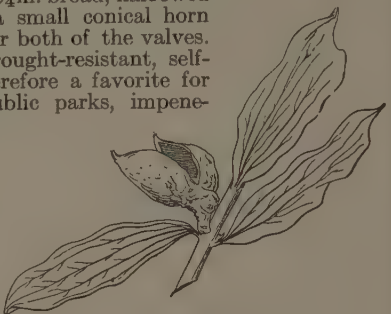
B. *Lf.-veins several: lvs. linear, flat.*

ulícina, R. Br. Shrub with erect branches and dense foliage resembling ulex: lvs. narrowly linear, acute, flat, entire, 1–8 in. long, rarely over ⅛in. wide, prominently 1–3-nerved beneath: fls. very small, glabrous: caps. mostly under ½in. long, the beak short and straight. Var. **carinàta,** F. Muell. (*H. carinàta*, F. Muell.). Lvs. mostly 1-nerved beneath, nerveless above.

BB. *Lf.-veins none.*

suavèolens, R. Br. (*H. pectinàta*, Colla). Rounded shrub, 8–15 ft.: lvs. 2–4 in. long, terete, with rigid spine-like tip, occasionally entire, usually branched into 1–5 rigid terete lobes of unequal lengths: pedicels and perianth glabrous; fls. white, fragrant: fr. ovoid, about 1 in. long by ¾in. broad, narrowed at apex and with a small conical horn near the end of 1 or both of the valves.—Easily grown, drought-resistant, self-protective, and therefore a favorite for depot grounds, public parks, impenetrable hedges, and the like. Makes a suitable covering for dry hillsides, although not deep-rooted and sometimes inclined to become top-heavy.

aciculàris, R. Br. Tall shrub, more slender than the preceding: mature twigs glabrous: lvs. awl-like, simple and entire, 1–3 in. long: pedicels white, silky; the corolla glabrous: fr. ovoid, about 1 in. long, fully ½in. broad, rough, narrowed to a thick beak, each valve with a conic brown horn near apex.—Used for purposes indicated under *H. suaveolens.*



1781. Hakea elliptica. (×⅓)

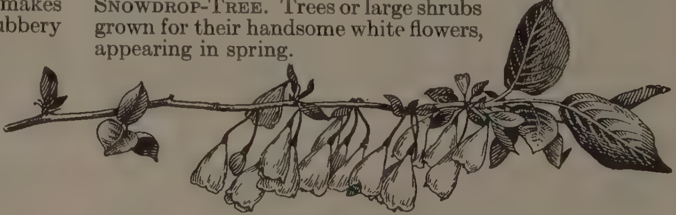
gibbòsa, Cav. Spreading shrub, 6–10 ft., with characters of *H. acicularis* but twigs and young lvs. short-hirsute and fr. larger, about 1½ in. long, nearly 1 in. broad, abruptly narrowed to a short oblique beak, similarly horned. Bot. Cook's First Voy. 266.

pugionifórmis, Cav. Near *H. acicularis* and *H. gibbosa* but to 20 ft. high and corolla as well as pedicels pubescent: fr. much more slender, lanceolate, acuminate, 1 in. long by ¼in. broad, rough around the middle, with an obliquely transverse crest, each valve tapering to a slender point. L.B.C. 4:353. Bot. Cook's First Voy. 265.—Often labeled *H. suaveolens* in nurseries but distinguished from that by the simple lvs. and thicker frs.

H. aquifòlia, is a garden name sometimes applied to H. saligna.—*H. cyclocárpa*, Lindl. Foliage as in H. laurina but lvs. and fr. larger, the fl.-heads not involucrate: corolla silky-pubescent. Once offered by Franceschi.—*H. multilineàta*, Meissn. Related to H. laurina: lf.-veins more numerous: fl.-clusters oblong: fr. only ½in. broad. G.C. III. 19:85 (var.). Reported but apparently never intro.—*H. nítida*, R. Br. Lvs. bright green, oblong, entire or toothed: fls. white, in stalked clusters: fr. 1 in. long by ¾in. broad. B.M. 2246.—*H. undulàta*, R. Br. Lvs. glabrous, obovate or rarely lanceolate: fls. small, in axillary clusters: fr. recurved at base, 1¼ in. long by ¾in. broad, distinctly beaked.—*H. vària*, R. Br. Some lvs. with nearly terete lobes, then resembling H. suaveolens, but varying to flat and holly-like, 1–2 in. long, obscurely veined or veinless, always tapering at the base: fls. in small clusters, the rachis villous, pedicels and small corolla glabrous: fr. ¾in. long by ½in. broad. Offered by Franceschi.

Harvey Monroe Hall.

HALÈSIA (Stephen Hale, 1677–1761, author of a famous work on "Vegetable Statics"). Syn. *Mohrodéndron. Styracàceæ.* Silver-Bell. Snowdrop-Tree. Trees or large shrubs grown for their handsome white flowers, appearing in spring.



1782. Halesia carolina. (×½)

Deciduous and more or less stellate-pubescent: lvs. short-petioled, without stipules, involute in bud, denticulate: fls. in axillary clusters or short racemes on branchlets of the previous year; calyx-tube obconical, slightly 4-ribbed, with 4 minute teeth; corolla campanulate, 4-lobed or nearly 4-parted, white; stamens 8–16; style slender; ovary inferior, 2–4-celled, with 4 ovules in each cell: fr. an oblong, dry drupe with 2–4 longitudinal wings; stone 1–3-seeded.—Three species in N. Amer.

1783. Halesia carolina var. Meehanii. (×½)

The snowdrop-trees are large shrubs or trees with rather large bright green generally oblong and short-stalked leaves and white slender-stalked drooping bell-shaped flowers appearing before or with the leaves and followed by winged light brown fruits. *Halesia carolina* is hardy as far north as Massachusetts and is very handsome in spring when covered with its white flowers. *Halesia diptera* is hardy as far north as Philadelphia and is usually a smaller plant, but has larger flowers and leaves. They thrive in almost any good soil, but prefer a rich well-drained soil and a sheltered position; they are easily transplanted. Propagation is by layers or root-cuttings in spring or autumn; also by greenwood cuttings taken from forced plants. Seed should be sown at once or stratified; if allowed to become dry, it does not germinate until the second or sometimes the third year.

carolìna, Linn. (*H. tetráptera*, Ellis. *Mohrodéndron carolìnum*, Brit.). Fig. 1782. Large shrub or small tree, usually not higher than 40 ft., with spreading branches and often irregular in habit: lvs. ovate or elliptic to ovate-oblong, acute or acuminate, cuneate or rounded at the base, finely serrate, glabrous above, stellate-pubescent below, 2–4 in. long: fls. in clusters of 2–4; corolla 4-lobed, ½–¾in. long; stamens 10–16; ovary 4-celled: fr. 4-winged, 1–1½ in. long. April, May. W. Va. to Fla., west to Ill. and E. Texas. B.M. 910. Mn. 5, p. 194. S.S. 6:257. Gng. 2:247. A.G. 14:211; 18:438. M.D.G. 1899:352, 353. G. 3:526; 10:485. G.C. III. 51: suppl. Feb. 3. Gn. 75, p. 582. Gn.M. 8:22. J.H. III. 44:140. G.W. 5, p. 79. G.M. 55:823. Var. **dialypétala**, Schneid. Corolla divided nearly to the base. Var. **montícola**, Rehd. Pyramidal tree to 90 ft.: lvs. larger, generally oblong-obovate, glabrescent or nearly glabrous below, more sharply serrate: pedicels and calyx glabrous; corolla large: fr. 1½–2 in. long, obcordate at the apex, wings broad. N. C. to Ala., in the mountains. Apparently hardier than the type. Var. **Meèhanii**, Perkins (*H. Meèhanii*, Meehan). Fig. 1783. Bushy upright shrub or small tree: lvs. thicker, smaller, more rugose, darker green, more distinctly serrate, pubescent below: fls. smaller, cup-shaped, shorter pedicelled. A very peculiar form of garden origin; very unlike the species and less ornamental; suggests a hybrid of some kind. G.F. 5:535 (adapted in Fig. 1783).

díptera, Ellis (*Mohrodéndron dípterum*, Brit.). Shrub or small tree, to 30 ft.: lvs. ovate to obovate, rarely oblong, remotely serrate, soft-pubescent beneath, 3–5 in. long: fls. 2–4, in short racemes; corolla deeply lobed nearly to the base, puberulous outside; stamens usually 8; ovary usually 2-celled: fr. oblong with 2 broad wings and often with 2 or sometimes 3 obsolete supplementary ones, 1½–2 in. long. April. S. C. and Tenn. to Fla. and Texas. S.S. 6:259.

H. corymbòsa, Nichols.=Pterostyrax corymbosa.—*H. híspida*, Mast.=Pterostyrax hispida.—*H. parviflòra*, Michx. Shrub, resembling H. carolina: lvs., pedicels, and calyx densely pubescent: corolla ⅓–½in. long: fr. 2-winged. Ga. to Fla.

Alfred Rehder.

HALIMODÉNDRON (Greek, *maritime tree;* referring to its habitat in saline soils). *Leguminòsæ*. Ornamental shrub grown for its handsome profusely produced flowers.

Deciduous: lvs. slender-stalked, with 1 or 2 pairs of lfts. and with the persistent petiole becoming usually spinescent: fls. in lateral slender-stalked, 2–3-fld. racemes; calyx cup-shaped with 5 short teeth; corolla papilionaceous; petals of nearly equal length; standard orbicular with the sides reflexed; keel obtuse, curved; stamens diadelphous; ovary stipitate with many ovules, style filiform, curved: pod stipitate, ellipsoid or obovoid, inflated, tardily dehiscent, with few kidney-shaped glossy brown seeds.—One species in the salt steppes of Cent. Asia from Transcaucasia to the Altai.

This is a wide-spreading shrub with slender branches and small bluish green foliage, covered in early summer with numerous pale violet or rosy purple flowers. The small pale foliage and the slender-stalked drooping flowers combined with the spreading habit give to the plant a gracefulness and airiness of its own and make it a very desirable ornamental shrub. It is perfectly hardy North, resists drought and heat well and thrives in sandy as also in saline and alkaline soils. Propagation is by seeds and by layers which root slowly; it also may be grafted on laburnum or caragana.

halodéndron, Voss (*H. argénteum*, Fisch.). Salt Tree. Fig. 1784. Shrub, to 6 ft.; the young growth silky-pubescent: lfts. 2 or 4, oblanceolate, rounded and mucronate at the apex, grayish or bluish green,

1784. Halimodendron halodendron. (×¼)

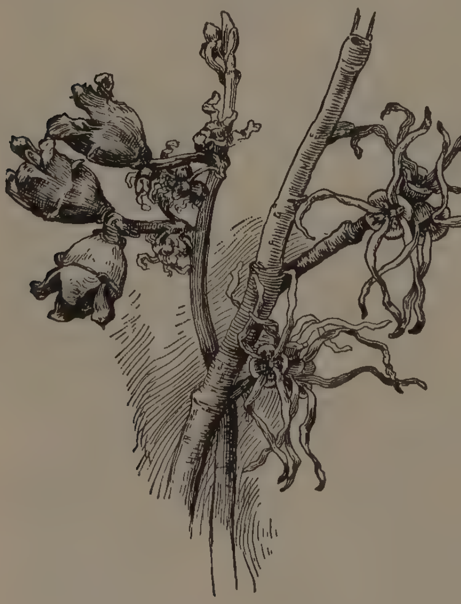
minutely silky, becoming sometimes nearly glabrous with age, ½–1⅓ in. long: fls. 2–3, on slender peduncles about ¾in. long, lilac or pale purple, about ¾in. long: pod ¾–1 in. long; seeds about ⅕in. long. June, July. B.M. 1016. Var. **purpùreum,** Schneid. (*H. argénteum fl. purpùreo,* Hort. *H. speciòsum,* Carr.). Fls. bright rosy purple. R.H. 1876:30. ALFRED REHDER.

HALLÈRIA (Albrecht von Haller, 1708–1777, Swiss physician and naturalist, and professor at Göttingen). *Scrophulariàceæ.* About 6 species of shrubs or small trees from Afr. and Madagascar with opposite, ovate or elliptic, entire or serrate lvs. and axillary, solitary or fascicled fls.: calyx cup-shaped, 3–5-cleft; corolla trumpet- or funnel-shaped with short 4–5-lobed oblique limb; stamens 4, didynamous, inserted about the middle of the tube, about as long as or longer than the corolla; ovary 2-celled; style slender: fr. a berry with several or numerous compressed seeds. Only the following species is sometimes cult. in S. Calif. and as a greenhouse plant abroad for its red fls. and the lustrous nearly evergreen foliage. It is easily prop. by cuttings under glass and by seeds. **H. lùcida,** Linn. Shrub or small tree, to 30 ft., glabrous: lvs. petioled, ovate, acuminate, serrate, 1–4 in. long: fls. in axillary clusters on stalks ¼–½ in. long, tubular, curved and bulged on one side, shortly 2-lipped, red, sometimes yellowish at the base, about 1 in. long; stamens and style exserted: berries subglobose, deep purple, edible. S. and Trop. Afr. B.M. 1744. Sometimes called African honeysuckle.

ALFRED REHDER.

HALOPHŶTUM: *Hoplophytum.*

HAMAMÈLIS (Greek, *hama,* together, and *melon,* apple or fruit: fruits and flowers at the same time). *Hamamelidàceæ.* WITCH-HAZEL. Ornamental woody plants chiefly grown for their yellow flowers appearing late in autumn or in the winter.



1785. Witch-hazel, Hamamelis virginiana, showing flowers and fruits. (Natural size)

Deciduous shrubs or small trees; stellate-pubescent: lvs. alternate, short-petioled, stipulate, sinuate-dentate: fls. in short-peduncled, nodding, axillary, few-fld. clusters, perfect; calyx 4-parted; petals 4, linear, crumpled; stamens 4, very short, alternating with 4 scale-like staminodes; styles 2, short: fr. a dehiscent, woody, 2-celled caps., with 2 shining black seeds. The seeds are shot out with considerable force.—Four species, 2 in E. N. Amer. and 2 in China and Japan. Occasionally writers spell the common name "wych hazel," but there seems to be little historical reason for it. Witch, as used in witch-hazel and witch-elm, is probably allied to "weak," referring to a drooping or straggling habit.

The witch-hazels are hardy ornamental shrubs with medium-sized generally ovate or obovate leaves and yellow flowers with strap-shaped spreading petals in axillary clusters appearing late in fall or in the winter and followed by capsular fruits. *Hamamelis virginiana* is perfectly hardy North, and the other species have proved hardy at least at the Arnold Arboretum.

They are valuable on account of their blooming at a time when hardly any other shrub outdoors is in flower. *H. japonica, H. mollis,* and *H. vernalis* are the only truly winter-blooming shrubs in northern latitudes and are striking objects in the wintry landscape with their bright yellow flowers which are not injured even if the temperature goes down to zero. They are well adapted for shrubberies; of compact, bushy habit and with handsome foliage, turning bright yellow, orange or purple in fall.

They thrive best in somewhat moist, peaty and sandy soil. The Japanese species likes a more sunny position than the American, and is less moisture-loving. Propagation is by seeds, which do not germinate until the second year, or by layers; rarer kinds also by grafting on seedlings of *H. virginiana* in spring in the greenhouse.

A. *Lvs. pubescent below while young, glabrescent or glabrous at maturity.*

B. *Fls. in autumn when the lvs. fall; calyx brownish yellow inside.*

virginiàna, Linn. Fig. 1785. Shrub or small tree, attaining 25 ft.: lvs. oblique and cordate at the base, obovate, coarsely crenate, pubescent on the veins beneath, 4–6 in. long: petals bright yellow, ½–¾in. long; calyx dull brownish yellow inside: fr. surrounded by the calyx to one-half. Sept., Oct. Canada to Fla., west to Neb. and Texas. Em. 472. S.S. 5:198. B.M. 6684. L.B.C. 6:598. A.G. 11:657; 17:771; 44:657 (1890). Gn. 33, p. 589; 39, p. 547.

BB. *Fls. in winter or early in spring; calyx red or purple inside.*

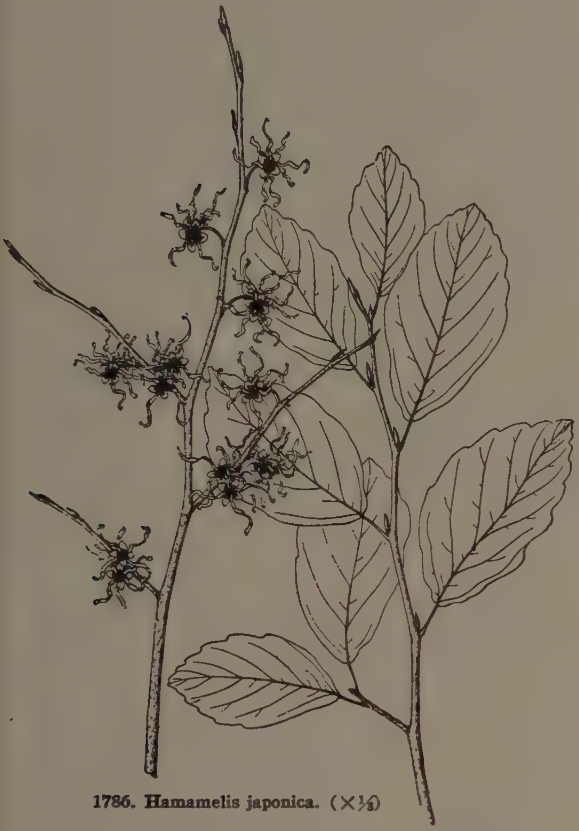
vernàlis, Sarg. Shrub, rarely exceeding 6 ft., suckering: lvs. obovate or oblong-obovate, cuneate and entire below, sinuate-dentate above the middle, pale or glaucescent beneath and glabrous or rusty-pubescent on the veins, only 3–4 in. long: calyx dark red inside; petals light yellow, about ½in. long; ovary one-half superior: fr. surrounded by the calyx about the middle. Jan.–March. Mo. to La. and Okla. S.T.S. 2:156. R.H. 1913, p, 131. B.M. 8573.

japónica, Sieb. & Zucc. Fig. 1786. Shrub or small tree, to 30 ft.: lvs. roundish to oblong-ovate or obovate, sinuately crenate, prominently veined beneath, glabrous or pubescent, 2–4 in. long: petals ¾in. long, yellow; calyx-lobes revolute, purplish or yellow inside; ovary three-fourths superior: fr. surrounded at the base only by the calyx. Jan.–April. Japan. G.F. 4:257 (adapted in Fig. 1786). Gt. 49:1481; 61, p. 136. G.W. 7, p. 405. S.I.F. 2:25. Var. **arbòrea,** Rehd. (*H. arbòrea,* Mast.). Lvs. larger, usually more roundish and of firmer texture: petals golden yellow; calyx deep purple inside: of more vigorous growth. B.M. 6659. R.H. 1891:472. G.C. II. 1:187; 15:205; III. 9:247. G.M. 34:94. Gn. 57, p. 103; 65, p. 59; 69, p. 105. Var. **Zuccariniàna,** Arb. Kew. Differs little from the type; it has pure canary-yellow fls., smaller than those of the preceding variety and opening about 3 weeks later. Gn. 17, p. 251. R.B. 28:62.

AA. *Lvs. densely tomentose below: calyx brownish purple inside.*

móllis, Oliver. Shrub or small tree, to 30 ft.: lvs. orbicular-obovate or obovate-oblong, cuspidate, obliquely cordate at the base, dentate, somewhat rough above, grayish white below, 4–5 in. long: calyx purplish red inside, petals golden yellow, ¾in. long; ovary nearly one-half superior. Jan.–March. Cent. China. B.M. 7884. G.C. III. 52:488. Gn. 75, p. 20. H.I. 18:1742.

Alfred Rehder.



1786. Hamamelis japonica. (×⅓)

HAMÈLIA (Henry Louis Duhamel du Monceau, 1700–1782, prominent French botanical author). *Rubiàceæ.* Ornamental woody plants grown chiefly for their handsome scarlet or yellow flowers and for the attractive black or purple berries.

Evergreen shrubs with terete branches: lvs. membranous, opposite or sometimes in whorls, petioled, entire, with interpetiolar stipules: fls. short-stalked or sessile in terminal forking cymes; sepals 5, upright; corolla tubular or bell-shaped, 5-ribbed, contracted at the base, limb with 5 short lobes; stamens 5, with the filaments connate at the base and inserted above the base of the tube; ovary inferior, 5-celled; style slender with spindle-shaped stigma: fr. a small ovoid or globular berry with numerous minute seeds.—About 13 species, by some reduced to 6, in Trop. and Subtrop. Amer.

These are upright shrubs with herbaceous shoots, rather large, generally ovate-oblong acute leaves and yellow or scarlet flowers in terminal clusters followed by small black or purple berries. They can be cultivated outdoors in subtropical and tropical regions only. Propagation is by seeds and by cuttings of half-ripened wood in early summer under glass.

Of the best-known species much prized in Florida and recommended for northern conservatories under the name of "scarlet bush," E. N. Reasoner writes:

"*Hamelia patens,* a native of the West Indies and Southern Florida, along the coast, a beautiful and almost unknown plant, should become a favorite in greenhouse culture. The leaves have a purplish hue at some seasons of the year, and the flowers are of a bright orange-red color. In Florida it must surely become a favorite for open-air planting, as it is there rarely killed down by frost, and when it is it sprouts up readily from the root, and blooms the following summer. It is in bloom for many months, and without doubt could be forced at any season. With age it becomes a woody shrub, 5 to 12 feet in height. The flowers are succeeded by handsome black berries, which are retained a long while."

A. *Plant glabrous or minutely pubescent.*

pàtens, Jacq. Shrub, to 12 ft.: lvs. opposite or usually in whorls of 3, elliptic-ovate to oblong, acute or acuminate at both ends, minutely pubescent or glabrous, 3–6 in. long; petiole ½–1½ in. long: infl. 2–5 in. across; sepals triangular, short; corolla with narrowly cylindric tube about ¾in. long, scarlet-orange: fr. ovoid, black, ¼in. long. Fla. to Brazil. B.M. 2533.

ventricòsa, Swartz. Shrub or small tree: lvs. usually in whorls of 3, rarely 4, oblong-lanceolate, acuminate, glabrous, 3–5 in. long: fls. yellow, about 1½ in. long, tubular-campanulate, constricted above the base in a terminal few-fld. infl.: fr. ovoid. W. Indies. B.M. 1894. B.R. 1195.—The similar *H. chrysántha,* Swartz (L.B.C. 11:1098) has smaller fls. and smaller more obovate lvs.

AA. *Plant hirsute.*

sphærocárpa, Ruiz & Pav. Shrub, to 12 ft.: lvs. usually in whorls of 3, oblong, acute, undulate, hirsute on both sides, 3–4 in. long: fls. in large terminal cymes, orange-yellow, tubular, about 1 in. long: fr. subglobose, hirsute, purplish black. Peru.

Alfred Rehder.

HAPLOCÁRPHA (probably from Greek for *single chaff,* in reference to the 1-rowed chaffy pappus). *Compósitæ.* Stemless perennials with a woody rhizome: radical lvs. short-petioled, entire or lyrato-pinnatifid, white-tomentose beneath: scapes 1-headed, longer than lvs.: fr. 3–5-ribbed, provided at base with tufts of hairs, naked or hairy above, with a crown of small, pointed pappus-scales.—Four or five species from the Cape region. *H. scapòsa,* Harv., resembles an acaulescent species of Arctotis: lvs. lanceolate to elliptic, 3–9 in. long, green above, white-woolly beneath: peduncles many times longer than lvs., bearing a solitary clear yellow fl.-head, 1½–2½ in. across. G.C. III. 40:124. Sometimes planted in the open, but not hardy N.

L. H. B.

HAPLOPÁPPUS: *Aplopappus.*

HAPLOPHÝLLUM: *Ruta.*

HARDENBÈRGIA (after Franziska, Countess of Hardenberg, sister of Baron Huegel, a well-known traveler.) *Leguminòsæ.* Vines, grown chiefly for their handsome flowers.

Twining herbs or subshrubs: lvs. pinnate with small stipules; lfts. 3 or 5, sometimes reduced to 1, entire, with stipels: fls. papilionaceous, small, on long racemes, ranging from white through pink and rosy purple to violet-blue, often with 1 or 2 green or yellowish spots on the standard; calyx 2-lipped, the upper 2 teeth connate; standard orbicular, with inflexed auricles; keel obtuse, shorter than wings; ovary sessile; style short and thick: pod linear, flat or turgid, with several strophiolate seeds.—Three species in Austral. often referred to Kennedya, which has larger and differently colored fls. solitary or in short racemes, with the keel usually about as long as the wing. The two species in cult. are grown abroad under glass by those who are skilled in managing Australian woody plants; they prefer peaty and porous soil, as they are, like most Australian plants, impatient of too much or stagnant moisture. The species first mentioned is cult. outdoors in Calif. These plants can be trained into bush form. Prop. is by seeds or by greenwood cuttings of lateral shoots under glass in spring.

A. *Lfts. solitary: pods flat, with dry pulp inside.*

monophýlla, Benth. (*Kennédya monophýlla,* Vent. *K. longiracemòsa,* Lindl. *K. cordàta,* Lindl. *K. ovàta,* Sims). Lfts. usually reduced to 1, ovate to narrowly lanceolate, rounded or cordate at the base, obtuse, reticulate, 2–3 in. or sometimes 4 in. long: fls. less than ½in. long, in 2's or rarely 3's, as many as 35 in a raceme, and the upper racemes often forming a terminal panicle. B. 2:84. B.M. 263, 2169. L.B.C. 8:758 and 20:1940. B.R. 944; 1336. R.H. 1896, p. 431. R.B. 22:169.—The fls. range from white through rose and purplish to pure violet, but are never distinctly blue. Var. **álba** and var. **ròsea** are cult.

AA. *Lfts. 3 or 5: pod turgid, without pith or pulp.*

Comptoniàna, Benth. (*Kennédya Comptoniàna,* Link. *K. macrophýlla,* Lindl.). Lfts. 3 or 5, and in the latter case the lateral ones close together in 2 opposite pairs, not opposite in distant pairs, oval to linear-lanceolate, rounded or truncate at the base, obtuse, 1½–3 in. long, rarely longer: fls. similar to those of the preceding species, but usually blue or violet-blue and in pairs or clusters of 3–4 along the racemes. B.R. 298; 1862; 26:60. R.H. 1882, p. 344. J.H. III. 30:361; 44:253. P.M. 8:27, 267. H.U. 5:236. Var. **álba** is cult.

H. retùsa, Benth., is an anomalous species not cult. All other names in this genus are synonyms of the 2 species described above.

ALFRED REHDER.†

HARDHACK: *Spiræa tomentosa.*

HARDY PLANTS. The word "hardy" covers many distinct ideas. It is used to distinguish plants that can be cultivated outdoors the year round from plants that must be grown under glass part or all of the year. For example, in this Cyclopedia plants are spoken of as hardy as far north as Washington, D. C., New York, Boston or Montreal, meaning that the plants are not killed by the winters at these places. In its widest sense, "hardy" indicates resistance to all kinds of unfavorable conditions. Thus, while all the common geraniums are tender plants, one variety may be hardier than another because it withstands intense heat and drought and general neglect. In general, however, the unqualified word "hardy" indicates that the plant is able to withstand the winter of the given place. See the articles *Border* and *Landscape Gardening.* Smaller divisions of the subject of hardy plants are discussed under *Alpine Plants* and *Aquatics.*

HAREBELL: *Campanula rotundifolia.*

HARICOT (French name for *Phaseolus vulgaris*). Same as kidney bean of the English. It is the common garden bean of America, as distinguished from the Windsor or broad bean, lima bean, and others. See *Bean.*

HARÌNA: *Wallichia.*

HARIÒTA: *Hatiora.*

HARLEQUIN FLOWERS: *Sparaxis.*

HARPÀLIUM: *Helianthus.*

HARPEPHÝLLUM (from the Greek for *sickle* and *leaf,* in reference to the falcate lfts.). *Anacardiàceæ.* KAFIR PLUM. Two species, of which **H. cáffrum,** Bernh., is cult. in Fla. and S. Calif. It is a tall, glabrous tree with hard, heavy wood: lvs. thick, lustrous, imparipinnate, alternate, aggregate at top of branches, stalked; lfts. sessile, falcate-lanceolate: fls. small, in compact axillary panicles, diœcious; calyx with obovate segms.; petals 5, narrow-ovate, imbricate the bud; stamens 10 in the male fl., somewhat shor than the petals, inserted below margin of the disk: obovate, with thick woody endocarp, 4-celled, with small, sterile cells, and 2 large fertile cells, dark re size and shape of a large olive, the very thin pulp ha ing a subacid taste; edible. S. Afr.

L. H. B.

HARRÍSIA (named for William Harris, Superinten ent of Public Gardens and Plantations, Jamaica). *C tàceæ.* Upright tall cacti, little planted.

Stems rather slender, sometimes weak: branch fluted and having 8–11 rounded ribs: areoles beari slender needle-like spines: fls. tubular, rather lar growing from near the tips of the branches, nigh blooming: fr. naked, globose, yellow.—About 8 spec known; these confined to the W. Indies.

grácilis, Brit. (*Cèreus repándus* of Cyclo. of Am Hort., not *Cáctus repándus,* Linn.). Sts. said to be 20 long: ribs 8–10: spines in clusters of 9–12: fls. whi the bracts on the tube filled with long white hairs.

J. N. ROSE.

HARTWÉGIA (Theodor Hartweg collected Mex. for the Horticultural Society of London, a found these plants near Vera Cruz). *Orchidàce* Tender epiphytic orchids from Trop. Amer., growi about a foot high and bearing purple fls. The gen has the habit of Epidendrum, section Amphiglott but differs in having the labellum saccate at the ba in which respect the genus approaches Ponera; howev Ponera has a very different habit.—Two speci Rest them in a coolhouse Oct. to March. Growi temperature should be 65–90°.

purpùrea, Lindl. Lvs. solitary, leathery, ovate-lanc late, equally terete with the st., many times shor than the thread-like peduncle: fls. small, purple; sep acute, a little larger than the petals; limb of the white at the base, callous. Mex.

H. gémma, Reichb. f. "This is a most lovely gem," wr Reichenbach, and "much better than its predecessor." Gem therefore, probably does not mean "twin," in this case. I solitary, semi-terete, thick, acute, channelled, blotched w blackish violet: fls. amethyst-purple, in a small, 1-branched pani odd sepal acute, obtusely strap-shaped, equal sepals oblong-ac Cent. Amer.

L. H. B

HASTÍNGSIA (S. Clinton Hastings, San Francis promoter of Californian botany). *Liliàceæ.* Two b bous plants of the Pacific slope, separated by Sere Watson from the genus Schœnolirion (the Oxytria Rafinesque), offered by collectors but little known cultivation.

Plants with white or greenish fls. in many-fld. de panicles or racemes: perianth-segms. distinct, e obscurely 3-nerved; stamens 6; style short; ov oblong-ovate and not deeply lobed (so differing, amo other things, from Schœnolirion, which has a depress globose deeply 3-lobed ovary and fr.). Hastings have strong, nearly naked sts., arising from a tunica bulb: lvs. rather fleshy. Treatment as for camassi

álba, Wats. Mostly stout, 2–3 ft. high: lvs. 1½ or less wide: racemes simple or nearly so, 1 ft. lo densely fld., the fls. ¼in. or less long, white or green white; stamens equaling the segms. Dry hillsides, Calif. northward.

bracteòsa, Wats. Bracts narrow and nearly equal the fls., which are larger than in the other, and wh stamens half as long as segms.: lvs. narrower. S. O in marshes.

L. H. B

HATIÒRA (an anagram of Hariota). *Cactà* Upright cacti, allied to Rhipsalis.

Plants erect, branching: branches short, aris in 2's or 3's from tops of older branches, smooth spineless, bearing several abortive areoles along t sides and each a large woolly terminal one from wh arise the fl. and succeeding branches: fls. terminal; ovary globular, naked or nearly so; sepals usually in 2 rows, the outer ones broader and short, the inner ones larger and more petal-like; petals distinct, narrow toward the base; stamens distinct, erect, borne on the disk; stigmas 5, erect, white. Closely related to Rhipsalis, with which as Hariota it is often united, as it was in the Cyclo. of Amer. Hort.—Some 6 or 7 species of Hariota have been described, but most of these are true species of Rhipsalis; 2 were recognized by K. Schumann. The following is in cult. Hariota, DC. (1834) is a homonym of Hariota, Adans. (1763), and hence the name Hatiora has been substituted.

salicornioìdes, Brit. & Rose (*Hariòta salicornioìdes*, DC. *Rhípsalis salicornioìdes*, Haw.). Plant upright, reaching a height of 18 in., richly branched: areoles hardly setulose or lanate: sts. cereiform, with cylindric or oblong-elliptic joints; mature or fruiting branches with verticillate, club- or flask-shaped joints, with slender base, all apparently, as well as the fls. and fr., growing from the tops of joints: fls. yellow, funnelform, ½in. long: berry small, whitish. Brazil. B.M. 2461.

J. N. Rose.

HAW, or HAWTHORN: *Cratægus*. **BLACK HAW:** *Viburnum prunifolium*.

HAWKWEED: *Hieracium*. Various species of Crepis are known as Hawksbeard.

HAWÓRTHIA (A. H. Haworth, an English botanist of the beginning of the last century, who wrote much and well on succulents). *Liliàceæ*, tribe *Aloìneæ*. Acaulescent or shortly caulescent small succulents.

Leaves usually small, crowded on the st. or in mostly somewhat elongated rosettes: fls. white, green or rosy-striped, tubular with somewhat irregular recurving limb and included style and stamens; segms. of perianth 6, oblong, nearly equal; stamens 6, shorter than perianth; ovary sessile, 3-angled: fr. a loculicidally 3-valved caps., bearing many compressed angled seeds. S. Afr. Monograph by Berger in Engler, Das Pflanzenreich, hft. 33, 1908.—Species 60, occurring in S. Afr. They are interesting condensed or cespitose plants with thick and succulent keeled often tuberculate and sometimes toothed lvs., and fls. in simple or panicled racemes.

Cultivation, propagation and decorative uses as for Aloe, under which, with Apicra and Gasteria, the species were formerly placed. See *Aloe* and *Succulents*.

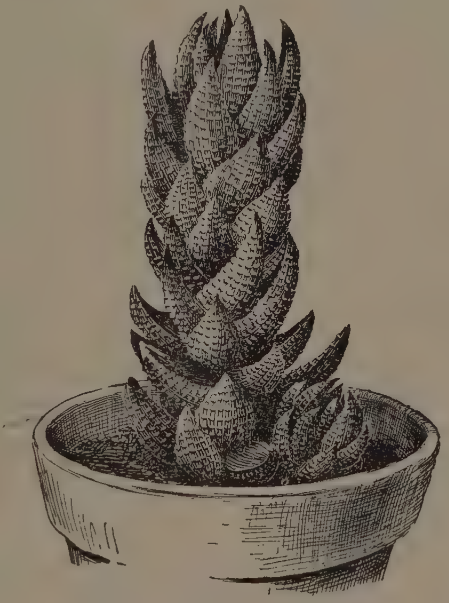
A. *Foliage crowded on an elongated st. (aspect of Apicra).*

B. *Lvs. never coarsely white-dotted.*

C. *The lvs. 3-ranked, concave.*

1. **viscòsa**, Haw. (*Alòe viscòsa*, Linn. *A. triangulàris*, Lam. *Apìcra viscòsa*, Willd.). St. with lvs. 1¼ x 4–8 in., occasionally forked, clustered: lvs. dull green, ½ x 1 in., appressed with spreading tips, minutely scabrous: infl. 1 ft. high, slender and curving, simple; fls. green-lined. Cape. DC., Pl. Gr. 16. B.M. 814. Salm, Aloe §3, f. 3.—The type, with straight ranks of lvs., varies into a form with larger less-crowded lvs., var. **induràta** (*H. induràta*, Haw., *Alòe induràta*, R. & S., *A. viscòsa induràta*, Salm), Salm, Aloe §3, f. *3b;* a small form with more spreading lvs. in somewhat spiral ranks, var. **pseudotortuòsa**, Baker (*H. pseudotortuòsa*, Haw., *Alòe pseudotortuòsa*, Salm, *A. subtortuòsa*, R. & S., *Apìcra tortuòsa*, Willd.), Salm, Aloe §3, f. 5; a dwarf form with straight-ranked, longer, more spreading, nearly smooth lvs., var. **concínna**, Baker (*H. concínna*, Haw., *Alòe concínna*, R. & S., *A. viscòsa màjor*, Salm), Salm, Aloe §3, f. 4. Berger 24; and a taller form with more or less spiral ranks of outcurving lvs. 2 in. long, var. **torquàta**, Baker (*H. torquàta*, Haw., *Alòe torquàta*, Salm), Salm, Aloe §3, f. 6.

2. **tortuòsa**, Haw. (*Alòe tortuòsa*, Haw.). St. 4–5 in., more or less clustered: lvs. dull green, ¾ x 1½ in., ascending in 3 irregularly oblique crowded ranks. somewhat rough on the back: infl. about 1 ft. high, slender, occasionally forked; fls. rosy-lined. Cape. Salm, Aloe §4, f. 2. B.M 1337. Berger 25.—Varies in a form with fleshier lvs., 2 in. long, rough on both faces, var. **pseudorígida**, Berger (*H. subrígida*, Baker, *Alòe pseudorígida*, Salm, *A. subrígida*, R. & S., *Apìcra pseudorígida*, Haw., *Apìcra rígida*, Willd.), Salm, Aloe §4, f. 1. Jacq. Fragm. 108; a still larger, greener, rougher, and more succulent form, var. **màjor**, Berger (*A. pseudorígida màjor*, Salm), Salm, Aloe §4, f. 2β; and a smaller form with the more spirally arranged lvs. smooth above, var. **tortélla**, Baker (*H. tortélla*, Haw.).



1787. Haworthia Reinwardtii. (× ½)

CC. *The lvs. more or less irregularly 5-ranked, spreading.*

3. **hýbrida**, Haw. (*Alòe hýbrida*, Salm). St. with lvs. 2½ x 4–5 in., more or less cespitose: lvs. dull green, ¾ x 1½ in., plump, wrinkled above and roughened: infl. 2 ft. high, branched; fls. brown or rosy lined. Cape (?). Salm, Aloe §4, f. 4.—Possibly a hybrid between the preceding and following species.

4. **rígida**, Haw. (*H. expánsa màjor*, Haw. *Alòe rígida*, DC. *A. cylíndrica rígida*, Lam. *Apìcra expánsa*, Willd.). St. with lvs. 4 x 3–5 in., more or less cespitose: lvs. green or browning or rosy-margined, ½–¾ x 2–2½ in., concave, wrinkled beneath: infl. 2 ft. high, more or less branched; fls. striped with brownish green. Cape. Salm, Aloe §4, f. 3. DC., Pl. Gr. 62. Berger 26. L.B.C. 15:1430.—Varies into a smaller form with slightly glossy, smoother, very spreading lvs., var. **expánsa**, Baker (*H.*

expánsa, Haw., *Alòe expánsa*, Haw. *A. rigida expansa,* Salm. *Apìcra pátula*, Willd.), Salm, Aloe §4, f. 3*b*.

BB. *Lvs. spirally many-ranked, erect, biconvex, white-warty.*

5. **Reinwárdtii,** Haw. (*H. fasciàta,* Haw. *Alòe Reinwárdtii,* Salm). Fig. 1787. St. with lvs. 1½–2 x 4–6 in., somewhat cespitose: lvs. lanceolate, ½ x 1–1½ in., coarsely white-warty in rows on the back: infl. 1–1½ ft. high, somewhat nodding, simple; fls. lined with rose. Cape. Salm, Aloe §6, f. 16. Berger 27. J.H. III. 59, p. 628.—A smaller form is var. **mìnor,** Baker.

6. **coarctàta,** Haw. (*Alòe coarctàta,* R. & S. *H. Reinwárdtii víridis,* Hort.). St. with lvs. 3 x 6–8 in., somewhat cespitose: lvs. triangular, ½ x 2 in., sparingly and finely white-dotted in lines beneath: infl. 1 ft. high, nodding, simple; fls. lined with red. Cape. Salm, Aloe §6, f. 17. Berger 27.

AA. *Foliage in a spirally subradical rosette.*

B. *Lvs. not pellucid, dull and firm.*

C. *The lvs. not hard-margined, with prominent white tubercles.*

7. **margaritífera,** Linn. (*H. màjor,* Duval. *Alòe margaritífera,* Mill. *A. pùmila margaritífera,* Linn. *A. margaritífera màjor,* Haw. *Apìcra margaritífera màjor,* Willd.). Somewhat cespitose: lvs. upcurved-spreading, biconvex, ¾–1 x 3 in., with scattered large pearly tubercles often turning green in age: infl. 2 ft. high, branched; fls. sessile, green-lined. Cape. DC., Pl. Gr. 57. Salm, Aloe §6. f. 5. Berger 28.—The type, with green lvs. coarsely warty on both faces, varies into a form with smaller more spreading lvs., var. **granàta** (*H. granàta,* Haw., *H. mínima,* Haw., *Alòe margaritífera mínima,* Ait., *A. granàta,* R. & S., *A. pùmila margaritífera,* Linn., *A. brèvis,* R. & S.), Dill., Eltham. 16, f. 18. Salm, Aloe §6, f. 6; a large form with smaller closer warts, var. **erécta,** Baker (*H. erécta,* Haw., *H. mìnor,* Duval, *Alòe margaritífera mìnor,* Haw., *A. margaritífera mèdia,* Ait., *A. mìnor,* R. & S., *A. erécta,* Salm), Dill., Eltham. 16, f. 17. B.M. 815. Salm, Aloe §6, f. 7; also into forms with little if any roughening on the upper face, var. **semimargaritífera,** Baker (*H. semimargaritífera,* Haw., *Alòe semimargaritífera,* Salm), otherwise resembling the type; var. **corallìna,** Baker, with smaller tubercles; and var. **subálbicans,** Salm, with whitened lvs., Salm, Aloe §6, f. 1.

8. **fasciàta,** Haw. (*Alòe fasciàta,* Salm. *Apìcra fasciàta,* Willd.). Cespitose: lvs. erect, flattened above, ½ x 1–1½ in., somewhat glossy, with the coarse white tubercles in cross-bands: infl. scarcely 1 ft. high, branched; fls. rosy-lined. Cape. Salm, Aloe §6, f. 15. Berger 28.—A supposed hybrid with *H. attenuata,* which it approaches, is var. **cæspitòsa,** Berger.

9. **rugòsa,** Baker (*H. rádula aspérior,* Haw. *Alòe rugòsa,* Salm., *A. rádula mìnor,* Salm). Somewhat clustered: lvs. ascending, long-pointed, flattened above, ¾–1 x 3–4 in., dull green with smaller white tubercles: infl. 2–3 ft. high, branched; fls. rosy with green veins. Cape(?). Salm, Aloe §6, f. 9.—A deeper green form is var. **pervíridis,** Salm.

10. **subulàta,** Baker (*H. rádula lævior,* Haw. *Alòe subulàta,* Salm. *A. rádula màjor,* Salm). Somewhat clustered: lvs. ascending or outcurved at end, long-attenuate, flattened above, ¾–1 x 4–5 in., green with numerous very small white tubercles beneath: infl. 3 ft. high, somewhat secundly branched; fls. green-nerved. Cape(?). Salm, Aloe §6, f. 10.

11. **attenuàta,** Haw. (*Alòe attenuàta,* Haw. *Apìcra attenuàta,* Willd.). Cespitose: lvs. falcately spreading, pointed, biconvex, ½ x 2–3 in., green with the upper face rough with minute often green points and the back with larger white often banded tubercles or ridges: infl. 2 ft. high, somewhat branched: fls. rosy. Cape. Salm, Aloe §6, f. 12. B.M. 1345 (as *A. radula.*).—Varies into a form with smaller more scattered tubercles, var. **argyrostígma,** Berger (*H. subfasciàta argyrostígma,* Baker), and one with larger and more confluent tubercles, var. **claripérla,** Baker (*H. claripérla,* Haw., *Alòe attenuàta, claripérla,* Salm), Salm, Aloe §6, f. 12 $^{\beta}$.

12. **rádula,** Haw. (*H. rádula multipérla,* Haw. *Alòe rádula,* Jacq. *A. rádula mèdia,* Salm. *Apìcra rádula,* Willd.). Cespitose: lvs. upcurved-spreading, very long-acuminate, flattened above, ¾ x 2½–3 in., green, with irregularly crowded minute tubercles on both faces: infl. 1½ ft. high, branched; fls. green- and rosy-lined. Cape. Jacq., Schoenbr. 422. Salm, Aloe §6, f. 8. Berger 28.

CC. *The lvs. with cartilaginous margin and keel not tuberculate.*

13. **álbicans,** Haw. (*H. lævis,* Haw. *H. ramífera,* Haw. *Alòe álbicans,* Haw. *A. marginàta,* Lam. *Apìcra álbicans,* Willd.). Simple: lvs. ascending or outcurved, pungently acute, concavely triquetrous, 1½ x 3–4 in., glossy, pale, neither roughened nor mottled: infl. 1 ft. high, branched; fls. green- and rosy-lined. Cape. B.M. 1452. Salm, Aloe §5, f. 1. Berger 29.—A greenish form, less margined than in the nearly white type, is var **viréscens,** Baker (*H. viréscens,* Haw. *Alòe viréscens,* R. & S.).

BB. *Lvs. thick, watery-pellucid.*

C. *The lvs. rigid, veiny above, scabrous on the back.*

14. **tesselàta,** Haw. (*Alòe tesselàta,* R. & S.). Little clustered: lvs. bristly toothed, spreading, mucronately short-pointed, ¾ x 1½ in., glossy dull green or reddening above, 5-nerved with an open network of veins, the back scabrous with whitish points: infl. 1–1½ ft. high, simple; fls. nerved with green. Cape. Salm, Aloe §8, f. 1.—Two varieties are distinguished: var. **párva,** Baker (*Alòe párva,* R. & S.) smaller, with the broad lvs. 7-nerved. Salm, Aloe §8, f. 12. Berger 31; and var. **infléxa,** Baker, differing from it chiefly in its more concave lvs. with incurved margin.

15. **recúrva,** Haw. (*Alòe recúrva,* Haw. *A. anómala,* Haw. *Apìcra recúrva,* Willd.). Cespitose: lvs. denticulate, recurved, gradually acute, ¾ x 1½ in., olive-green or purplish, 3- or 5-nerved, the back scabrous with green points: infl. 1 ft. high, simple; fls. red-lined. Cape. B.M. 1353. Salm, Aloe §7, f. 3. Berger 31.

CC. *The lvs. softer, scabrous on the back of the first only.*

D. *Upper face of lvs. abruptly truncately spreading.*

16. **mirábilis,** Haw. (*Apìcra mirábilis,* Willd.). Somewhat clustered: lvs. denticulate, erect, the smooth acute tip almost truncately 3-sided, ¾ x 1½ in., light green or the back purplish, 3- or 5-nerved: infl. 1 ft. high, simple; fls. red-keeled. Cape. B.M. 1354. Salm, Aloe §9, f. 1. Berger 32.

17. **aspérula,** Haw. (*Alòe aspérula,* R. & S.). Little clustered: lvs. denticulate, erect, the 7- to 9-nerved tip scabrid above, ¾ x 1½ in., green: infl. 1 ft. high, nodding; fls. rosy-keeled. Cape. Salm, Aloe §9, f. 2.

18. **retùsa,** Haw. (*Alòe retùsa,* Linn. *Apìcra retùsa,* Willd.). Little clustered: lvs. subentire, spreading in age, the 5- to 8-nerved mucronate tip smooth, ¾ x 1½–2 in., light green: infl. 1 ft. high, simple; fls. nearly sessile, green-keeled. Cape. DC., Pl. Gr. 45. B.M. 455. Salm, Aloe §9, f. 3.—With scarcely mucronate less regularly nerved lvs. it is var. **mútica,** Haw.

19. **túrgida,** Haw. (*Alóe túrgida,* R. & S.). Cespitose: lvs. subentire, ascending, the acute smooth biconvex or 3-sided lvs. truncately spreading, tip 3- to 7-nerved and somewhat dotted, ¼ x ½–¾ in., glossy light green. infl. 8–10 in. high, simple; fls. green-nerved. Cape. Salm, Aloe §9, f. 5. Berger 32.

DD. *Upper face of lvs. obliquely or obscurely if at all subtruncate, not aristate.*

20. **cymbifórmis,** Haw. (*H. concàva,* Haw. *Alòe cymbifórmis,* Haw. *A. cymbæfòlia,* Schrad. *Apìcra cymbæfòlia,* Willd.). Cespitose: lvs. entire, smooth, ascending, oblong, the point often abruptly deciduous, leaving a scar, about 7-nerved with cross-veins, ¾ x 1½ in., pale and glaucescent: infl. 1 ft. high, simple; fls. red-keeled. Cape. Icon. Sel. Horti Thenensis, 105. B.M. 802. Neues Journ. Bot. 2:2. Jacq., Fragm. 112, f. 1. Salm, Aloe §11, f. 1. Berger 33.—A smaller form with blunter more conspicuously lined lvs. 1 in. long is var. **obtùsa,** Baker (*H. obtùsa,* Haw. *Alòe hèbes,* R. & S.).

21. **reticulàta,** Haw. (*Alòe reticulàta,* Haw. *A. arachnoìdes reticulàta,* Ker. *A. herbàcea,* DC. *Apìcra reticulàta,* Willd.). Cespitose: lvs. smooth, finely denticulate, acute, with about 10 connected nerves, ⅜ x 1 in., light green: infl. 1 ft. high; fls. rosy-lined. Cape. Salm, Aloe §10, f. 1. B.M. 1314.

DDD. *Upper face not truncately spreading at end, aristate.*

E. *Shape of lvs. broad, acute, not scabrous, denticulate or ciliate.*

22. **altilínea,** Haw. (*H. mucronàta,* Haw. *H. límpida,* Haw. *H. aristàta,* Haw. *H. polyphýlla,* Baker. *Alòe altilínea,* R. & S.). Cespitose: lvs. upcurved, biconvex, reticulated, ¾ x 2 in., light green: infl. 1 ft. high, simple; fls. green-lined. Cape. Salm. Aloe §11, f. 3.

23. **cuspidàta,** Haw. (*Alòe cuspidàta,* R. & S.). Nearly simple: lvs. ascending, abruptly pale-tipped, turgid, with 3 connected nerves, ½ x 1 in., pale green: infl. 1 ft. high, simple. Cape.

EE. *Shape of lvs. narrow, long-pointed.*

24. **arachnoìdes,** Haw. (*Alòe arachnoìdes,* Ait. *A. pùmila arachnoìdes,* Linn. *Apìcra arachnoìdes,* Willd.). Simple: lvs. upcurved, rather 3-sided, toothed on the keels, with 8 or 9 somewhat connected nerves, ½ x 2–3 in., glaucescent: infl. 1–1½ ft. high, simple; fls. sessile, rosy-lined. Cape. DC., Pl. Gr. 50. B.M. 756. Salm, Aloe §12, f. 2. Jacq., Schoenbr. 421(?).

H. atróvirens, Haw. Leafy st. very short, the rosettes stoloniferous: lvs. 30–40, dense, oblong-lanceolate, ½–¾ in. long, dull green, reddish brown when old, with 3–5 vertical green lines: scape simple, 6 in. S. Afr. B.M. 1361.—*H. Pèarsonii,* C. H. Wright. Stemless: lvs. crowded, ½ x 1¼ in., pale green, with 2 rows of cilia on back, each with bristle on apex: scape 10 in. long. S. Afr.

William Trelease.

HAWTHORN: *Cratægus.* **Hawthorn, East Indian:** *Raphiolepis.*

HAYLÓCKIA (Matthew Haylock, gardener to Dean Wm. Herbert, the latter authority on amaryllids). *Amaryllidàceæ.* A small bulb, not unlike a crocus in habit, blooming in spring; allied to Zephyranthes.

South American: lvs. linear, all radical: scape very short bearing a solitary fl., with a slender tube 1–1½ in. long and a limb of about equal length; stamens affixed in the throat and shorter than the lobes; ovary 3-celled, with the filiform style included in the perianth-tube and the stigmas short-linear. *H. pusílla,* Herb., the only species, is likely to appear in the American trade. The fl. has a greenish tube, the limb whitish or straw-colored and stained outside with purple, apparently somewhat variable in color (sometimes pale rose): bulb globose, with brown appressed scales: lvs. appearing after the fls., the latter coming in England in July to Sept. and ephemeral. Extra-trop. S. Amer., in the region of Montevideo and Buenos Ayres. B.R. 1371. B.M. 7693. From Zephyranthes it differs in the very short or almost wanting scape, the ovary being practically in the bulb-neck. L. H. B.

HAZÁRDIA (Barclay Hazard, Californian botanist). *Compósitæ.* Small shrubs, with silvery leaves and peculiar, not pretty, heads of flowers, borne in August. One is suitable for rockeries and bedding out, but there are better woolly-leaved plants in cultivation.

The genus has about 4 speces of stout, tomentose, deciduous subshrubs of Calif., and at least 1 species from the islands off the coast: heads white-tomentose, numerous, in large cymose panicles, which terminate the branches; rays 5–8, neutral, very short, ligulate or irregularly 5-toothed or lobed, pale yellow changing to brownish purple. In 1887, E. L. Greene made this new genus, remarking that it differs from Diplostephium mainly in habit, the paucity, reduced size, and different color of its rays. It also lacks the tuft of hairs characteristic of the style-tips of Corethrogyne.

detónsa, E. L. Greene (*Corethrógyne detónsa,* Greene). Branches very leafy up to the base of the loose panicle: lvs. of firm texture, 2–4 in. long, obovate-oblong, coarsely serrate; upper surface of older lvs. partly divested of the white tomentum which covers all other parts of the plant. G.C. III. 28:470.

N. Taylor.†

HAZEL-NUT. The nuts of Corylus (which see). In North America, the term is mostly applied to the native species of Corylus, and the word filbert is used more or less indiscriminately for the nuts of the Old World species. (See *Filbert.*) In the present article, the term hazel-nut is used generically for the fruits of all the species. Fig. 1788.

The three native hazels, *Corylus americana, C. californica* and *C. rostrata,* have been sparingly introduced to cultivation, but have not developed varieties worthy of naming or propagating. The foreign species, *C. Avellana, C. pontica* and *C. maxima,* and perhaps others, were introduced along the Atlantic seaboard at an early day and are maintained in gardens throughout the New England and Middle Atlantic States. Efforts to make extensive culture profitable in the eastern United States have hitherto failed, probably from attacks of a fungous disease, *Cryptosporella anomala,* common on *C. americana,* but not specially injurious to that species. It attacks and destroys the young branches, and later the older branches and trunk, without killing the root. Bordeaux mixture has been suggested as a preventive, but recorded successful experiments are lacking. Experimental plantings on the Pacific slope indicate greater success with imported hazels there than in the East, but they have not developed commercial importance.

The requirements of the filbert in America, so far as known, are: moderately rich, well drained soil; absence of *Corylus americana* from vicinity; freedom from mild periods in winter and late frosts in spring. It is specially subject to frost-injury, as both staminate and pistillate catkins develop in fall and quickly swell and open under the influence of mild weather in winter. The staminate catkins commonly bloom first. If they are destroyed by frost, fertilization can be accomplished by suspending branches from other localities, even of other species.

Propagation by seeds is easily done by stratifying in fall and planting in nursery rows in early spring. Seedlings vary exceedingly, and varieties are perpetuated by budding, grafting, suckers or layers, commonly by the last two methods. A considerable supply of well-rooted suckers can be secured from fruiting trees by banking in summer with rich soil or stable manure to promote root-formation. Stools for layering should be heavily manured to force long and slender shoots suitable for bending. These should be staked down in winter or spring and covered with earth. They may be removed to nursery rows or orchard at end of first season.

Planting should be at a distance of 10 to 20 feet in well-prepared soil, in fall or spring. Ground may be cropped with low-growing, cultivated plants while trees are young, but should be maintained in good tilth and fertility.

Pruning is of special importance with this nut. Trees are usually headed at height of 1 or 2 feet, though often permitted to take natural form, which is that of a many-stemmed bush, designated a "stool." Trees are classified according to height of clear trunk into "standard," "half-standard," and "dwarf standard." A short trunk, with vaseform head of six or more branches, is preferred. Suckers should be kept down, unless desired for propagation. Both sexes of blossoms are borne on one-year-old lateral twigs or spurs. March or April, after flowers of both sexes have bloomed, is considered best time for pruning, as unnecessary sacrifice of pollen can thus be avoided. Strong shoots should be headed back to promote spur-formation, and old wood that has borne fruit should be removed annually.

The nuts should not be gathered until ripe, a condition indicated by the browning of the edges of the husk. If left until fully ripe, many of the fruits will rattle out and be lost. The highest prices are obtained for freshly gathered nuts in the husks. To prevent husks from molding, they should be well dried or slightly sulfured. Hazelnuts may be held for considerable periods in tight receptacles, as casks or jars by sprinkling salt over them and storing them in a cool, dry place, or in a refrigerated compartment.

Few insects trouble the European hazel-nuts in America, the nut-weevil of Europe, *Balaninus nucum*, not having yet been naturalized. *B. nasicus* sometimes does considerable injury to the native species.

Nuts and filberts are terms loosely used abroad, especially in England, to designate certain rather indefinite forms of *Corylus Avellana* and *C. maxima*. In general, such varieties as have husks shorter than their fruits are termed nuts, while such as have husks as long as or longer than their fruits are designated filberts.

But few varieties are known in America, most of the hazels grown being seedlings from imported nuts. Varieties of *Corylus Avellana* and *C. maxima* are not clearly distinguishable, but in general those with husks longer than the nuts are assigned to *C. maxima*, and those with short husks to *C. Avellana*.

Alba (White Filbert).—Regarded in England as one of the best varieties. Can be kept in husk longer than most others because of constricted form of husk. Kernel covered with a white skin. Known as Avelinier Blanche, Wrotham Park, etc. Succeeds in California.

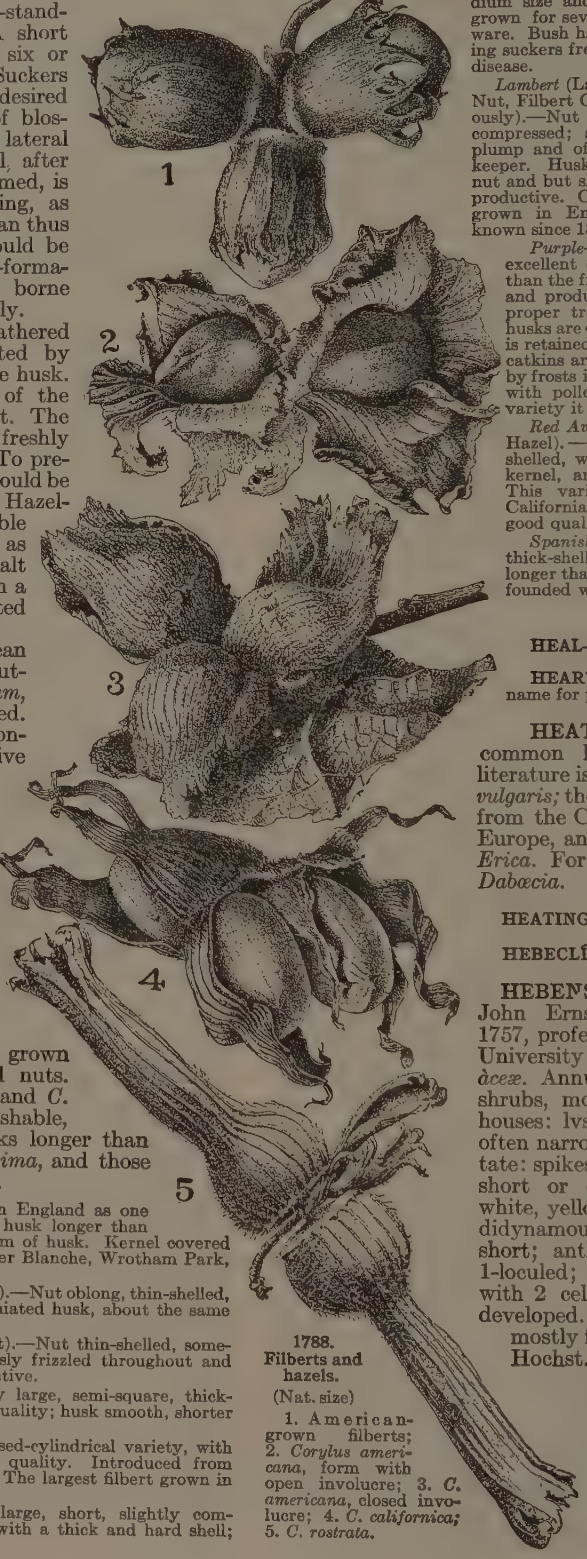
Cosford (Miss Young's, Thin-shelled).—Nut oblong, thin-shelled, of excellent quality; in a hirsute, laciniated husk, about the same length as nut.

Crispa (Cape Nut, Frizzled Filbert).—Nut thin-shelled, somewhat flattened, late; in husks curiously frizzled throughout and wide open at the mouth. Very productive.

Downton Large Square.—Nut very large, semi-square, thick-shelled and well filled, of the highest quality; husk smooth, shorter than nut.

Du Chilly.—A fine, large, compressed-cylindrical variety, with moderately thick shell, and of fine quality. Introduced from France by Felix Gillet, of California. The largest filbert grown in America so far as known.

Grandis (Round Cobnut).—Nut large, short, slightly compressed, of good quality when fresh, with a thick and hard shell; in a short husk, much frizzled and hairy. One of the best varieties; considered the true Barcelona nut of commerce. Also known as Downton, Dwarf Prolific, Great Cob, Pearson's Prolific and Round Cob.



1788. Filberts and hazels. (Nat. size)
1. American-grown filberts; 2. *Corylus americana*, form with open involucre; 3. *C. americana*, closed involucre; 4. *C. californica*; 5. *C. rostrata*.

Jones.—A short, roundish nut, of medium size and good quality, somewhat grown for several years in central Delaware. Bush hardy and vigorous, producing suckers freely, and thus far free from disease.

Lambert (Lambert's Filbert, Lambert's Nut, Filbert Cob; Kentish Cob, erroneously).—Nut large, oblong, somewhat compressed; shell rather thick; kernel plump and of rich flavor; an excellent keeper. Husk quite smooth, longer than nut and but slightly cut in margin. Tree productive. Considered the best variety grown in England, where it has been known since 1812.

Purple-leaved.—Nut large and of excellent quality; in a husk longer than the fruit. Planted for ornament, and productive of good nuts under proper treatment. The leaves and husks are of a deep purple color, which is retained until frost. The staminate catkins are tender and often injured by frosts in winter, but when supplied with pollen from some more hardy variety it yields large crops.

Red Aveline (Avelineer Rouge, Red Hazel).—Nut large, ovate, thin-shelled, with a smooth, red-skinned kernel, and of sweet nutty flavor. This variety is prized in eastern California as a productive sort of good quality.

Spanish.—Nut very large, oblong, thick-shelled, with a smooth husk longer than the fruit. Sometimes confounded with Grandis.

W. A. TAYLOR.

HEAL-ALL: *Brunella.*

HEART'S EASE: Old English name for pansy, *Viola tricolor.*

HEATH, HEATHER. The common heather of Old World literature is a hardy plant, *Calluna vulgaris;* the greenhouse heaths are from the Cape of Good Hope and Europe, and belong to the genus *Erica.* For St. Dabeoc's heath, see *Dabœcia.*

HEATING: *Greenhouse heating.*

HEBECLÍNIUM: *Eupatorium.*

HEBENSTREÌTIA (named for John Ernst Hebenstreit, 1703–1757, professor of medicine in the University of Leipzig). *Selaginàceæ.* Annual herbs, subshrubs or shrubs, mostly grown in greenhouses: lvs. alternate or opposite often narrow, entire or often dentate: spikes terminal, often dense, short or elongated; fls. sessile, white, yellow or pink; stamens 4 didynamous, included, filaments short; anthers oblong or linear, 1-loculed; ovary 2-loculed: fr. with 2 cells, often one not well developed.—About 30 species, mostly from S. Afr. **H. comòsa,** Hochst., is grown as a half-hardy annual (plant perennial). One to 4 ft. high: lvs. numerous, lanceolate or elliptic-lanceolate, glabrous, ½–2 in. long; spikes elongate, 2–6 in. long, mignonette-like; cor-

olla yellow or white, with an orange-red blotch on the limb; tube slender; lobes oblong, inner pair much narrower and scarcely longer than the outer. B.M. 7895. May be safely sown outdoors in April. Fls. fragrant.
L. H. B.

HÉCHTIA (J. G. H. Hecht, who died in 1837). *Bromeliàceæ.* Mexican succulent plants, one species of which is perhaps cult. in a very few fanciers' collections of tender plants for its dense rosettes or recurved spiny lvs., which are purple above from the middle to the tip and silvery beneath. The genus is distinguished by having diœcious fls. The fls. have no decorative value, being ⅛in. across, white, in small sessile, axillary, yellow-bracted heads, borne at intervals of an inch or so on a very slender scape 2 ft. long.—Fifteen species. Give perforated pots and high temperature.

glomeràta, Zucc. (*H. Ghièsbreghtii,* Lem.). Lvs. 10–18 in. long, rigid, leathery, 9–12 lines wide at base, narrowed gradually to the sharp-pointed apex: bracts sheathing, acuminate: corolla 3-lobed nearly to the base; stamens 6; ovary 3-celled. B.M. 5842. I.H. 10:378.—Soil of chopped moss, old manure and charcoal.

argéntea, Baker. Lvs. about 1 ft. long, stiff and spiny, more or less shining silvery: infl. many-fld.; fls. subsessile; petals elliptic, white, concave; style wanting. Habitat doubtful, perhaps Mex.—Well worth growing as a foliage plant in choice collections.
L. H. B.

HECKÈRIA (named for a German botanist). *Piperàceæ.* About 8 S. American and 1 Old World woody plants, distinguished in Piper (with which it is often united) by the many more or less umbellate elongated dense spikes, perfect sessile fls., 2–3 stamens, small anthers with confluent 2-valved cells, obtuse ovary, 3 stigmas: lvs. large, sometimes peltate. *H. umbellàta,* Kunth (*Piper umbellàtum,* Linn. *Pothomórphe umbellàta,* Miq.), is probably not now in the trade. It is a shrub with roundish-reniform not peltate 11–13-nerved petioled lvs., and 4–7 spikes in an umbel; it occurs from Cuba to Brazil. G.W. 9, p. 445.
L. H. B.

HEDEÒMA (Greek, *sweet smell*). *Labiàtæ.* AMERICAN PENNYROYAL. Small aromatic annuals, not of horticultural importance.

Leaves opposite, small: fls. very small, blue or purple, in loose clusters in the axils, the clusters becoming terminal; calyx tubular or ovoid, 13-nerved, the mouth contracted in fr.; corolla 2-lipped, the upper lip erect and entire or lobed; perfect stamens 2, ascending under the upper lip; staminodia 2 or 0.—The genus has about 16 species, all American. The pennyroyal of the Old World is *Mentha Pulegium,* sometimes cult. for its lvs. and tops, which are used as culinary herbs.

pulegioìdes, Pers. AMERICAN PENNYROYAL. Annual, 6–18 in, high: st. very slender, much branched, pubescent: lvs. opposite, ovate to oblong-obovate, sparingly serrate in the upper portion, mostly obtuse at the apex and narrowed at the base, ½–1½ in. long: fls. in axillary clusters; corolla purple, 2-lipped, the lower one with 3 large lobes. July–Sept. B.B. 3:106.—This is of no ornamental value, but the seeds are offered by dealers to those who desire to cult. the plant for its medicinal oil, which is sold in drugstores. It is said to be offensive to mosquitos. The plant can be easily naturalized in dry, sandy spots. It is common in woods and along roads.
L. H. B.

HÉDERA (ancient Latin name of the ivy). *Araliàceæ.* IVY. Ornamental woody root-climbing vines grown for their handsome persistent foliage.

Evergreen shrubs, climbing by aërial rootlets: lvs. alternate, long-petioled, entire or coarsely dentate or 3–7-lobed: fls. perfect, pedicelled, in umbels arranged in terminal racemes or panicles; calyx 5-toothed; petals and stamens 5; ovary 5-celled; style short, cylindric: fr. a 3–5-seeded berry.—Five species (or 6, if *H. helix chrysocarpa* is considered a distinct species) in Eu., N. Afr. and from W. Asia through Cent. Asia to Japan. Monograph by Fr. Tobler, Die Gattung Hedera (1912); a good popular monograph is Shirley Hibberd's "The Ivy: A monograph, comprising the history, uses, characteristics, and affinities of the plant, and a descriptive list of all the garden ivies in cultivation." London, 1872. Many araliads have been described formerly as species of Hedera which are now referred to other genera.

The ivies are climbing shrubs, with inconspicuous greenish flowers appearing in fall, and black, rarely yellow, red or whitish berries ripening the following spring. *Hedera helix* is hardy in sheltered places as far north as Massachusetts; at the Arnold Arboretum a form introduced from the Baltic provinces, Russia, under the name *H. helix baltica* has proved hardier than any other form. All other species, also most of the variegated forms of *H. helix* and its var. *hibernica,* are tender, but the Japanese species has not yet been sufficiently tested.

The ivy is a very valuable plant for covering walls, rocks, trunks of trees and trellis-work, and sometimes climbs very high. It may also be used for covering walls in cool greenhouses, for screens in drawing-rooms and for hanging-baskets. It is a popular window-garden plant, enduring many uncongenial conditions and thriving without bright sunlight. In shady places under trees it makes a handsome evergreen carpet, and is also often used for borders of shrubberies or flower-beds.

It grows in almost any soil, but best in a somewhat moist and rich one, and in shaded positions. The climbing or creeping branches do not flower; flowers are produced on erect, bushy branches, appearing on old, high-climbing plants only. Propagation is by cuttings of half-ripened wood at any time of the year in the greenhouse or in frames, or, in more temperate regions, in the open ground in fall; gentle bottom heat will hasten the development of roots considerably; also increased by layers and by seeds which must be sown soon after ripening and germinate slowly, usually not until the second year. The slow-growing forms, especially the shrubby ones, are often grafted on cuttings of strong-growing varieties, as they do not grow readily from cuttings.

A. *Pubescence of the infl. and the young growth grayish, stellate.*

hèlix, Linn. IVY. ENGLISH IVY. Fig. 1789. High climbing or creeping: lvs. usually 3–5-lobed, dark green above, pale or yellowish green beneath,—those of the flowering branches entire, generally ovate: calyx with minute teeth; calyx, pedicels and tips of young branches covered with grayish white stellate hairs with 5 or 6 rays: fr. black, sometimes yellow. Eu., Canaries, N. Afr., Asia.—A very variable species, of which more than 60 varieties are cult. in European gardens. The first 3 varieties enumerated below are geographical varieties found growing wild, while the others are merely horticultural forms of garden origin. Var. **hibérnica,** Kirchn. (var. *scòtica,* Hort., var. *irlándica,* Hort.). Lvs. larger and broader, of lighter color and thinner texture, with short and broad lobes, often subcordate at the base: umbels and frs. larger; stellate hairs more often with 8 or occasionally 12 rays. Ireland. Var. **chrysocárpa,** Tenore (*H. poetàrum,* Bertol. *H. chrysocárpa,* Walsh). Lvs. less deeply lobed, bright or yellowish green, often undulate, those of the flowering branches narrower: fr. yellow. Turkey, Greece, Asia Minor. Var. **taùrica,** Rehd. (*H. poetàrum* var. *taùrica,* Tobler. *H. taùrica,* Hort.). Lvs. narrower, usually undulate, bright green, those of the sterile shoots usually sagittate, with elongated middle lobe and 1 or 2 short spreading lobes on each side at the base: rather more pubescent, stellate hairs with about 8 rays. Crimea. Possibly hybrid of *H. helix* and *H. colchica.*—The following are some of the most remarkable of the horticultural forms: Var. **arboréscens,** Loud. (*H. arbòrea,* Hort.). Not climbing, forming an erect, low shrub: lvs. ovate to elliptic, entire. This variety is gained by using flowering branches for prop. There are also some variegated forms, as Silver Queen, with silvery variegated lvs. Var. **bàltica,** Hort. A small-leaved form hardly differing from the type; the hardiest or one of the hardiest of the forms in cult. Var. **Cávendishii,** Koch (var. *marginàta mìnor,* Hort.). Slow-growing, with rather small dull green lvs., edged creamy white, striped red or pink in fall. Var. **conglomeràta,** Nichols. Slow-growing: lvs. crowded, small, entire or 3-lobed, undulate. R.H. 1890, p. 163. Var. **crenàta,** Hibberd (*H. vitifòlia* and *H. digitàta nòva,* Hort.). Similar to var. *digitata,* but lobes shorter and broader, crenate at the margin, light green. Var. **deltoídea,** Hibberd (var. *hastàta,* Hort.). Lvs. rather small, bluntly deltoid, almost entire, blackish green, changing to dull purplish bronze in fall. Gn. 25, p. 141; 34, p. 493 (as *A. hastata*). Var. **digitàta,** Loud. Lvs. rather large and broad, digitately lobed with 5 triangular-oblong lobes, sometimes with 2 small additional basal lobes, truncate at the base, dark green. Gn. 25, p. 141; 34, p. 493. Var. **grácilis,** Hibberd. Lvs. rather small, with broad, short lobes, dull green, bronzy in fall. Gn. 59, p. 154. Var. **lobàta màjor,** Hibberd. Similar to var. *hibernica,* but lvs. somewhat smaller, more deeply lobed and lobes narrower. Var. **lùcida,** Hibberd. A form of var. *chrysocarpa,* with large deltoid lvs. not lobed or partly or slightly 3–5-lobed, glossy above: a vigorous grower. Gn. 25, p. 141; 34, p. 492. Var. **lusitánica,** Hesse. Similar to var. *palmata.* Lvs. large, to 5 in. across, light green, palmately 5-lobed with triangular lobes. Var. **maculàta,** Hort. (*H. latifòlia maculàta,* Hort.). Similar to var. *hibernica:* lvs. spotted and striped yellowish white. Var. **marginàta,** Hort. Lvs. broadly triangular-ovate, irregularly bordered yellowish white, striped red or pink in fall: of somewhat slow growth. F.E. 31:318. Var. **marmoràta,** Hort. Similar to var. *hibernica,* but lvs. irregularly blotched yellowish white. Var. **mínima,** Hibberd (var. *donerailénsis,* Hort.). Lvs. small, 3-lobed or pedately 5-lobed, with short and spreading basal lobes, dull purplish brown in winter. Gn. 59, p. 154. M.D.G. 1897:229 and S.H. 2:237 (as var. *digitata*). Var. **palmàta,** Hort. Similar to var. *digitata,* but lvs. 3–5-lobed with broader distinctly triangular lobes, the lateral ones more spreading, dull green. Var. **pedàta,** Hibberd. Lvs. pedately 5-lobed, the middle lobe long and narrow, the lateral lobes much shorter, dark green with whitish veins. Gn. 25, p. 141; 34, p. 493; 59, p. 154. Var. **sagittifòlia,** Koch. Lvs. rather small, with triangular middle lobe and short, broad and obtusish lateral lobes, deeply cordate at the base, dull dark green. Var. **tesselàta,** Nichols. Lvs. 3-lobed with short and broad lobes, with a distinct reticulate variegation. J.H. III. 28:209; 45:99. Var. **tortuòsa,** Hibberd. Lvs. ovate or rhombic, entire or obscurely 3-lobed, more or less curled and twisted, the curling increasing during cold weather. Gn. 55, p. 336. Var. **trícolor,** Hibberd (var. *marginàta rùbra,* Hort., var. *elegantíssima,* Hort., var. *Cúllisii,* Hort.). Like var. *marginata,* but edges of lvs. becoming red in fall.

1789. Hedera helix. Form with white-ribbed leaves. (×⅓)

canariénsis, Willd. (*H. hèlix* var. *canariénsis,* DC. *H. algeriénsis,* Hort. *H. maderénsis,* Hort. *H. azòrica,* Hort.). High-climbing: pubescence more scaly, hairs with 12–20 rays: lvs. large, bright green, roundish ovate, usually cordate at the base, entire or with 3–7 rather short lobes of almost equal size: umbels larger, often solitary or few; calyx-lobes broader: frs. black, sometimes ½in. thick. Canary Isls., Madeira, N. Afr. Gn. 25, p. 141; 34, pp. 492, 496. G.M. 54:319. Var. **arboréscens,** Koch. Not climbing, forming an upright low shrub. G.M. 54:957. Var. **variegàta,** Hort. (*H. maderénsis variegàta,* Hort.). Lvs. entire or slightly 3-lobed, edged yellowish white. G.C. II. 15:657. G.M. 54:320.

AA. *Pubescence scaly, golden yellow.*

cólchica, Koch (*H. Rægneriàna,* Hort. *H. coriàcea,* Hibberd). High-climbing: lvs. large, broadly ovate, cordate, almost entire, rarely slightly 3-lobed, bright green, of firm texture, those of flowering branches generally oblong-ovate: calyx-lobes triangular-ovate, conspicuous; calyx, pedicels and tips of young branches coated with golden yellow scales with about 20 or 25 rays: fr. black. Asia Minor, Caucasus, Persia. Gn. 25, p. 141; 34, p. 492. Gt. 11:360. Var. **dentàta,** Hibberd (*H. dentàta,* Hort.). Lvs. with remote small teeth, of somewhat thinner texture. G.M. 30:388; 54:318. Gn. 36, p. 7. Var. **purpùrea,** Hibberd. Lvs. purplish. Var. **arboréscens,** Koch. Not climbing, of upright shrubby habit. Gn. W. 20:467.

H. glomerulàta, DC., belongs to the genus Brassaiopsis and its correct name is B. glomerulata, Regel (B. speciosa, Decne. & Planch.). A glabrous tree, with large digitate lvs.; lfts. 5–7, oblong-lanceolate, stalked: fls. in long pendulous panicles consisting of long-stalked globular heads of small fls. S. Asia. B.M. 4804. Gt. 12:411. G.M. 32:367.—*H. himalàica,* Tobler (H. helix aurantiaca, André). High-climbing: pubescence scaly, gray or yellowish, the scales with many rays: lvs. of the sterile branches pinnately lobed with 2–5 lobes or teeth on each side, those of the flowering branches oblong-ovate to oblong-lanceolate, cuneate at the base: fr. yellow. Himalayas. R.H. 1884:84. Var. *sinénsis,* Tobler. Lvs. of sterile shoots entire or 3-lobed, of fertile branches elliptic or elliptic-oblong. W. China.—*H. japónica,* Tobler (H. helix var. rhombea, Sieb. & Zucc.). Not high-climbing: scales of pubescence with many rays: lvs. elliptic-ovate to rhombic-ovate, those of the sterile shoots 3- or rarely 5-lobed, with broad middle lobe and small lateral lobes: fr. black, about ⅓in. or less across. Japan, Korea.

ALFRED REHDER.

HEDGES. Living green fences are used for two distinct purposes—defense and ornament. Ornamental hedges may be rendered defensive by stretching tightly two or three strands of barbed wire through the center of the hedge. So far, no plant has yet been tested that meets all the requirements of the farmer for a truly impassable barrier, although the Osage orange (*Maclura pomifera*) possesses more recommendable features than any other hardy tree. This tree, however, is not hardy in the northernmost states. For regions south of Washington, D. C., Kentucky, and Missouri, *Poncirus* (or *Citrus*) *trifoliata* is of equal value. Both have the serious drawback of being subject to the attacks of the San José scale, but no satisfactory substitute has yet been found.

Next to these, perhaps, ranks the honey locust

(*Gleditsia triacanthos*), with many warm admirers and advocates. The hawthorn of Europe (*Cratægus Oxyacantha*) may not be planted in this country with much chance of success, owing to fungous enemies.

Cratægus Crus-galli is fairly satisfactory, but is not likely to make a tight hedge close to the ground. Other large thorny shrubs also fail in important particulars.

A perfect thorn hedge requires unremitting care, and must conform to an established rule, the most important being entire freedom from weeds and a systematic pruning. The preparation of the soil for a hedge consists of thoroughly plowing and cultivating an area 6 feet wide and the length the hedge is proposed to extend; or else to dig a trench 2 feet deep and 2 or 3 feet wide, and fill it with good top-soil thoroughly enriched. If this space should be fertilized and cropped the year previous growth will be greatly accelerated.

Deciduous plants must have the tops well shortened, and the root-tips of all plants should be given a clean cut, as they are planted. The plants should be set in a single row as close together as they can be set. For hedges a foot high or less, the plants should not be over 4 inches apart. For hedges 3 or 4 feet high, the plants should be 6 inches to a foot apart.

The double row, as formerly advised by some growers, is now practically obsolete and justly so, being difficult to cultivate and preserve free from weeds. The single row gives the plants a chance to be somewhat balanced, as the two opposite sides will have nearly equal freedom to develop.

A trench or furrow is opened through the center of the cultivated strip of a sufficient depth to admit the roots without bending. In setting, the soil must be made firm with the aid of a rammer, a practice unexcelled for aiding growth, and, indeed, preserving plant-life after removal. Pruning is simply an annual necessity from the first, excepting when the hedge is intended to be plashed, and even in such cases, after the laying process, pruning must never be omitted during summer. This work is greatly accelerated and consequently cheapened by shearing when the plants are young and tender, say during the month of July.

As to the best outline, a plain triangle, or what may be more sightly, the curvilinear or Gothic arch, is desirable, and a flat top is to be discouraged, as a body of snow lodged on it invariably injures the symmetry and beauty of any hedge. Another advantage of the triangular and Gothic arch types is that the sun can better reach the bottom of such hedges and keep them covered with foliage down to the ground. A rectangular hedge is liable to have bare spots at the base, while a hedge wider at the middle or top than at the bottom, is almost sure to be without foliage near the ground

Material available for defensive hedges has already been discussed. For ornamental hedges, there are a large number of plants available, both deciduous and evergreen. Of these the half-evergreen California privet (*Ligustrum ovalifolium*) is probably more largely used than anything else, and in the eastern United States possibly more largely used than all other material combined. Its advantage over its competitors is its low first cost, and its responsiveness to pruning and training. These are offset by its liability to kill to the ground every few years, even toward the South. Probably the best hedge plant, all things considered, is Thunberg's barberry (*Berberis Thunbergii*).

Of the evergreen hedges, the arbor-vitæ (*Thuya occidentalis*) is one of the most widely adaptable and deservedly popular. Hemlock (*Tsuga canadensis*) makes one of the handsomest but it succeeds in a comparatively restricted area. Its reputation as a slow grower should not prevent the box being more largely planted than it is. The Monterey cypress is much used as a hedge in California (Fig. 1790). There are many other evergreens that may be used to advantage.

Among the deciduous flowering plants are a great many that are desirable. A discussion of a few of these is included in the list that follows.

Where room at all permits, mass plantings or even untrimmed tree rows are better than a high hedge for barriers and screens. Plants with variegated or unusually colored foliage should be avoided for hedges.

The most serious annoyance to the hedge-grower is the presence of unwelcome woody vines, such as poison ivy (*Rhus Toxicodendron*), Japan evergreen honeysuckle (*Lonicera japonica*), and so on, and the only remedy is persistently to remove them by hand as soon as discovered. The attacks of insects may be treated similarly to those which injure other trees and shrubs.

Material especially adaptable for hedges.

Abelia grandiflora. Broad-leaved evergreen. Suitable for hedges up to 4 feet. Not hardy north of Washington and St. Louis.

Acer campestre. Deciduous. Adapted for hedges from 4 to 10 feet high in the northern half of the United States.

Azalea (*Rhododendron*) *amœna.* Evergreen. Good for hedges up to 2 feet. Good as far north as New York, Philadelphia, Cincinnati, and St. Louis. Attractive foliage and showy flowers.

Berberis Thunbergii. Deciduous, thorny, slow-growing. Cannot be relied on for hedges over 4 feet high. Adapted to all sections of the United States, except the non-irrigated arid regions. Responds to pruning, but makes a more attractive hedge when shears are not used. Naturally makes a tight bottom. Foliage small and most attractive. Bears annual crops of scarlet berries that hang on all winter, even in the South. Will grow within reach of salt-water spray. The best of the deciduous ornamental hedge plants, and has no superior in any class.

Berberis vulgaris. Deciduous, thorny. Useful for hedges from 3 to 6 feet high. Adapted to the northern half of the United States. Not so tight and compact as the foregoing. Bears berries that hang on half the winter. There is also a purple-leaved variety.

Buxus sempervirens (boxwood; tree box). The box of colonial gardens. Evergreen; slow-growing; adapted for hedges up to 20 feet. Thrives as far north as central New York, southern Ohio, and Missouri. Stands shearing well. Probably the best evergreen hedge-plant in the regions in which it grows.

Buxus suffruticosa (dwarf box). Evergreen. Suitable for use where a small hedge of the last-mentioned could be used.

Carpinus caroliniana (hornbeam). Deciduous. Good for hedges up to 10 feet. Makes a dense, strong hedge. Suitable for use as far south as Virginia and Kentucky.

Carpinus Betulus. Same adaptabilities as the last.

Chænomeles japonica (Japonica; Japan quince). Deciduous; somewhat spiny. Grows North and South and even in comparatively dry regions. Boy- and dog-proof, with handsome flowers. Somewhat subject to San José scale. Excellent.

Cinnamomum Camphora (camphor tree). Broad-leaved evergreen for high or low hedges. Hardy only near the coast from Charleston, South Carolina to Texas.

Cratægus Crus-galli (cockspur thorn). Deciduous. Has long spines. Can be used all over the country, except in the arid regions, but it is best adapted to the North. Flowers and fruits both attractive. Needs careful pruning when young to keep sides clothed to the ground.

Cratægus Oxyacantha. Similar to above. Not quite so dense a grower, but rather more showy flowers and fruits.

Deutzias. Deciduous, flowering shrubs of various heights from 30 inches to 6 feet, making rather loose hedges. Especially handsome when in flower. Some varieties hardy as far north as Chicago and northern New York; others only as far as St. Louis and New York City.

Elæagnus angustifolia. Deciduous. Adapted for hedges or low windbreaks to a height of 20 feet. Thrives in all parts of the United States. One of the best for the semi-arid regions. Summer fruits attractive.

1790. Monterey cypress hedge.

Elæagnus parvifolia. Deciduous. Similar to the preceding, but not so widely adaptable.

Evonymus japonica. Broad-leaved evergreen. Useful for hedges up to 3 or 4 feet at its northern limits and double that height in the South. Occasionally winterkills as far north as Philadelphia and Cincinnati but well adapted for regions farther south. There is a variety with yellow-edged leaves.

Fagus sylvatica (beech). Deciduous. Suitable for high hedges or screens. Thrives in the northern half of the country.

Gardenia jasminoides (Cape jessamine). Evergreen. Flowering. Used for hedges up to 5 feet. Hardy in South Carolina, Georgia and the states bordering on the Gulf of Mexico.

Gleditsia triacanthos (honey locust). Deciduous. Thorny. A good defensive hedge; succeeds over the whole United States. Especially valuable in the semi-arid regions and beyond the northern limits of the Osage orange (*Maclura maculata*).

Hibiscus syriacus (rose of Sharon). Deciduous. Flowering. Useful for hedges and screens under 10 feet where an open bottom is not objectionable. Will grow successfully except in the most northern tier of states. Transplant only in spring where the ground freezes in winter.

Ilex Aquifolium (English holly). Broad-leaved evergreen with spiny leaves. Useful for hedges from 2 to 6 feet. Desirable south of Philadelphia and St. Louis. There are many varieties. Handsome.

Ilex crenata (Japanese holly). Broad-leaved evergreen. Leaves smaller than either the preceding or following species and without spines on the leaves. Good for hedges not exceeding 4 feet. Hardy except in the extreme northern states.

Ilex opaca (American holly). Broad-leaved evergreen with spiny leaves. Useful for hedges and screens up to 30 feet. Native near the coast from New Jersey southward and along the Gulf of Mexico. Will grow inland on light soils and thrives on poor ground. Pistillate plants filled with scarlet berries all winter.

Juniperus virginiana (red cedar). Coniferous evergreen. Adapted for hedges and screens up to 30 feet. Thrives almost everywhere. There are several forms in cultivation, but the type is most suitable for hedges.

Ligustrum amurense (Amoor River privet). Broad-leaved evergreen. Leaves smaller than *L. Japonica* or *L. ovalifolium.* Better for hedges than *L. ovalifolium.* Hardy as far north as Virginia and Missouri.

Ligustrum Ibota. Deciduous. Adapted to hedges 10 feet and under. Hardy except in the most northern sections. Var. *Regelianum.* Dwarf. Makes hedges 4 feet and under. Filled with blue berries all winter.

Ligustrum japonicum. Broad-leaved evergreen. Useful for hedges up to 6 feet. Not reliably hardy as far north as Washington, D. C., and St. Louis.

Ligustrum ovalifolium (California privet). Broad-leaved half-evergreen shrub. Useful for hedges from 6 inches to 12 feet. Tops liable to freeze to the ground every few years as far south as North Carolina and Oklahoma. Rapid grower. Stands pruning well and needs it frequently. Ranks with dwarf box as a low edging for flower-beds, except it requires weekly or fortnightly pruning. Its low first cost has led to its use in many places where other plants would have been more attractive and more economical. Thrives near salt-water, even within reach of the spray.

Maclura pomifera (Osage orange). Deciduous. A defensive hedge. Hardy as far north as central New York and Nebraska. Subject to attacks of San José scale.

Osmanthus (Olea) fragrans (sweet olive). Broad-leaved evergreen, bearing sweet-scented flowers. Adapted to low hedges in the Gulf states and as far north as Wilmington, North Carolina, on the Atlantic coast.

Osmanthus Aquifolium. Broad-leaved evergreen. Much like *Ilex Aquifolium* in general appearance, but blooms in late summer. Has showy winter berries on pistillate plants. Sometimes winterkills as far north as Washington, D. C., and St. Louis.

Picea alba (white spruce). Coniferous evergreen. Formal in habit. Good for high hedges and screens. More pleasing in color than the next species. Good for the northern half of the country even in comparatively dry regions.

Picea excelsa (Norway spruce). Coniferous evergreen. Same adaptability as the last and more used than it, but not so desirable.

Pittosporum Tobira. Broad-leaved evergreen. Thrives in the South Atlantic and Gulf states.

Poncirus trifoliata (hardy orange). Almost evergreen South; deciduous in its northern range. Spiny. Good for defensive hedges from 3 to 10 feet high. Large glossy foliage. Attractive. Succeeds as far north as Philadelphia and Cincinnati. Subject to San José scale.

Populus nigra var. *fastigiata* (Lombardy poplar). Deciduous. Adapted for hedges and screens up to 30 feet. Useful in the northern half of the United States.

Prunus caroliniana (mock orange of the South). Broad-leaved evergreen adapted to the southern states from Norfolk south. Excellent.

Retinosporas. Coniferous evergreens adapted to hedges under 6 feet. Suitable for use south of the 40th parallel and in special localities north of it. Not suitable for the semi-arid regions.

Rhamnus cathartica. Deciduous. Good for hedges to 6 feet. Most useful in the northern half of the country.

Rosa rubiginosa (sweetbriar rose). Deciduous, thorny. Adapted for hedges up to 3½ feet. Thrives everywhere except in the most arid sections. It bears attractive flowers and hips, but does not make so close a hedge as many other plants.

Rosa rugosa. Deciduous, thorny. Adapted for hedges of 5 feet and under. Will grow both North and South and is promising for use in the semi-arid regions. Flowers and hips both attractive. For a summer hedge it is excellent, but its winter appearance is not hedge-like although quite effective as a deterrent to intruders.

Spiræas. Deciduous shrubs. A group of beautiful flowering shrubs adapted for use as low hedges North and South and promising for use in the semi-arid regions. *Spiræa Bumalda* var. *Anthony Waterer* would make a hedge 2 feet high with flat-topped pink blossoms in early summer. *Spiræa Thunbergii* grows 5 feet high with white flowers in early spring. It has fine foliage, but the tips of the branches are apt to winterkill even as far south as Virginia and Missouri. *Spiræa Van Houttei* is white, about intermediate between the other two in season. The finest of the spireas in flower. It has beautiful foliage and is adapted for hedges.

Syringas (lilacs). Deciduous shrubs. A group of beautiful flowering shrubs adapted to all parts of the United States, some species being especially promising for the semi-arid regions. *Syringa amurensis* is especially well adapted for use on the Great Plains. It grows 10 feet high. *Syringa persica* is about as adaptable as the last but more dwarf, growing but 5 feet high. *Syringa vulgaris* has many named varieties, both double and single, in a wide range of colors and habit of growth.

Thea Bohea (Chinese tea plant). Broad-leaved evergreen. Low-growing. Blooms in winter. Useful near the seacoast from Charleston, South Carolina, to Texas.

Thuya occidentalis (arbor-vitæ). A coniferous evergreen with many forms, of which the type is as useful as any for hedge purposes. Adapted to all sections of the United States. Much used and deservedly so.

Thuya orientalis (Chinese arbor-vitæ; Biota). Coniferous evergreen with many forms. Useful over nearly the same range as the foregoing.

Tsuga canadensis (hemlock). Coniferous evergreen. Useful for low and high hedges and screens to 50 feet. Adapted to moist and medium soils in the northern half of the United States. One of the handsomest in the regions in which it thrives.

Viburnums. Deciduous and evergreen shrubs. Many-berried and handsome. Among the desirable deciduous species that thrive all over the United States except in the extreme South and the drier regions are *V. cassinoides*, *V. dentatum*, *V. nudum*, *V. Opulus*, *V. plicatum*, and *V. prunifolium*. The handsome evergreen species *V. Tinus* is tender and not likely to succeed north of the Carolinas and the Gulf States, but where it succeeds it is most desirable.

F. L. MULFORD.

HEDRÆÁNTHUS, HEDRÁNTHUS: *Wahlenbergia.*

HEDÝCHIUM (Greek, *sweet snow;* the large white flowers are sweet-scented). *Zingiberàceæ.* BUTTERFLY LILY. GINGER LILY. GARLAND FLOWER. Leafy, rhizomatous herbs allied to Kæmpferia and ginger, grown under glass and in the open far South.

Flowers in a terminal spike or thyrse; calyx tubular, more or less 3-lobed at the summit; corolla-tube slender, scarcely longer than the calyx, all half concealed by the usually showy bracts; upper corolla-segm. often enlarged and lip-like; stamen 1, with a 2-loculed anther surrounding the style; staminodia always present, usually well developed.—Thirty-eight tropical species, Asian and one Madagascar. From the ginger Hedychium differs in having broad, almost petal-like staminodia, which in Zingiber is minute or lacking. The best botanical account is by K. Schumann in Engler's Pflanzenreich, hft. 20 (1904).

Hedychiums are strong-growing plants, very ornamental, both in foliage and in flower. They are essentially fall bloomers, although they may be made to bloom more or less continuously under glass. After blooming, gradually dry off the rhizomes, and let them rest for a time. Pot them up in spring or early summer, and give them rich soil and plenty of water and an occasional supply of liquid manure. The rhizomes may be divided every two or three years. They need an abundance of water. In fact, the pots may be set half their depth in water, and *H. coronarium* is often immersed until only the crown is emersed. The common white-flowered species is *H. coronarium.* This requires warmhouse treatment for best results, although it often flowers well when plunged in a warm, half-shady place in the open. The species do not stand frost, but they may be left out in the South if well protected. The flowers are very fragrant; in fact, their odor may be too heavy for a small room.

A. *Fls. white.*

coronàrium, Koenig. Three to 6 ft.: lvs. canna-like, green, pointed, smooth above, hairy beneath: fls. very large (3–4 in. across), long-tubed, pure white or the lip sometimes blotched green, the 3 outer segms. narrow, the lip large and erect and more or less lobed. Trop. Asia, and naturalized in some parts of Trop. Amer. B.M. 708. L.B.C. 6:507.—Handsome and worthy. Needs warm quarters. Said to have been sold as *Myrosma carnæfolia*, but that name belongs to a wholly different plant.

thyrsifórme, Hamilton. Usually 5 ft. tall: lf. sometimes 1 ft. long and 3–4 in. wide, finely hairy and pale beneath: spike very dense, the lower empty bracts ovate, the upper and fl.-bearing cylindric, green, about 1½ in.; corolla-tube not much longer than the bract, its segms. linear, white; lip distinctly clawed. Trop Himalaya. B. R. 767 (as *H. heteromallum*).—Not much known, but advertised (1914) by Montarioso Nursery.

AA. *Fls. yellow or red.*

B. *Infl. usually broader than long.*

flàvum, Roxbg. About 5 ft. tall: lvs. sessile, oblong, glabrous above, pale and hairy beneath: spike dense, the bracts broadly ovate or elliptic; fls. large, orange; corolla-tube cylindrical, 2½ in. long; segms. spreading, the outer ones linear and acute and an inch or so long, the lip very large and rounded, retuse; stamen not exserted. India. B.M. 3039 (and 2378?).

BB. *Infl. usually much longer than broad.*

Gardneriànum, Roscoe. Tall: lvs. sessile or the upper petioled: fls. light yellow, odd, short-stalked in the terminal spike, but the red filament long-projected beyond the segms.; lip oval and short, 3-toothed, the other segms. narrow: fr. red and showy. India. B. M. 6913. B.R. 774. J.H. III. 32:239 (in fruit). G.C. III. 11:176 (plate erroneously labeled *H. coronarium*); 46:126. G.W. 12, pp. 649, 650.—The best of the genus, and hardier than *H. coronarium.*

coccíneum, Buch.-Ham. St. about 6 ft. tall: lvs. all sessile, linear-lanceolate and sharp-pointed, glabrous above, glaucous beneath: fls. rather small, scarlet, the filament long-projected; lip nearly or quite entire; fl.-bracts conspicuous, acute or obtuse, triangular. India. L.B.C. 8:705.—A hybrid between this and *H. Gardnerianum* has been advertised as *H. Moòrei.*

H. Bousigoniànum, Pierre. A species from Cochin-China with sts. about 3 ft., with small bright green lvs. and about 18–25 pale yellow fls. and red anthers has been recently intro. It is scarcely known outside England. R.H. 1906:400.—*H. cárneum*, Carey. Fls. flesh-colored, scentless: height 3–4 ft.: lvs. over 1 ft. long, acuminate. E. Indies. B.M. 2637. L.B.C. 7:693.

N. TAYLOR.†

HEDÝSARUM (Greek for *sweet smell*). *Leguminòsæ.* Perhaps a dozen North American herbs, and about sixty in the Old World, sometimes planted for ornament.

Perennial herbs or subshrubs, with odd pinnate lvs., and often showy racemes of red, purple or white, small pea-like fls.: calyx 5-cleft, the teeth nearly equal and pointed; standard obcordate or obovate; keel nearly straight and longer than the wings; stamens 9 and 1: fr. a flattened jointed pod.—Very closely allied to Desmodium, but the latter genus has 3-foliolate lvs. Many of the hedysarums are attractive border plants. They are of easiest cult. in a light and open, well-drained soil. Give a sunny place; hardy. Prop. by division and seeds. For the sainfoin, sometimes known as *H. Onobrychis*, see *Onobrychis*.

A. *Fls. normally red (varying to white).*

coronàrium, Linn. FRENCH HONEYSUCKLE. Perennial or biennial, 2–4 ft. tall, branchy: an old garden plant with deep red, fragrant fls., crowded in axillary spikes or racemes: lvs. with 3–7 pairs of elliptic or roundish, somewhat pubescent lfts. Eu. Summer. Var. **álbum,** Hort., has white fls.—*H. hùmile*, Linn., is by some regarded as a form of this species, with rather more and narrower lfts., and wings only half as long as the keel.

AA. *Fls. normally purple (varying to white).*

multìjugum, Maxim. Hardy perennial of angular, straggling growth, 2–5 ft. high, very showy, and worthy of general cult.: fls. violet or purplish magenta, with yellow blotches, in racemes 8–18 in. long, all summer: lvs. 4–6 in. long, containing 6–12 pairs of grayish green oval, small lfts. Mongolia. Gn. 53:408. G.C. III. 18:8, 9. Excellent for rockwork. Var. **apiculàtum,** Sprague, has fewer lfts., which are apiculate, and glabrous above: perhaps the plant cult. as *H. multijugum.* B.M. 8091.

boreàle, Nutt. (*H. americànum*, Brit.). Erect or half-decumbent herb: sts. simple or nearly so, 1–3 ft.: lfts. 5–10 pairs, glabrous, oblong or oblanceolate: fls. violet-purple, varying to white, the calyx-teeth ovate-acute and shorter than the tube. Labrador and N. New England across the continent.

Mackénzii, Richards. Much like the last, but somewhat pubescent: fls. larger, violet-purple; calyx-teeth awl-like and acuminate, and longer than the tube, or at least equaling it: lfts. 5–9 pairs. Colo., north and west.

sibíricum, Poir. Height 3–4 ft.: lfts. ovate-lanceolate, glabrous, apiculate: fls. purple, drooping in long axillary racemes. Siberia. B.M. 2213 (as *H. alpinum*).

obscùrum, Linn. (*H. negléctum*, Ledeb.). Small, usually about 6–12 in. high: lfts. 5–9 pairs, ovate, glabrous: fls. purple, pendulous in long spikes. Eu. B.M. 282.—It is said to vary to white. L. H. B.

HEDYSCÈPE (Greek, *sweet covering*). *Palmàceæ*, tribe *Arèceæ*. UMBRELLA PALM. A tall hothouse palm known to the trade as a Kentia, and resembling that genus in habit and foliage, but distinct in flower. In Kentia the fls. are arranged in 4 ranks, and the ovule is fastened at the bottom of the cell, while in Hedyscepe (and its cult. allies, Kentiopsis, Veitchia, Nenga, Archontophœnix, Rhopalostylis and Dictyosperma) the fls. are spirally arranged in the branches of the spadix, and the ovule is fastened at the side. From the allies above mentioned Hedyscepe is distinguished by the following characters: staminate fls. with narrowly lanceolate sepals, 9–12 stamens, with long filaments; pistillate fls. with petals like the sepals and valvate at the apex. As a house plant, *H. Canterburyana* is dwarfer and more spreading than the two howeas, and has a lighter shade of green. G.C. II. 24:587.

H. Canterburyana, a very handsome palm, is the only species belonging to the genus, and, like the important howeas (or kentias of commercial horticulture), is known in a wild state only on Lord Howe's Island, where it is known as the "umbrella palm" from the recurving habit of its foliage. It grows at a greater altitude than the howeas, not appearing below the 900-feet level, and from this it may be inferred that a slightly lower temperature is more suitable for this palm; but in a general way the same conditions as those required by the so-called kentias will give good results with this subject, namely, a night temperature of 60° to 62° F., moderate shading throughout nearly the whole year, plenty of water, and a rich and rather heavy soil. These palms respond freely to generous treatment. As a commercial palm, *H. Canterburyana* is not very popular as yet, partly owing to the higher cost of seeds and the frequently low percentage of germination, and partly from the fact that in a young state this palm is by no means a rapid grower. In regard to hardiness of foliage, it is fully equal to the kentias, and for gracefulness and symmetry of growth will compare favorably with any of the commercial species. In southern California it is cultivated outdoors. (W. H. Taplin.)

1791. Hedyscepe Canterburyana.

Canterburyàna, Wendl. & Drude (*Kéntia Canterburyàna*, F. Muell. *Veìtchia Canterburyàna*, Hort.) UMBRELLA PALM. Fig. 1791 (adapted from Martius). Tall, spineless palm, with a thick, stout caudex: lvs. terminal, dense, equally pinnatisect, the numerous segms. linear-lanceolate, acuminate, the lower nerves recurved at the base, rather remote from the margin; rachis arched, recurving: spadix with a short peduncle, and thickened, flexuose branches; areoles lax: fls. medium: fr. ovoid, large. R.H. 1873, p. 218. F.R. 1:85. G. 2:418; 5:592; 16:414. G.W. 12, p. 207 (the last four all as Kentia). N. TAYLOR.†

HEÈRIA: *Heterocentron.* **H. elegans:** *Schizocentron.*

HEÌMIA (Geheimerath. Dr. Heim, Berlin, died 1834). *Lythràceæ*. Two shrubs of the New World, differing from Decodon in the yellow mostly 6-merous trimorphous fls. borne in spikes: stamens 10–18. **H. salicifòlia,** Link (*Nesæa salicifòlia*, HBK.), native from Mex. to Buenos Ayres, is offered abroad: subshrub, about 5 ft.: lvs. opposite or in 3's, or the upper alternate, lanceolate and acute: fls. yellow, with obovate petals. This is said to be prized as an antisyphiitic and for other purposes. L. H. B.

HELENIÓPSIS: *Heloniopsis.*

HELÈNIUM (possibly from Helenus, the son of Priam, but there is no clear record of the application of the name). *Compósitæ*. SNEEZEWEED. Hardy annual and perennial herbs, bearing yellow flowers from early summer to late autumn; only the perennials are in cultivation.

Stem erect, usually branching above: lvs. alternate, narrowly to broadly lanceolate, entire or toothed, glandular-dotted; the frequently decurrent petiole and st. sometimes winged: heads solitary or corymbose, yellow or brownish; disk-fls. perfect, fertile, their corollas 4–5-toothed; the ray-fls. pistillate or neutral, the rays wedge-shaped, 3–5-lobed.—About 30 species, N. Amer., Mex. Closely resembles Helianthus, but differs in having elongated, often top-shaped frs., which are never compressed and are usually silky villose; while the frs. of Helianthus are generally more or less 4-sided and are smooth. In Helenium the receptacle is naked; in Helianthus it bears paleaceous bracts.

Heleniums thrive best in a rich, moist soil, with a sunny aspect, and are propagated by seeds, cuttings or division. All the species are very easily grown, the only serious difficulty being a white aphis which sometimes attacks the roots. If plants look unhealthy they should be lifted, washed with an insecticide and reset in a new place. The commonest species in cult. is *H. autumnale*, but perhaps the most valuable species for general planting is *H. Hoopesii*, which is one of our earliest blooming composites, and is also desirable for the border or for cut-flowers. *H. Hoopesii*, *H. Bolanderi* and *H. autumnale* will give bloom in succession from May to October. The first two are also attractive when grown in pots, but they do not flower from seed the first year, either in pots or in the open.

A. *Heads rayless.*

aromáticum, Bailey, n. comb. (*Grahàmia aromática,* Hook. *Grahàmia aromática,* Spreng. *Cephalóphora aromática,* Schrad.). Erect, glaucous: st. herbaceous, much branched: lvs. alternate, linear-lanceolate, somewhat undulate and partially amplexicaul, the lower ones pinnatifid but the upper ones scarcely toothed: head discoid, terminating leafless branches; receptacle naked; florets yellow. Chile, in pastures and shrubby hills.—Offered abroad; fragrant. Listed in the trade as *Grahamia aromatica,* but all agree in referring Grahamia to Cephalophora; and Hoffmann now refers Cephalophora to Helenium. Whether the present species should really go under Helenium, is to be determined.

1792. Helenium autumnale. (×½)

AA. *Heads with rays.*

B. *St. and branches winged.*

C. *Disk yellow.*

autumnàle, Linn. (*H. grandiflòrum,* Nutt.). SNEEZEWEED. Fig. 1792. St. 2–6 ft. high, roughish, leafy: lvs. mostly toothed, smooth: heads 1–1½ in. across, numerous, borne at the end of short, very leafy stalks; rays drooping, 3-cleft, lemon-yellow to bright yellow; disk yellow. July–Oct. Moist places, Canada to Fla. and west to S. D., Kans. and Ala. B.M. 2994. Gn. 29:190; 55:218. A.G. 12:682. G.C. III. 10:433; III. 32:405.—Very showy. It has distinct merit for the back of borders, but is more appreciated in Eu. than in Amer. There are several garden forms: var. **pùmilum** is 1–2 ft. high, a very free bloomer, and is largely grown for cut-fls. in some places. J.H. III. 59:109. Var. **grandiflòrum** and var. **supérbum,** (*H. supérbum,* Hort.), are unusually vigorous and large-fld.; var. **striàtum,** has a maroon and gold disk, with yellow rays variously striped and splashed with rich crimson. J.H. III. 31:293. This should be distinguished from the striped forms of *H. nudiflorum.* Var. **grandicéphalum atropurpùreum** has almost entirely crimson fl.-heads. Var. **rùbrum** has deep red fls. A form known in the trade as *H. grandicephalum compactum bicolor* is also advertised. It seems to belong here.

CC. *Disk brown or purplish.*

D. *Lvs. all entire: heads solitary or few, long-stalked.*

Bígelovii, Gray. St. 2–3 ft. high, nearly smooth: upper lvs. narrow to oblong-lanceolate, lower spatulate: heads commonly 1½–2½ in. broad; rays ¾ in. long; fl.-stalk slender. Aug. Wet ground, Calif. S.H. 1:373.

Bolánderi, Gray. St. 1–2 ft. high, stout, somewhat pubescent: lvs. oblong to ovate-lanceolate, the lower obovate: heads commonly 3 in. wide; rays often 1 in. long; fl.-stalks thick, hollow. June–Sept. Low ground, N. E. Calif. Gn. 24, p. 157; 29, p. 191. R.H. 1891, p. 377.—Sometimes grown as *H. grandiflorum.*

DD. *Lower lvs. toothed: heads numerous, corymbose, short-stalked.*

nudiflòrum, Nutt. St. 1–3 ft. high, roughish, leafy: lower lvs. spatulate, toothed: heads 1–1½ in. across; rays wedge-shaped, drooping, yellow, brown-purple or striped with both colors. July–Oct. Moist soils, N. C. to Fla., west to Ill. and Texas.—A garden form, var. **grandicéphalum striàtum,** has fls. over 2 in. across. This form is also sold under the trade name *H. cupreum,* a name of no botanical significance.

BB. *St. and branches not winged.*

Hoòpesii, Gray (*Dugáldia Hoòpesii,* Rydb.). St. 1–3 ft. high, stout, slightly tomentose when young, but soon smooth, branching above into an umbel of several to many fls.: lvs. thickish, entire: heads usually borne singly on long stalks, commonly 3 in. wide; rays but slightly drooping; disk yellow. May–Sept. Rocky Mts.—A very fine border plant, and especially valuable for cut-fls.

H. Doùglasii, Hort.=Monolopia major.—*H. tenuifòlium,* Nutt. Annual. A weed in the S. Atlantic and southwestern states. St. 8 in. to 2 ft. high, very leafy: lvs. thread-like, entire, sessile, often whorled. Va., Fla., west to Mo. and Texas. B.M. 7721.

S. W. FLETCHER.
N. TAYLOR.†

HELEÓCHARIS: *Eleocharis.*

HELIAMPHÒRA (Greek compound, meaning *sun pitcher*). *Sarraceniàceæ.* One of the three genera comprising this singular family, consisting of a single species from the upper lands of British Guiana, and rarely grown in choice glasshouse collections.

Heliamphòra nùtans, Benth., is a perennial, 1–2 ft. high: lvs. all radical and pitcher-form; pitcher tubular and enlarging above, with a flaring open erect oblique mouth and a very small rudimentary lid terminating the midrib, hairy inside and winged down the front, in its native habitat conspicuously veined with red: fls. several on a slender scape, nodding, white or pale rose, each pedicel subtended by a prominent bract; perianth in 4–6 parts which are ovate-pointed; style straight, scarcely enlarging at the stigma. B.M. 7093. G.C. III. 37:194.—This unusual plant was first discovered in 1839 by the brothers Schomburgk, and was rediscovered in 1881 by Burke, an English orchid-collector who brought plants to England. It is a rhizomatous plant, and is prop. by single crowns. The plant is described as growing well in small pots in a mixture of peat, sphagnum and sand, surfaced with sphagnum, the pot plunged to the rim in moss and kept under a bell-glass. It requires much moisture. L. H. B.

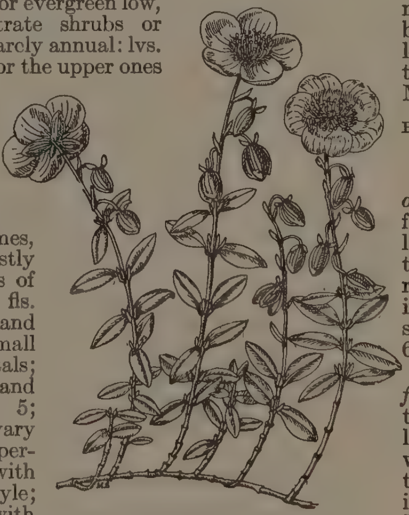
HELIANTHÉLLA (the plant resembles Helianthus). *Compósitæ.* Hardy perennial herbs from North America, with showy yellow heads borne in autumn.

Stem commonly unbranched: lvs. mostly scattered and sessile, linear or lanceolate, entire: heads solitary or few, with yellow infertile rays and a yellow or brownish disk.—Thirteen species. Helianthella belongs to a group of genera distinguished from Helianthus by having the frs. laterally compressed instead of thick and obtusely angled. Other cult. genera of this group are Actinomeris, Encelia and Verbesina, which are distinguished from one another by combinations of fr. and pappus characters.

The single species in cultivation is easily grown in a variety of soils, and is propagated by seeds or by dividing the rootstocks.

quinquenérvis, Gray. St. 2–4 ft. high, nearly smooth: lvs. mostly opposite, 4–9 in. long, the upper sessile: heads 3–5 in. broad, long-stalked, solitary or a few below in the axils of the lvs., with an involucre of large, leafy bracts; rays 15–20, pale yellow, 1½ in. long. June–Sept. Rocky Mts. S. W. Fletcher.

HELIÁNTHEMUM (Greek for *sun flower*). Including *Halímium, Tuberària* and *Fumàna. Cistàceæ.* Sun Rose. Ornamental woody or herbaceous plants grown chiefly for their showy flowers.



1793. Helianthemum Chamæcistus. (×¼)

Half-evergreen or evergreen low, upright or prostrate shrubs or perennial herbs, rarely annual: lvs. usually opposite, or the upper ones alternate, rarely all alternate, small, entire, with or without stipules: fls. in terminal racemose, umbellate or subcapitate cymes, rarely solitary, mostly yellow, sometimes of 2 kinds, earlier fls. with large petals and later fls. with small or without petals; sepals 3, or 5 and unequal; petals 5; stamens many; ovary 1-celled or imperfectly 3-celled, with slender or short style; caps. 3-valved with many or several seeds; embryo curved like a ring or hook (subgen. Halimium), or straight or folded (Helianthemum proper).—About 110 species in N. Amer. (and 3 in. S. Amer.), Eu., N. Afr. and W. Asia. Monograph by Grosser in Engler, Das Pflanzenreich, hft. 14. Cistaceæ, pp. 33–131 (1903); another important work is Sweet's Cistineæ (1825–30) where many species are figured, quoted below as S. C.

The helianthemums are mostly suffruticose or shrubby, less often herbaceous plants, either upright and low, or cespitose or prostrate, with small and usually narrow, often grayish foliage and with yellow or white, less often pink or red, usually profusely produced flowers in terminal racemes or clusters, rarely solitary, appearing during the summer and followed by a capsular fruit inclosed or surrounded by the persistent sepals; the flowers open only in the sun and the delicate petals soon drop. Most of the species are not hardy North without protection and are particularly suited to warmer and drier climates, but *H. Chamæcistus* is fairly hardy North, though in exposed situations it also profits by a protection of mulch: the hardiest of the species mentioned below is *H. canadense*, but it is at the same time the least attractive. They all thrive well in poor sandy or rocky soil, most of them being partial to limestone soil, and demand a sunny position to bloom profusely. They are especially adapted for rockeries and borders particularly the numerous forms of *H. Chamæcistus* which form dense mats; most of the other species are of low twiggy habit. Propagation is mostly by division, also by greenwood cuttings and by seeds which germinate readily, but if several species are grown together the seeds are liable to produce hybrids.

A. *Style short and straight, or almost wanting: lvs. without stipules.* (*Halimium.*)

B. *Fls. of 2 kinds, the larger solitary or rarely in 2's, the smaller apetalous ones clustered on lateral branchlets; sepals 5.*

1. **canadénse**, Michx. (*Halímium canadénse*, Grosser). Frostweed. Upright, 1–2 ft., hoary pubescent: lvs. nearly sessile, oblong to linear-lanceolate, acutish, pale beneath, ½–1⅓ in. long: the larger fls. 1 in. across, yellow; sepals 5, the outer linear, the inner ovate, tomentulose. June–Aug. Maine to Mich., south to N. C. and Miss.—Occasionally offered by dealers in native plants.

BB. *Fls. all large and showy, 1½–2 in. across; sepals 3.*

C. *Color of fls. yellow.*

2. **ocymoìdes**, Pers. (*H. algarvénse*, Dun. *Cístus algarvénsis*, Sims). Nearly erect, twiggy shrub, 2–3 ft., hoary-pubescent: lvs. short-petioled, oblong-lanceolate to oblong-spatulate, recurved at the apex, grayish, those of the flowering branchlets sessile, green, ¼–½, rarely to 1½ in. long: fls. yellow with purple eye, 1½ in. across, in loose, long-stalked corymbose clusters; sepals ovate-lanceolate. Spain and Portugal. B.M. 627, 5621. S.C. 40, and vars. 26, 65, 96.

3. **lasiánthum**, Pers. (*H. formòsum*, Dun. *Cístus formòsus*, Curtis). Spreading upright shrub, tomentose: lvs. short-stalked, oval to ovate-oblong or lanceolate, obtuse or acutish, often revolute on the margin, white-tomentose while young, ½–1 in. long: fls. yellow, the petals often spotted purple at the base, 2 in. across, in 1–5-fld. cymes; sepals ovate. Spain and Portugal. B.M. 264. S.C. 50. Gn. 26:420; 53, p. 131. G.M. 34:246. F.S.R. 2, p. 45. G. 16:382.—The most showy species of the genus.

CC. *Color of fls. white.*

4. **umbellàtum**, Mill. (*Cístus umbellàtus*, Linn.). Low shrub, upright or procumbent, 1–2 ft.: lvs. sessile, linear or linear-lanceolate, grayish tomentose beneath, pubescent above, later glabrescent, more or less viscid, ¾–1¼ in. long: fls. about 1 in. across, in whorls or racemose whorls; sepals ovate. Cent. S. Eu. N. Afr. S.C. 5.

AA. *Styles slender, often curved; sepals 5, the 2 outer ones smaller.* (*Helianthemum proper.*)

B. *Stipules subulate, the lower and middle ones about as long as petioles: fls. white or pink.*

5. **pilòsum**, Pers. Low nearly upright or ascending subshrub: lvs. short-petioled, linear or oblong, revolute,

grayish tomentose on both sides or green above, ⅓–¾in. long: fls. white, the petals with yellow blotch at the base, about 1 in. across, in 4–8-fld. cymes; outer sepals oblong or linear, inner ones broadly oval, ⅙–⅕in. long. S. W. Eu., N. Afr. S.C. 49.

6. **apennìnum,** Lam. (*H. polifòlium,* Pers.). Upright or procumbent subshrub, hoary-pubescent: lvs. petioled, elliptic to linear-oblong, grayish tomentose on both sides or green above, ⅓–¾, rarely to 1½ in. long: fls. white, the petals with yellow blotch at the base, 1 in. across in 3–10-fld. cymes; outer sepals linear-oblong, inner ones broadly oval, about ⅓in. long. W. and S. Eu., W. Asia. S.E.B. 2:159. S.C. 62. R.F.G. 3:33 (4554). Var. **ròseum,** Grosser (*H. rhodánthum,* Dun. *H. pulveruléntum* var. *ròseum,* Willk.). Lvs. lanceolate, acutish, ¾–1½ in. long: fls. over 1 in. across, pink to crimson. S.C. 7.

BB. *Stipules lanceolate or subulate, all longer than the petioles: fls. normally yellow, also white or pink.*

7. **Chamæcístus,** Mill. (*H. vulgàre,* Gärtn. *H. variábile,* Spach). Fig. 1793. Low procumbent subshrub, rarely upright: lvs. petioled, usually flat, ovate to linear-lanceolate, green on both sides, hairy or nearly glabrous, ½–1½ in. long: stipules lanceolate: fls. normally yellow, about 1 in. across, in many-fld loose racemes; outer sepals much shorter than the inner broadly oval ones. Eu., W. Asia., N. Afr. L.B.C. 3:202. R.F.G. 3:30 (4547, as var. *concolor*). G.W.H. 111.—This is an exceedingly variable species and numerous forms are cult. in European gardens; the following are perhaps the most noteworthy: Var. **grandiflòrum,** Fiek (*H. grandiflòrum,* Lam.). Lvs. ovate to oblong, green on both sides: fls. yellow, 1¼ in. long. Var. **cùpreum,** Grosser (*H. hyssopifòlium* var. *cùpreum,* Sweet). Lvs. oval to lanceolate, green on both sides: fls. copper-colored, darker toward the base, 1¼–1⅓ in. across. S.C. 58. Var. **tomentòsum,** Grosser (*H. tomentòsum,* Dun. *H. angustifòlium,* Pers. *H. polifòlium,* Hort.). Lvs. oblong to oblong-lanceolate, flat or revolute at the margin, white-tomentose beneath, ¼–¾in. long: fls. yellow. S.E.B. 2:158 and S.C. 34 (as *H. vulgare*). R.F.G. 3:30 (4547, as var. *discolor*). There is a double-fld. form, var. *tomentòsum múltiplex,* Grosser. S.C. 64. Var. **ròseum,** Grosser (*H. ròseum,* Sweet). Lvs. lanceolate, white-tomentose beneath: fls. pink, 1¼ in. across. A form with semi-double fls. is var. *ròseum múltiplex.* S.C. 86. Var. **venústum,** Grosser. Lvs. lanceolate, revolute, white-tomentose beneath: fls. crimson with yellow eye, over 1 in. across. S.C. 10. Var. **mutábile,** Grosser. Lvs. ovate-oblong, flat, grayish tomentose beneath: fls. at first light rose, changing to lilac, finally nearly white. S.C. 106. R.F.G. 3:35 (4556). Var. **stramíneum,** Grosser. Lvs. oval to oblong-lanceolate, flat, white-tomentose below: fls. bright straw-yellow, over 1 in. across. S.C. 93. There is a double-fld. form, var. *stramíneum múltiplex.* S.C. 94. Var. **diversifòlium,** Grosser. Lvs. oval to oblong- or linear-lanceolate, white-tomentose beneath: fls. purplish pink, the petals with a darker copper-colored blotch at the base. S.C. 95. A double-fld. form with purplish red fls. is var. *diversifòlium múltiplex.* S.C. 98. Var. **macránthum,** Grosser. Lvs. ovate-oblong, rather large, thinly grayish tomentose beneath: fls. white, nearly 1¾ in. across, the petals blotched yellow at the base. S.C. 103. There is a form with very double fls., var. *macránthum múltiplex.* S.C. 104.

8. **sulphùreum,** Willd. (*H. apenninum* × *H. Chamæcistus*). Procumbent sub-shrub: lvs. petioled, lanceolate, hairy on both sides, dark green above, grayish beneath, ½–¾in. long; stipules subulate: fls. sulfur-yellow, darker toward the base, about 1 in. across; the 2 outer sepals very small, narrow-lanceolate, the inner ovate. S.C. 37. There is a form with pink fls., var. **ròseum** (S.C. 51 as *H. canescens*), and one with copper-colored fls., var. **cùpreum** (S.C. 66).

H. alpéstre Dun. (H. oelandicum var. alpestre, Benth.). Cespitose subshrub: lvs. ovate-lanceolate to lanceolate, hairy or glabrescent, ½–¾in. long: fl. yellow, ½in. across. Mountains of S. Eu. S.C. 2.—*H. globulariæfòlium,* Pers. (Tuberaria globulariifolia, Willk.). Perennial; lvs. mostly radical, long-stalked, ovate, hairy, 1–2 in. long: fls. in simple or branched racemes, yellow with purple eye, 1¾ in. across. S. Eu., N. Afr. B.M. 4873 (as H. Tuberaria).—*H. lunulàtum,* Lam. Cespitose subshrub: lvs. elliptic-oblong, green on both sides, glabrescent or sparingly hairy, ⅓–½in. long: fls. solitary, yellow, ½in. across; petals with crescent-shaped spot at the base. Italy. R.F.G. 3:26 (4529).—*H. Tuberària,* Mill. (Tuberaria vulgaris, Willk.). Perennial: lvs. mostly radical, oval-lanceolate to obovate, grayish tomentose beneath, 1–3 in. long: fls. in simple or branched racemes, yellow, 1½ in. across. S. Eu., Afr. S.C. 18.—*H. Tuberària,* Hook. f.=H. globulariæfolium.

Alfred Rehder.

HELIÁNTHUS (Greek, *helios,* the sun, and *anthos,* a flower). *Compósitæ.* Including *Harpàlium.* Sunflower. Hardy herbaceous perennial and annual plants, rather coarse in habit, with yellow flowers which are mostly large, numerous and borne in autumn.

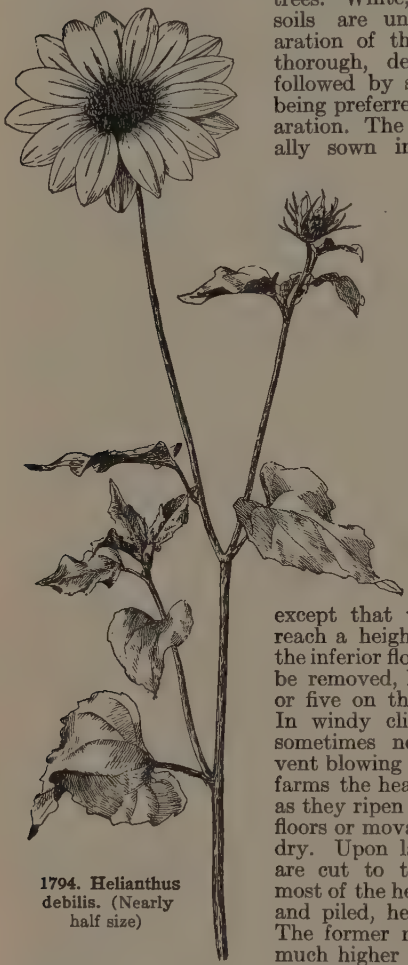
Leaves generally opposite below and alternate above, but this is not a constant character: heads pedunculate, solitary or corymbose, terminating the st. or branches; disk-fls. perfect, yellow, brown or purplish, with a tubular 5-limbed corolla; rays neutral, yellow.—Altogether there are about 60 species, mostly N. American, and many of the plants grown for sunflowers are now considered as belonging to other genera. The genus is very variable, and there are also many natural hybrids; hence the species are difficult to delimit. The old notion that the flower-heads follow the sun from east to west has been substantiated for *H. annuus.* (See Botanical Gazette, vol. 29:197.) Garden monographs are found in Gn. 27, p. 66; 45, p. 372; 49, p. 326 and 55, p. 146.

Sunflowers are of the easiest culture, and are adapted to a variety of soils. They are seen to best advantage when planted in masses, rather than as solitary specimens, and should be given plenty of room, being gross feeders. Most sunflowers, especially *H. annuus,* are too coarse to be harmonious near the house, but find an effective setting in the background, against the shrubbery border. A few species, however, especially *H. orgyalis* and *H. debilis,* are worth growing for their foliage alone. The annual species are propagated by seeds or cuttings; the perennial chiefly by division. All varieties of *H. multiflorus* root readily from both soft and hardwood cuttings. The double forms rarely produce fertile seeds and must be propagated by division. The seeds of annuals may be planted directly in the border, but it is best to start them indoors in March. Perennial kinds, particularly forms of *H. multiflorus,* should be taken up in late fall or early spring, every two years, and the rootstocks divided and replanted; otherwise the roots will ramble away, and the flowers will deteriorate. All thrive in a light, dry soil; but *H. annuus* and *H. giganteus* may be used to advantage for drying malarial spots. Sunflowers do not thrive in very shady places.

Commercial uses and cultivation of the common sunflower. (M. G. Kains).

Sunflowers (*H. annuus*) are cultivated extensively in Russia, India and Egypt; less widely in Turkey, Germany, Italy and France. The seeds from the large-seeded variety are sold upon the streets in Russia as we do peanuts, except that they are eaten raw. The small-seeded variety is preferred for the manufacture of oil. When cold-pressed, a citron-yellow sweet-tasting oil, considered equal to olive or almond oil for table use, is produced. The resulting oil-cake, when warm-pressed, yields a less edible fluid, which is used for lighting, and in such arts as woollen dressing, candle- and soap-making. The oils dry slowly, become turbid at ordinary temperatures and solid at 4° F. For stock and poultry feeding, and for other purposes, sunflower oil-cake is about equal in value to that of flax- and cotton-seed. The cake is largely exported by Russia to Denmark and

Sweden, and to some extent to other European markets. Sunflower stems and heads make an excellent paper, and the stems furnish a fine fiber that compares favorably with silk. They are, however, generally used for fuel, since the above industries have not been developed. —Sunflowers grow readily in many soils, but best results are secured upon light, rich, calcareous or alluvial land, well supplied with moisture and unshaded by trees. White, clayey and poor soils are unfavorable. Preparation of the soil should be thorough, deep fall plowing followed by spring harrowing being preferred to spring preparation. The seeds are generally sown in drills running north and south, 30 inches apart, 9 inches asunder in the drill, and 1 inch deep. Sometimes they are transplanted from nursery beds when 4 to 6 inches tall. About a week after the plants appear they are thinned to 18 inches apart. From four to six pounds of the seed will sow an acre. Cultivation is the same as for corn, except that when the plants reach a height of 3 to 4 feet, the inferior flower-heads should be removed, leaving only four or five on the principal stem. In windy climates hilling is sometimes necessary to prevent blowing down.—On some farms the heads are harvested as they ripen and placed upon floors or movable pole-racks to dry. Upon larger areas they are cut to the ground when most of the heads have ripened and piled, heads up, to cure. The former method insures a much higher grade of oil, and is therefore preferred. Every effort is made to prevent fermentation, either in the heads or in the pile of seeds, since this injures the quality of the oil. When thoroughly dry the heads are either placed on racks or piled, face downward, on a floor and beaten with flails. The seeds are then spread thinly, shoveled over occasionally, and allowed to become perfectly dry before being sent to the mill. The average yield is about fifty bushels to the acre. The percentage of husks ranges from 40 to 60; and the oil from 15 to 28. As a general rule, 100 bushels of seed will yield 33 bushels of kernels, 100 bushels of kernels from 280 to 320 gallons of oil of both qualities. Russian sunflower, a large-seeded variety, producing a single head, grows 8 feet tall, but is less esteemed for oil-production than the small-seeded varieties. In America the sunflower industry is small.



1794. Helianthus debilis. (Nearly half size)

The red sunflower. (T. D. A. Cockerell.)

In the summer of 1910 Mrs. Cockerell found a red sunflower growing by the roadside close to her home at Boulder, Colorado. It was a variation of the native sunflower of the plains (*Helianthus annuus* var. *lenticularis*, or *H. lenticularis*), having the rays suffused with chestnut-red. It was named var. *coronatus*, the arrangement of the red, with the black disk, suggesting the sun in eclipse, with its corona. Since the sunflower is sterile with its own pollen, it was necessary to cross the red one with yellow-rayed kinds, such as the garden *H. annuus*, and the yellow-rayed wild plant. The next summer, it was found that about half the progeny had red rays: it was determined that red was dominant, and assumed that the plant originally found was heterozygous for red, through variation occurring in a germ-cell. Crossing red with red, homozygous or pure-bred reds were obtained, with very rich colors. Most sunflowers carry a factor for marking, which affects the distribution of red, so that many of the flowers were bicolored with the ends of the rays yellow (var. *bicolor*) while others had a ring of red (var. *zonatus*). Some had the rays entirely chestnut-red (var. *ruberrimus*). A variety obtained in 1914 had the rays practically black. So far, the red of the red sunflowers was a chestnut, or brown-red. The pigment, however, belongs to the anthocyan group, and is chestnut only because seen on a background of orange. In order to obtain a new color, the homozygous red was crossed with Sutton's primrose variety (var. *primulinus*, Ckll., "Science," August 29, 1913, page 312). In the first generation (raised in the greenhouse during the winter) the flowers were all red on orange, or chestnut-red. These crossed together gave seventy-one chestnut-red, nineteen yellow, twenty-five wine-red and eight primrose; theoretical expectation, according to Mendel's law, being sixty-nine, twenty-three, twenty-three, and eight. The wine-red is due to the same anthocyan pigment, but on a primrose-yellow (pale yellow) background. In good examples, the color is nearly that known as "old rose." The various patterns are as in the chestnut-red forms. The wine-red sunflower was named var. *vinosus*. In addition to the above, various other varieties have been developed, including red and wine-red semi-doubles and doubles. There are also hybrids with *Helianthus cucumerifolius*, of relatively small stature and with shiny foliage. One of these hybrids, represented in the 1914 cultures by a number of plants, may be described as follows: About 4 feet high, spreading, much branched: stems speckled with purple: leaves dark green, very shiny, blades broad and short, strongly dentate: involucral bracts with long tapering ends (but not so long as in true *H. cucumerifolius*); disk small (about 1 inch diameter); rays ample, broad, numerous, with basal half rich chestnut, apical half bright lemon; disk very dark. This is a plant of the second generation from the original cross. For further details see "Popular Science Monthly," April 1912; "Science," August 29, 1913, pages 312, 313; August 21, 1914, pages 283–285, November 13, 1914, pages 708, 709 and January 1, 1915, pages 33, 34. "Garden Magazine," July, 1914. The red sunflower is now offered by the trade in America, England, Germany and Italy. It has also been grown successfully in Australia and New Zealand.

KEY TO THE SPECIES.

A. *Plants annual: lvs. long-petioled: disk brown or purplish.*
B. *St. erect, stout, simple or branching above.*
C. *Pubescence rough* .... 1. **annuus**
CC. *Pubescence usually silky* .... 2. **argophyllus**
BB. *St. diffuse, slender, branching freely from the base* .... 3. **debilis**
AA. *Plants perennial by creeping rootstocks: lvs. sessile or short-petioled.*
B. *Disk brown or purplish.*
C. *Lvs. linear, entire (except the lower), sessile.*
D. *St. rough* .... 4. **orgyalis**
DD. *St. usually smooth* .... 5. **angustifolius**
CC. *Lvs. ovate to broad-lanceolate, mostly toothed, narrowed at the base into a winged petiole.*
D. *Rays numerous, the fls. 2½–4 in. broad* .... 6. **scaberrimus**
DD. *Rays 10–16, about 1 in. long*.. 7. **atrorubens**
BB. *Disk yellowish.*
C. *St. smooth below, the branches often slightly rough or pubescent.*
D. *Foliage pale beneath.*
E. *Lvs. prevailingly lanceolate.*
F. *The lvs. glabrous on both sides* .... 8. **lævigatus**
FF. *The lvs. roughened beneath* .... 9. **grosse-serratus**
EE. *Lvs. prevailingly ovate*.....10. **strumosus**
DD. *Foliage green on both sides*
E. *Lvs. stalked*..............11. **decapetalus**
EE. *Lvs. sessile or nearly so*....12. **divaricatus**
CC. *St. rough or hairy below.*
D. *Rootstocks thickened into one or more fleshy tubers.*
E. *Lvs. prevailingly lanceolate.*
F. *The lvs. rough only above.*13. **giganteus**
FF. *The lvs. rough both sides.*.14. **Maximilianii**
EE. *Lvs. prevailingly ovate* .....15. **tuberosus**
DD. *Rootstocks all slender.*
E. *Lower lvs. sessile or with a clasping base.*
F. *Lvs. sessile*.............16. **doronicoides**
FF. *Lvs. cordate, clasping*....17. **mollis**
EE. *Lower lvs. short-petioled.*
F. *St. 1–2 ft., not branching*..18. **pumilus**
FF. *St. usually over 3 ft., branching.*
G. *The st. smooth and glabrous*...........19. **californicus**
GG. *The st. usually rough and hispid.*
H. *Foliage equally rough on both sides*......20. **lætiflorus**
HH. *Foliage rougher above than beneath.*
I. *The lvs. short-petioled*...........21. **hirsutus**
II. *The upper lvs. narrowed at the base.*22. **tracheliifolius**

1. **ánnuus,** Linn. COMMON SUNFLOWER. St. 3–12 ft., rough-hairy, often mottled: lvs. 4–12 in. long, broadly ovate, acute, the lower cordate, coarsely serrate, rough on both sides, 3-nerved: fls. 3–6 in. wide in wild specimens, often 14 in cult. July–Sept. Minn. to Texas, west to Wash. and Calif. Gn. 27, p. 68. Gt. 43, p. 95 and B.R. 1265 (as *H. lenticularis*).—A valuable economic and ornamental plant. The lvs. are used for fodder, the fls. yield a yellow dye, the seeds furnish an oil and are used for food. It is grown for food chiefly in Russia. *H. annuus* has long been in cult. as an ornamental, and has varied into many distinct forms. Common varieties are: Var. **califórnicus,** Hort., very large and double; var. **citrìnus,** Hort., with primrose-colored rays (Gn. 49, p. 327); var. **globòsus fistulòsus,** Hort., enormous globular heads (Gn. 27, p. 68); var. **nànus fl. pl.,** Hort., (Globe of Gold), dwarf and double, valuable for borders; **Russian Giant,** 10–12 ft. high, single, grown mostly for seed; var. **variegàtus,** Hort., with variegated lvs.

The *H. lenticulàris,* Douglas, is commonly referred to *H. annuus.* Cockerell supposes, however, that *H. lenticularis* is the wild species from which the cultivated forms of *H. annuus* are derived. Even so, *H. annuus,* being a Linnæan name, must stand. The many interesting mutations and hybrids observed and produced by Cockerell are based on the wild *H. annuus* (or *H. lenticularis*). Placing his variants under *H. lenticularis,* he names them as follows: Var. *bícolor,* Ckll., rays red, tipped yellow; var. *zonàtus,* Ckll., rays red-banded; var. *rubérrimus,* Ckll., rays chestnut-red throughout; var. *primùlinus,* Ckll., primrose-yellow; var. *vinòsus,* Ckll., rays wine-red; var. *vinossíssimus,* Ckll., rays entirely dark wine-red; var. *nìger,* Ckll., rays practically black above and slightly red at tip. This group of variants comprises the red sunflowers, now in cult. (See account also by Cockerell, page 1446.)

2. **argophýllus,** Torr. & Gray. SILVERY-LEAVED SUNFLOWER. St. usually solitary, 4–5 ft. high, soft gray, with a dense, silky pubescence, especially the upper branches. Otherwise like *H. annuus,* into which it seems to vary under cult. if the seedlings are not constantly selected for their silky character. Texas. The

1795. Clump of Helianthus orgyalis.

var. **texàna,** Hort., which does not differ botanically from the type, is an attractive form of this species. R.H. 1857, p. 431. Gn. 12, p. 280; 27, p. 67; 55, p. 147.

3. **débilis,** Nutt. (*H. cucumerifòlius*, Torr. & Gray). Cucumber-leaved Sunflower. Fig. 1794. St. 1–4 ft. high, usually several together, hairy throughout: branches often mottled with purple or white, each one bearing a fl.: lvs. 1–4 in. long, ovate to triangular, generally with a cordate base, thin, glossy, irregularly toothed or entire: fls. 2–3 in. wide, on slender peduncles. July–Sept. Fla. to Texas and westward. G.C. III. 17: 167. Gt. 44, p. 571. B.M. 7432. Gn. 49:326.—This is one of the best for cut-fls. It needs a sandy soil. Var. **plumòsus,** Hort. Disk-florets ligulate, from pale to deep yellow. Var. **purpùreus,** Hort. Ray-florets varying in color from light pink to deep purple.

1796. **Helianthus decapetalus var. multiflorus.**
(See species No. 11)

4. **orgyàlis,** DC. Fig. 1795. St. 8–10 ft. high, strict, smooth, very leafy to the top: lvs. 8–16 in. long, acuminate, slightly rough, drooping: fls. numerous, lemon-yellow. Sept., Oct. Dry plains, Neb. to Texas and westward. Gn. 27, p. 67; 55, p. 147. F.R. 2:146.—This species has distinct and attractive foliage, which is not at all coarse. A well-grown plant will produce spikes of fls. nearly 4 ft. long.

5. **angustifòlius,** Linn. Swamp Sunflower. St. 2–6 ft. high, simple or branching above, slightly rough: lvs. 2–7 in. long, somewhat tufted, drooping, in dried-up specimens with rolled edges, smooth or slightly rough: fls. 2–3 in. wide, few or solitary. Aug.–Oct. Wet land, N. Y. to Fla., west to Ky. and Texas. B.M. 2051.

6. **scabérrimus,** Ell. (*H. rígidus*, Desf. *H. missiouriénsis*, Schwein.). St. 1–3 ft. high (rarely 5–8 ft.), strict, sparingly branched, rough or hairy: lvs. 6–12 in. long, oblong to ovate-lanceolate, firm, thick, rough-hairy, entire or slightly toothed: fls. 2½–4 in. wide, showy, long-stalked; rays numerous, about 1½ in. long; disk sometimes yellow at first, turning brown. Aug.–Oct. Minn. to Ill., Ga., and Texas prairies. B.R. 508 (as *H. atrorubens*). B.M. 2020 (as *H. diffusus*); 2668 (as *H. atrorubens*). Gn. 27, p. 68. G. 3:391; 17: 544 (both as *Harpalium rigidum*).—After *H. decapetalus* this species is one of the best perennial sunflowers. It varies under cult. chiefly in the direction of doubling and in lengthening the blooming period. Some of the best garden varieties are **æstivàlis, grandiflòrus, semiplènus** and **Miss Mellish.**

7. **atrórubens,** Linn. (*H. sparsifòlius*, Hort.). Purple-disk Sunflower. St. 2–5 ft. high: lvs. usually thin, sometimes hoary beneath: fls. about 2 in. across; rays few (10–16), rarely over 1 in. long; disk dark red. Otherwise like *H. rigidus*, to which it is inferior. Va. to Fla., west to Ohio and La. G.M. 52:827 (as *H. sparsifolius*).—Suitable for dry shady places.

8. **lævigàtus,** Torr. & Gray. St. 2–5 ft., simple or branched above: lvs. 3–6 in. long, lanceolate, smooth, entire or slightly toothed: fls. 1–1½ in. broad, few or solitary; rays 6–10, usually less than 1 in. long. Aug.–Oct. Va. to N. C.

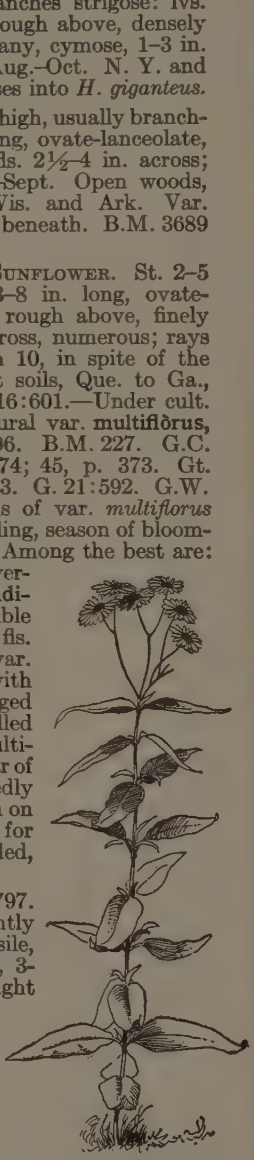
9. **gròsse-serràtus,** Mart. St. 6–10 ft. high, very smooth, glaucous, the smaller branches strigose: lvs. long-lanceolate, slender-petioled, rough above, densely hairy or canescent beneath: fls. many, cymose, 1–3 in. broad; rays 10–20, deep yellow. Aug.–Oct. N. Y. and Pa. to Mo., south to Texas.—Passes into *H. giganteus.*

10. **strumòsus,** Linn. St. 3–7 ft. high, usually branching, often glaucous: lvs. 3–8 in. long, ovate-lanceolate, rough above, entire or toothed: fls. 2½–4 in. across; rays 8–15, 1–1½ in. long. July–Sept. Open woods, Canada to Ga. and west to Wis. and Ark. Var. **macrophýllus,** Britt. Lvs. downy beneath. B.M. 3689 (as *H. mollis.*).

11. **decapétalus,** Linn. Wild Sunflower. St. 2–5 ft. high, branched above: lvs. 3–8 in. long, ovate-lanceolate, sharply serrate, thin, rough above, finely pubescent beneath: fls. 2–3 in. across, numerous; rays light yellow, generally more than 10, in spite of the specific name. July–Sept. Moist soils, Que. to Ga., west to Mich. and Ky. G.C. II. 16:601.—Under cult. it has given rise to the horticultural var. **multiflòrus,** (*H. multiflòrus*, Hort.). Fig. 1796. B.M. 227. G.C. III. 10:421. Gn. 27:66, pp. 71, 74; 45, p. 373. Gt. 43, p. 554. Gng. 3:83. F.R. 2:413. G. 21:592. G.W. 47:627.—The many garden forms of var. *multiflorus* differ mainly in the extent of doubling, season of blooming, habit of plant and size of fl. Among the best are: Var. **flòre-plèno** (sometimes advertised as var. **dùplex**) and var. **grandiflòrus,** almost completely double (G. 4:427; 11:231); var. **màjor,** fls. larger than common (G. 4:163); var. **máximus,** very large, single fls. with pointed rays; var. **símplex,** an alleged single form; **Soliel d'Or,** with quilled florets, like a cactus dahlia. Multiflorus varieties are the most popular of perennial sunflowers, and deservedly so. If the double forms are grown on poor soil, or are allowed to remain for several years without being divided, they become single.

12. **divaricàtus,** Linn. Fig. 1797. St. 1–6 ft. high, glabrous or slightly rough at the summit: lvs. sessile, rough above, pubescent beneath, 3-nerved, standing out nearly at right angles to the st.: fls. few or solitary, 2 in. across; rays 8–15. July–Sept. Dry woodlands, Canada to Fla., west to Neb. and La.

13. **gigantèus,** Linn. Indian Potato. St. 3–12 ft. high, stout: lvs. 3–7 in. long, lanceolate, very rough, serrate or nearly entire: fls. usually several, 1½–3 in.



1797. **Helianthus divaricatus.**

broad, mostly long-stalked; rays 10–20, barely 1 in. long, cupped, pale yellow: seeds smooth. Aug.–Oct. Wet ground, Canada to Fla., west to Neb. B.M. 7555. G.W. 2, p. 44; 7, p. 451; 8, p. 469. Var. **subtuberòsus,** Brit. A northern form with unusually fleshy roots, which were formerly collected by Indians for food; hence "Indian potato."

1798. Helianthus mollis var. cordatus.

14. **Maximílianii,** Schrad. St. generally 2–4 ft. high, sometimes 8–10: lvs. inclined to be trough-shaped: fls. on short, densely pubescent peduncles; rays 15–30, generally 1½ in. long, deep yellow. Otherwise like *H. giganteus*, of which it is probably the western form. Aug.–Oct. Dry plains, west of Mississippi River. V. 20:169.

15. **tuberòsus,** Linn. Jerusalem Artichoke. St. 5–12 ft., branched above: lvs. 4–8 in., usually ovate, acuminate, serrate, rough above, finely pubescent beneath: fls. several or numerous, 2–3 in. across; rays 12–20: seeds pubescent. Gn. 27, p. 68. B.M. 7545.—Frequently cult. for its edible tubers. See *Artichoke, Jerusalem.*

16. **doronicoìdes,** Lam. St. 3–7 ft. high: lvs. 4–8 in. long, ovate-oblong, narrowed toward both ends, rough on both sides, finely toothed: fls. numerous, in loose panicles; rays 12–20, broad. Otherwise as *H. lætifolius.* Aug., Sept. Dry soils, Ohio to Mich., Mo., and Ark. B.M. 2778 (as *H. pubescens*).

17. **móllis,** Lam. St. 2–5 ft. high, stout, very leafy, hoary villose, at least when young: lvs. 3–5 in. long, ovate-lanceolate, white-pubescent or rough on upper side: fls. solitary or few, 2–3 in. broad; rays 15–25. July–Sept. Barren soils, Ohio to Ga., west to Iowa and Texas; also on L. I. Gn. 55:146. Var. **cordàtus,** Fig. 1798, has recently been discovered. It has broader, thicker and cordate lvs. G.F. 2:137 (adapted in Fig. 1798).

18. **pùmilus,** Nutt. St. rough and hairy throughout: lvs. only 5–7 pairs, 1–4 in. long, ovate-lanceolate: heads few, short-peduncled; disk yellow. E. Rocky Mts. and adjacent plains.

19. **califórnicus,** DC. St. 3–8 ft. high: lvs. lanceolate, serrate, rough on both sides: fls. loosely paniculate, about 2½ in. wide. Calif.—Very suitable for low moist situations. Most of the plants grown under this name are garden forms of *H. annuus.*

20. **lætiflòrus,** Pers. Showy Sunflower. St. 4–8 ft. high, leafy and rough-hairy: lvs. 4–10 in. long, ovate-lanceolate, more or less serrate, rough on both sides: fls. several, 2–4 in. broad, short-peduncled; rays 15–25, about 1½ in. long, showy. Prairies, Ind., Ill., Wis. Gn. 45:372. G.M. 31:204.—A desirable helianthus. The garden form *H. semi-plenus* is better than the type. Resembles tall-growing forms of *H. rigidus*, but disk yellow.

21. **hirsùtus,** Raf. St. 2–4 ft. high, densely hairy: lvs. ovate-lanceolate, thick, very rough, pubescent and pale beneath: fls. several, 2–3 in. across; rays 12–15. July–Oct. Dry soils, Pa. to Ga., west to Wis. and Texas.

22. **tracheliifòlius,** Mill. Resembles *H. strumosus*, but st. and fl.-stalks usually rough-hairy and lvs. thinner, green on both sides: branches and fl.-stalks rough-hairy. Aug., Sept. Dry soil, Pa. to Wis.

H. ciliàris, DC. Fl.-heads large; rays bright golden-yellow; disk-florets dark brown. A pretty floriferous species. Texas, Ariz., Mex.—*H. coloradénsis*, Ckll. Allied to H. fascicularis and H. grosseserratus: 6 ft., in clumps: sts. strict, reddish and glaucous: lvs. elongate-lanceolate, rough, margins remotely dentate, the upper ones alternate and the lower opposite: bracts of involucre very long and slender, long-ciliate at base: disk yellow, and rays bright orange. Colorado. Var. *Andrèwsii*, Ckll. Rays deep orange, much richer in color.—*H. macrophýllus satìvus* of horticultural literature, with tubers edible and in taste resembling Jerusalem artichoke, is probably H. strumosus var. macrophyllus, Britt., or possibly H. giganteus var. subterosus, Britt. There are many forms of wild sunflower that may come into cult., through dealers in native plants. These should be sought in the regular manuals of botany. The genus allows of different botanical interpretations.

S. W. Fletcher.
N. Taylor.†

HELICHRỲSUM (Greek for *sun* and *gold;* referring to the flower-heads). Syn., *Elichrỳsum. Compósitæ.* Old World herbs or shrubs, mostly African and Australian; some of them are grown for everlastings, being, with Helipterum, amongst the most important plants for that purpose; annuals and perennials.

Flower-heads large, solitary, with fls. of 2 kinds, the outermost ones with pistils only; involucre dry and chaff-like, the stiff overlapping scales glabrous, often colored; heads large, terminating the branches, normally yellow, but now varying into many colors in long-cult. forms.—Probably 400 species. Easily grown as hardy annuals in any garden soil but doing best in a rich loamy soil. Very few are grown in U. S., except *H. bracteatum.*

A. *Lvs. oblong or narrow: grown for everlastings.*

B. *Heads large, solitary.*

bracteàtum, Andr. Fig. 1799. Stout annual, 1½–3 ft. tall, somewhat branched, the terete sts. nearly or quite glabrous: lvs. many and rather large, oblong-lanceolate, narrowed to a short petiole, entire, green: heads terminating the branches, 1–2½ in. across, yellow or orange, the short and obtuse involucre-scales imbricated. Austral.—Perhaps the most important single everlasting fl. grown in this country, particularly for bold or heavy design work. It is very variable, particularly in color. R.H. 1896:551. The heads are pure white in var. **álbum,** Hort. (*H. álbum*, Hort. *H. níveum*, Graham. B.M. 3857); scales tipped with red in var. **bícolor,** Hort. (*Elichrỳsum bícolor*, Lindl. B.R. 1814); dark scarlet in var. **atrococcíneum,** Hort. (*H. atrococcíneum*, Hort.); dark blood-red in var. **atrosanguíneum,** Hort. The forms with very large heads are often known as *H. macránthum*, Hort. The double forms are often known as *H. monstròsum*, Hort. Other portraits of this species will be found in B.R. 24:58. R.H. 1851:101.

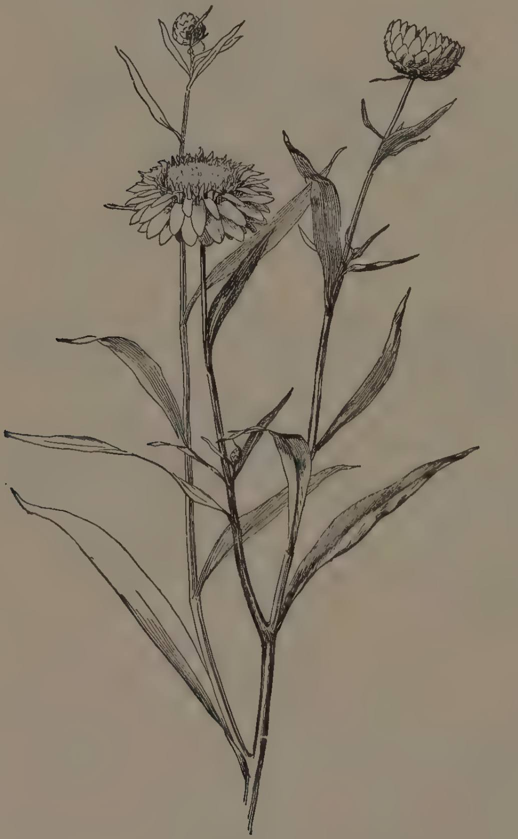
BB. *Heads medium to small, in clusters.*

C. *Color yellow or orange.*

arenàrium, DC. Yellow Everlasting. A foot or less high, herbaceous: lvs. plane, white-woolly, the lower ones oblong-obovate and long-attenuated into a petiole, the upper ones linear-lanceolate and acute: heads globular, in compact little corymbs, bright yellow. Perennial, in sand, France.—Apparently not cult. in this country. See *Everlastings*, p. 1183.

orientàle, Gaertn. (*Gnaphàlium orientàle*, Linn.). St. simple, 1½ ft. or less tall: lvs. oval-oblong to lanceolate, obtuse, sessile, rather small: heads bright yellow, small, globular, in corymbs. S. Eu. to Asia Minor. G. 1:805.—Much cult. in Medit. regions, but little known in this country.

apiculàtum, D. Don. Perennial, 1–2 ft., tomentose, leafy below: lvs. lance-spatulate, the base more or less spatulate: beads ½in. across, in small heads or clusters, orange-yellow, the scales sharp-pointed. Austral. —Little known in this country, and doubtfully hardy north of Philadelphia.



1799. Helichrysum bracteatum. One of the choicest everlastings. (×⅓)

CC. *Color white or nearly so.*

grandiflòrum, Less. Perennial, somewhat woody, decumbent at the base: lvs. crowded near the base, sessile, obovate to oval or oblong, obtuse, woolly on both sides: heads hemispherical, in corymbose clusters, glossy, cream-color, ¼in. across. S. Afr.—Greenhouse plant north of Washington.

diosmæfòlium, Sweet (*Ozothámnus rosmarinifòlius*, Hort.). Tall, upright: lvs. very small, narrow-linear (½in. or less long), the margins revolute: heads small and numerous, white. Austral., sometimes grows 20 ft. high. Gn. 34:409; 55:222.—Cult. in S. Calif. by Franceschi.

AA. *Lvs. ovate or broader: border and vase plants.*

bellidioìdes, Willd. Slender-stemmed, trailing, nearly woody perennial: lvs. light green above, woolly beneath, ovate-spatulate, ¼–½in. long, flat: heads solitary, about ½in. diam., of the "everlasting" type; receptacle convex or nearly conical. New Zeal. G.C. III. 53:266, 436. Gn. 77, p. 253. G. 35:341. G.M. 56:286. —Not common in cult. but useful as a prostrate perennial; not hardy N.

hùmile, Andr. (*Aphelèxis hùmilis*, Don). A low spreading, greenhouse perennial, with lvs. lacking tomentum, but sometimes woolly in the axils: lvs. round-backed, usually ⅛–¼in. long: scales of the involucre rosy. S. Afr.—A showy, but little-known species.

petiolàtum, DC. (*Gnaphàlium lanàtum*. Hort.). Tender perennial, cult. for its long, woolly sts. and woolly lvs., either as an edging in ribbon borders or as an ornament in lawn vases: lvs. petiolate, ovate and broad at the base, obtuse: heads (not often seen in cult.) in branched cymes, the involucre scales obtuse, cream-white. S. Afr.—An old garden plant. Prop. by cuttings from stock plants carried over winter.

H. Coòperi, Harvey. Bush with golden yellow fl.-heads. Afr.—*H. Guilélmii*, Engler. A robust perennial covered with white wool except the fl.-heads. E. Trop. Afr. B.M. 7789. Var. *Mèyeri*, G.C. III. 31, p. 4, note. Fls. arranged more loosely.—*H. Selàgo*, Benth. & Hook. f. Small, much-branched shrub: fl.-heads small, terminal, sessile, ¼in. across. New Zeal.—*H. Vólkensii*, O. Hoffm. Shrubby, with sts. and branches covered with white shaggy hairs: outer bracts bright rose, inner whitish and longer. E. Afr. G.C. III. 31:169, desc.

N. Taylor.†

HELICÒDEA: *Billbergia.*

HELICODÍCEROS (Greek, *spirally 2-horned*). *Aràceæ.* Odd spathe-bearing plant, from a tuber, sometimes grown as pot specimens; odor offensive.

The extraordinary plant shown in Fig. 1800 is known as the "hairy arum" and sold by the bulb-dealers as *Arum crinitum.* When in flower it has a disgusting odor which attracts carrion flies and bright green insects as uncanny as the plant itself. The plant is the only species in its genus, the hairiness of the spadix being a very distinct character. Helicodiceros and Dracunculus are alike in having few ovules, which are fastened at the top and bottom of the cell, but in the latter the staminate and pistillate fls. are close together, while in the former they are separated by a sterile portion. Arum differs from both genera in having the ovules fastened in 2 series at the side of the cell. The lvs. of Arum are spear- or arrow-shaped, while in the other two they are pedately cut.

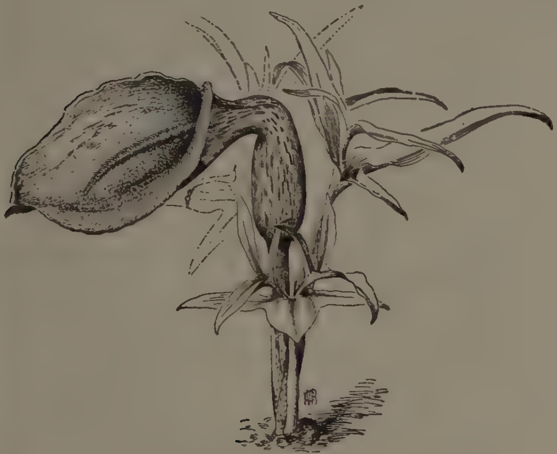
This plant is worth growing once, since it is one of the curiosities of horticulture. It may be secured from bulb-dealers in the autumn and flowered under glass in the spring. It is a most vile-smelling plant when in full flower. The plucky artist who drew the accompanying picture of this arum wrote at the bottom of his drawing, "Air 'em."

muscívorus, Engler (*H. crinìtus*, Schott. *Árum crinìtum*, Ait. *Dracúnculus crinìtus*, Schott.). Fig. 1800. Height 1½ ft.: spathe-limb purple, covered with purple hairs. Corsica. B.R. 831. F.S. 5:445. G. 11:585; 19:515.

Wilhelm Miller.

HELICÒNIA (Mt. Helicon, in Greece, seat of the Muses). *Musàceæ.* Foliage plants allied to Musa, grown in a warmhouse along with alocasias, anthuriums and calatheas.

From Musa, Heliconia differs chiefly in having a dry, often dehiscing, 3-loculed, 3-seeded fr.: fls. in clusters below the lvs., subtended by bracts after the way of Musa; sepals 3, linear, free or somewhat joined to the corolla; corolla short-tubed; stamens 5; staminodium 1: lvs. large and striking, often beautifully marked: sts. arising from a strong rootstock.—Perhaps 35 species in Trop. Amer., various of which have been intro. into cult., but the following are the only ones appearing in the American trade. Many species are being described from trop. Asia, and there is doubt about the American nativity of the genus. Some writers consider the Old World species as of the genus Heliconiopsis, which in the absence of evidence is not maintained here. For the botany of this very much perplexed genus, see Griggs, Bull. Torrey Club 20:640–664. Baker, Ann. Bot. 7:189–200. K. Schumann in Engler's Pflanzenreich, hft. 1 (1900). H. N. Ridley, G.C. III. 44:13.



1800. Helicodiceros muscivorus. (×⅛)

A. *Bracts of the infl. ovate-acuminate, deeply boat-shaped.*

Bihâi, Linn. (*H. caribǽa*, Lam.). Balisier. Wild Plantain. Becoming 10–15 ft. tall, banana-like: lvs. oval or oblong-oval, long-petioled, transversely ribbed, the blades 3–5 ft. long: blossom-sheaths very large, scarlet and black, the fls. red or orange. W. Indies and south. B.R. 374. L.B.C. 3:252.—A most striking plant, often seen in glasshouse collections. It is naturalized in the Old World tropics, and is the parent of many horticultural forms, of which the next two are almost surely examples.

aûreo-striàta, Bull. Perhaps a form of the preceding: lvs. beautifully striped along both midrib and transverse veins with golden yellow: sts. striped with yellow and green: lf.-limb oval-acuminate not decurrent: fr. ½in. long, obconic, orange. I.H. 29:464; 42, p. 289 (where a list of the best kinds will be found). S.H. 2, p. 133. F.R. 3:493. G.Z. 26, p. 123.—Very handsome. The best-known kind. Ridley considers this distinct from *H. Bihai*, but says he knows no native country for the species.

illústris, Bull. (*H. rùbro-striàta*, Hort.), is of the general style of the last, but the rib and veins are marked with pink and the lf.-bases are somewhat decurrent. Var. **rubricaûlis**, Hort., has more red, the petiole being bright vermilion; fr. red about ¼in. long. R.H. 1896:36 (where a review is made of the species). R.B. 21, p. 69. Gn. 52, p. 359. G. 20:369; 29:431. G.W. 2, p. 115; 7, p. 389.

AA. *Bracts of infl. lanceolate-acuminate, not boat-shaped.*

Michólitzii, Ridley. A very large plant forming large tufts: sts. 2 ft. or more tall, 3 in. across, pale green, marbled with gray: lvs. pale green, blade about 3 ft. long and about 1 ft. wide: infl. about 12 in. long on a hairy peduncle: rachis yellow, dotted with green: fls. 14 or more in each bract, the latter long-acuminate, white; sepals and petals acute, brownish; stamens slender, anthers linear: fr. orange, pear-shaped. New Ireland.—May not be a true Heliconia.

angustifòlia, Hook. (*H. bícolor*, Benth.). Dwarfer, whole plant not over 4 ft. tall: lvs. long and narrow, 1½–2½ ft. long, 3–6 in. wide, green: peduncle erect, glabrous; fls. yellowish green, 6–10 in each glabrous red bract. S. Amer. B.M. 4475.

H. insígnis, Hort., intro. by F. Sander & Son in 1912, is of uncertain botanical origin. It is described as "with dark bronzy-green lvs." and may be some form of H. metallica, Planch., which is described as dark shining green and purple beneath when young. B.M. 5315.—*H. Lêhmannii variegàta*, Hort., advertised by Royal Palm Nurseries, is of doubtful botanical position. It is described as "a stocky, broad-lvd. plant, somewhat resembling a miniature banana, with lvs. striped with creamy yellow, and having yellow sts."

N. Taylor.†

HELICOPHÝLLUM (*spiral leaf;* lateral segments of the pedatisect leaves sometimes twisted). *Aràceæ.* Nine or ten arisæma-like herbs of western Asia and delta of the Nile, of which one species may appear in collections; very little planted in the coolhouse, or in the open in mild climates with some protection.

Tuberous-rooted herbs, with radical lvs. and fls. appearing together: scape shorter than lvs., bearing a single inflorescence: spathe with an oblong tube and an erect or more or less hooded limb; spadix tailed, mostly included or short, the middle part with neutral fls.; apetalous; stamens 2; ovary 1, 1-celled, 2- or 4-ovuled: fr. an ovoid or globose berry. *H. Álberti*, Regel, is a stemless plant with a dark maroon-purple spathe 7 in. long: spadix 5 in. long, the appendix protruding and blackish purple: lvs. of young plants simple, oblong-lanceolate; of mature plants oddly divided, the "blade hastate, acuminate, undulate, concave at the base, with 2 lateral spreading horn-like horizontal basal lobes, and between them 2 long linear erect ones that are nearly as long as the blade, and face it; these front lobes have each on the outer margin below the middle a curved horn-like process." E. Bokhara. B.M. 6969. G.C. III. 36, suppl. Oct. 29.—Blooms in late spring, and requires protection.

L. H. B.

HELIOCÈREUS (*sun* and *cereus*). *Cactàceæ.* Procumbent plants with weak stems clambering over rocks and bushes.

Branches strongly angled: ribs usually 3 or 4, bearing clusters of spines from all the areoles: fls. diurnal, large and showy, with a short tube; petals elongated; stamens long and numerous, declined; ovary and fr. spiny.—The four species known all come from Mex. The species of this genus readily hybridize with species of Epiphyllum (Phyllocactus) and other related genera, giving rise to many horticultural varieties.

speciòsus, Brit. & Rose (*Cèreus speciòsus*, Cav.). Sts. freely branching at base, 1 in. diam., with a few aërial roots: spines in fascicles of 5–8, needle-like: fls. appearing from the older growth of the sts., 6 in. diam., remaining open for several days, purple-red: fr. 1½–2 in. long.

amecaénsis, Brit. & Rose (*Cèreus amecaénsis*, Heese). A recent introduction similar to the above, but with perfectly white fls. It is not common in this country, but is common in Eu.

J. N. Rose.

HELIÓPHILA (Greek, *sun-loving;* grows in the open country of the Cape). *Cruciferæ.* This genus includes a blue-flowered half-hardy annual that grows mostly a few inches high and is sometimes advertised in catalogues of flower seeds.

Heliophila contains about 80 species of annual and subshrubby perennials, natives of S. Afr. The transversely twice-folded cotyledons are an important character of the genus: other important generic characters are pods sessile or pedicelled, 2-celled, 2-valved, dehiscent: seeds in a single row, often winged: racemes long and leafless, and fls. yellow, white, rosy or sky-blue: lvs. various.

pilòsa, Lam. A very variable species, with st. 6–24 in. high, erect or diffuse, simple or unbranched from the base: lower lvs. often opposite, the rest alternate: fls. normally sky-blue, with a yellow center, but the natural varieties include lilac and yellow. The typical *H. pilosa* has a st. that is rough with spreading hairs: lvs. hairy, either oblong or linear, entire or sometimes lobed near apex, cuneate at base: pods linear, erect or spreading. Var. **incìsa**, Sonder, has lvs. linear-cuneate, 3-cut at the apex, rarely 5-cut, the lobes linear or acuminate. B.M. 496 (as *H. arabioides*). Wilhelm Miller.

HELIÓPSIS (Greek, *like the sun*). *Compósitæ.* Hardy herbaceous plants, bearing numerous yellow flowers in autumn.

Stem erect, loosely branching: heads yellow, long-stalked, borne in loose terminal or axillary panicles both radiate and discoid: lvs. opposite, petioled, 3-ribbed, oblong-ovate to ovate-lanceolate, coarsely toothed. Heliopsis has no pappus, while in Helianthus the pappus has 2 awns. In Heliopsis the rays have pistils, but may be fertile or sterile. In Helianthus the rays have no pistils at all.—About 10 species, all native of N. Amer. They are all perennials except one, and that is not cult. They are not common in gardens because of the more attractive forms in Helianthus. *H. helianthoides* var. *Pitcheriana*, however, deserves wider popularity. For cult., see *Helianthus*.

helianthoìdes, Sweet (*H. lævis*, Pers.). St. 3–5 ft. high: lvs. 3–5 in. long, thinnish, smooth on both sides or roughish above, opposite or sometimes in 3's: fls. numerous, 1½–2½ in. broad, long-stemmed. July–Oct. Open places, Canada to Fla., west to Ill. and Ky. B.M. 3372. Gn. 25, p. 237. Var. **Pitcheriàna** (*H. Pitcheriàna*, Hort.). A dwarf, more branching and bushy form, 2–3 ft. high, with a spread of 3–4 ft.: fls. produced much more freely than in the preceding and a deeper yellow. One of the best hardy plants for the perennial border, being especially valuable for cutting and for planting in dry places. A.G. 16:323. F.R. 2:259.

scàbra, Dunal. Differs from *H. helianthoìdes*, chiefly in being rough throughout: upper lvs. sometimes entire: heads few, often solitary. B.R. 592 (as *H. canescens*). Var. **gratíssima**, Hort. Fl.-heads large, brilliant pale yellow. Var. **imbricàta**, Hort. "A dwarf form with fls. 3 in. diam., golden yellow." Var. **màjor**, Hort. Larger in every way than the type. J.H. III. 33:359. Var. **zinniæflòra**, Hort. "A double form, there being several series of ligulate florets." R.H. 1908, p. 419. Dry soils, Maine to N. J. and west to Mo.

S. W. Fletcher.
N. Taylor †

HELIOTROPE: *Heliotropium.*

HELIOTRÒPIUM (heliotropic; *turning to the sun*). *Boraginàceæ.* Heliotrope. Popular glasshouse plants, prized for their flowers and fragrance.

Herbs or rarely shrubs, with small fls. in terminal, forking often scorpioid clusters and alternate simple lvs.: corolla short funnelform or salver-shape, the throat mostly open (sometimes constricted); stamens 5, attached to the tube, not exserted, the filaments very short; ovary 4-loculed and splitting into 4 nutlets (or two 2-loculed nutlets) when ripe, surmounted by a simple style.—Species upward of 250, in the warmer regions of the globe, many of them annuals. There is a heliotrope (*H. curassávicum*, Linn.) native to the U. S., from Del. and S. Ill. southward on seashores and in salty soils, with white or bluish fls. and oblong or linear lvs.; another species (*H. tenéllum*, Torr.) in open dry lands from Ky. to Kans. and southward, with white scattered or somewhat umbellate fls. and very narrow revolute lvs.; several species in the southern states and southward; also a naturalized species (*H. indicum*, Linn.) with bluish scented fls. and oval or ovate-rugose lvs.

The garden heliotropes seem to be derived from 2 species. **H. peruviànum**, Linn., is perhaps the leading species. Fig. 1801. Lvs. oval or oblong-lanceolate, very veiny, not conspicuously narrowed at the base: fls. small, in a close cyme, the corolla-tube little longer than the calyx. Peru. B.M. 141. G. 8:252. Vanilla-scented. *H. regale* is a garden race of this, with very large clusters and fls. of variable color. Gt. 50, p. 163. **H. corymbòsum**, Ruiz & Pav. (*H. grandiflòrum*, Don), has longer and relatively narrower lvs., which are distinctly narrowed to the base, fl.-clusters larger and more open, fls. nearly twice larger and the corolla-tube nearly twice longer than the calyx; calyx-teeth longer and narrower. Peru. B.M. 1609. Narcissus-scented. Many of the large-trussed and large-fld. garden varieties are apparently of this species rather than of the former; or possibility the two are hybridized. Originally both species were violet-fld. but the colors are now in various shades of purple, and there are white-fld. forms. **H. Voltaireànum**, Hort., is a compact garden form, and said to be a hybrid. P.M. 16: 100. Another species, **H. europæum**, Linn., is rarely seen in old collections, and it is sparingly naturalized. It is a hoary-downy annual herb 6–30 in. high, with long-petioled oval lvs., and white fls. in scirpioid racemes. **H. incànum**, Ruiz & Pav., of W. S. Amer., is perhaps in cult. as a greenhouse shrub: 2–3 ft.: lvs. thick, ovate, crenulate, more or less silky, hoary beneath: fls. white, in forking spikes, the corolla twice exceeding the calyx. Var. **glàbrum**, G.C. II. 22:809, has lvs. rough, nearly destitute of silky covering, broader and more ovate, a denser infl., a larger and more hairy calyx and purple fls. **H. anchusæfòlium**, Poir., of Brazil to Argentina, is said sometimes to be found in gardens and it is recorded as spontaneous in parts of this country; it is odorless: perennial, with 4-angled hispid st.: lvs. lanceolate to linear-lanceolate, sessile, entire: fls. violet, about ¼in. across. B.M. 8480.
L. H. B.

1801. Heliotropium peruvianum. (×½)

Heliotrope, apart from its use as a border plant and for bedding, being a universal favorite, usually forms part of the stock in trade of florists who do a local business, ranking next to the geranium as a pot-plant for spring trade. For cut-flowers in winter it is equally popular, but its lasting qualities when cut are uncertain. Successful growers think that for best results, strong stems and good keeping qualities, it should be grown in a moderately cool, airy house. Some of the best are grown in a house suited to violets and mignonette, where the temperature seldom rises to 50° F. at night.

Stout, soft cuttings make the best plants, and root easily in a temperature of 60° F. From the time they are inserted, sufficient water must be given to prevent wilting. A propagating-bed is not required. Ordinary flats will do—the medium half-leaf soil and sand. They must be well shaded for a week or so. They are very liable to the cutting-bench fungus, and should be potted or boxed off as soon as rooted, which should be in ten or twelve days. Any light soil will do, and it need not be rich for the first shift.

LII. Heliotrope, an old-time favorite.

For winter flowers, cuttings may be taken in July and treated as above. Some of the plants among the spring batch with straight stems may be grown along for standards by taking out the side shoots until 2 feet high. These make handsome drooping specimens. By pruning about midsummer they may be kept in good condition for years.

Heliotropes may be grown in the same pots for several years, by using fairly rich top-dressing or weak liquid manure in growing season.

Stock intended for spring cuttings is better grown continuously in pots, as the plants lift badly in the autumn. A few left-over bedding-plants may be grown along in pots, purposely for stock. As a matter of fact, stock taken from these pot-plants root more readily than those taken from plants grown outdoors. A good plan is to prune them rather closely a few weeks before the time for taking cuttings comes, say in January. In this way we secure an even lot of cuttings, and all at one time.

Heliotrope is extensively used as a bedding-plant, is a favorite in window-gardens, and is much grown by florists for cut-flowers. The ease with which it may be grown either in pots or the garden, the color and fragrance of its dainty flowers, and the continuity of bloom, have all contributed to make it a general favorite.

There have been numerous garden varieties and a number of hybrids—white and the different tints of blue predominating. Floral catalogues rarely mention, however, more than six to eight varieties. Madame de Blonay has been a favorite white for years, while Queen of Violets is perhaps the finest of the blues. Chieftain is a lighter tint. Albert Delaux is a variety with golden variegated foliage, but variegated heliotropes are undersirable. Among seedlings double forms occasionally appear. They have no special merit, and are seldom perpetuated. T. D. HATFIELD.

HELÍPTERUM (Greek for *sun* and *wing;* said to refer to the light-plumed pappus). Including *Acroclínium* and *Rhodánthe. Compósitæ.* Half-hardy annual or perennial herbs cultivated as everlastings or immortelles.

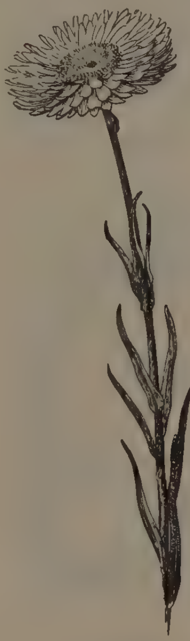
Flowers mostly perfect, with 5-toothed open corollas: achenes woolly, bearing a pappus of many plumose bristles: involucre glabrous, obovate or top-shaped, silvery or rose-colored: plants mostly glabrous.—About 60 species in Austral. and S. Afr. This and Helichrysum, from which it is distinguished by its plumose not roughened pappus-hairs, are amongst the most important of everlasting fls. The cult. kinds are annual herbs (or grown as such), of easiest cult. in any garden soil.

1802. Helipterum Manglesii. Generally known as Rhodanthe. (×⅓)

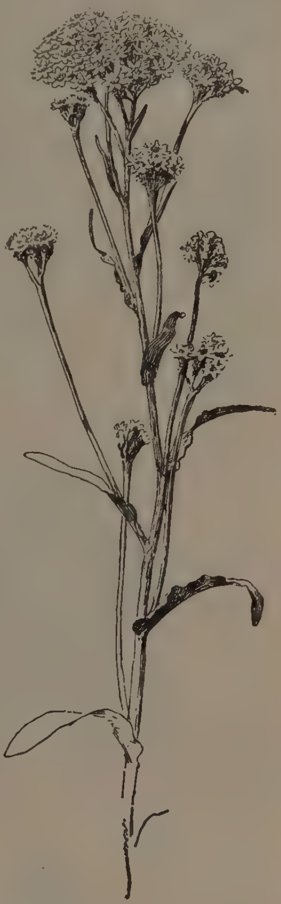
A. *Heads large, many-fld.*

B. *Lvs. broad.*

Mánglesii, Muell. (*Rhodánthe Mánglesii*, Lindl. *Roccárdia Mánglesii*, Voss). Fig. 1802. Neat glaucous annual, 12–18 in. tall, with very slender, long pedicels, bearing pretty nodding showy heads: lvs. thin, oval or elliptic, clasping: involucre silvery-chaffy, the ray-florets originally clear handsome pink, but now varying to white (*R. álba*, Hort.), and to dark red (*R. atrosanguínea*, Drumm.). R.H. 1852:141. Var. **maculàtum** (*R. maculàta*, Drumm. *Roccárdia Mánglesii* var. *maculàta*, Voss), is usually larger, with shorter lvs. and involucre flecked with red: rays pink or white. Austral. F.S. 22:2291. B. R. 1703.—A charming plant, and one of the few everlastings which retains much of its grace and beauty after being dried. There are double-fld. forms, i.e., those with all or nearly all the florets ligulate. Excellent also for pot culture. Seeds of the mixed varieties are sometimes sold under the name *Rhodanthe varius.*



1803. Helipterum roseum. (×½)



1804. Helipterum Humboldtianum. (×½)

BB. *Lvs. linear.*

ròseum, Benth. (*Acroclínium ròseum*, Hook. *Roccárdia ròsea*, Voss). Fig. 1803. Annual, 1–2 ft. high, glabrous, with many strict simple branches from the crown, each st. terminated by one large head: lvs. numerous, alternate, small and linear: rays many, pointed, bright pink (or varying to white in *H. álbum*, Hort.). Austral. B.M. 4801.—A serviceable plant.

AA. *Heads small, clustered.*

Humboldtiànum, DC. (*H. Sánfordii*, Hook. *Roccárdia Humboldtiàna*, Voss). Fig. 1804. Annual (or cult. as such), erect or with a decumbent base, the sts. somewhat branching: lvs. (and sts.) white-tomentose, at least when young, linear or lance-linear, pointed, alternate: heads small, oblong, yellow, in a dense terminal corymb. Austral. B.M. 5350. V. 3, p. 160.

corymbiflòrum, Schlecht. (*Roccárdia corymbiflòra*, Voss). Annual, lower than the last, more branchy: lvs. broader: heads 2–3 times larger, top-shaped, in small corymbs, the prominent rays white. Austral.

L. H. B.
N. TAYLOR.†

HELLÉBORUS (ancient name of *H. orientalis*, meaning unknown). *Ranunculàceæ.* HELLEBORE. Hardy herbaceous perennials, admired for their very early flowers and also their attractive leaves.

Erect, with large palmately divided lvs., the basal long-petioled, the upper sessile and sometimes reduced to bracts: fls. large, white, greenish, red, purple, or yellowish; sepals 5, broad, petal-like, mainly persistent; petals small, tubular, furnished with claws; stamens many: carpels 3–10, sessile, forming leathery, many-seeded caps., dehiscent at the apex.—About 8 species, natives of Eu. and W. Asia. Monographs by J. G. Baker in G.C. II. 7:432 (1877) and by Thos. Moore in G.C. II. 11:431 (1879).

All the kinds will thrive in ordinary garden soil, but for the best results use a soil of rich loam and coarse sand, with a top-dressing of rotten manure. A moist, well-drained, partially shaded situation is preferable. The species may be planted in shrubbery borders, and in rockeries, or if wanted for cut-flowers they should be planted in beds. An important point is not to disturb the plants when once established, as they are very sensitive to frequent changes of location. All the species bloom before spring arrives; a few mild days in December or January will bring out the buds and flowers of *H. niger* varieties, and the others are not far behind. White hellebore is not of this genus: see *Veratrum.*

1805. Christmas rose, Helleborus niger. (×1/3)

They are easily forced under glass. Strong plants should be taken up into large pots and gradually inured to a warm temperature. Blossoms may thus be brought forth at any time desired in winter. Propagation is best by division of roots in fall or spring. Gardeners prefer to divide the roots in late summer or fall, as this does not come at the flowering season. If seeds mature they will germinate well if planted immediately in boxes or in rich, open ground. Seedlings should bear flowers the third season.

A. *Lvs. dying annually, thin.*

víridis, Linn. St. scapose: rootstock creeping: 1 basal lf. 8–12 in. broad, on petiole 6–10 in. long; segms. 7–11, oblong, acute, sharply serrate: fl.-st. hardly exceeding the basal lf., bearing 3–6 fls. and large, lf.-like bracts: fls. large, yellowish green; sepals broadly oblong, obtuse, spreading: caps. about 4, as long as the sepals, transversely ribbed; style erect. Eu. Naturalized in eastern states. G.C. II. 25:553.—Not so much used as the other species here given. Var. **purpuráscens,** Waldst. & Kit. Differs chiefly in the central lf.-segms. being deeply palmately cleft, and the fls. much tinged with purple, especially on the outside. Hungary. B.M. 3170.

AA. *Lvs. evergreen, coriaceous.*

B. *Fl.-st. never more than once forked; fls. 1 or 2.*

nìger, Linn. CHRISTMAS ROSE. Fig. 1805. Stemless: rootstock short, black: only 1 lf. somewhat irregularly divided into lobes, toothed on the outer half; petiole 5–7 in. long: fl.-st. simple or once branched; fls. very large; sepals white, or flushed with purple: caps. 6–8. Rocky places, Eu. B.M. 8. Gn. 55, p. 13. J.H. III. 51:591; 61:583. G.W. 10, p. 245. Gn.M. 8:279. G. 27:534. C.L.A. 9:288. Var. **angustifòlius,** Hort. (var. *mìnor,* Hort.). Plant and lf. similar, but fls. small. Very pretty. G.C. II. 21:85, and III. 21:19. G.M. 50:933. G.W. 2, p. 230. Gn.W. 23:45. Var. **altifòlius,** Hayne (var. *màjor,* Hort. Var. *máximus,* Hort.). Petiole reaching 1 ft. long: fls. the largest in the genus, 3–5 in. across, and often several on same st. Gn. 14:178; 48:6. G.C. II. 20:693. A.G. 11:63; 21:41. G. 1:657; 8:537; 11:395; 6:367; Var. **præcox,** Hort. Fls. smaller than in type, from Sept. to Feb.

BB. *Fl.-st. forked 2 or 3 times; fls. several or many.*

C. *Without lvs. on st. below infl.*

orientàlis, Lam. Stemless; short creeping rootstock: 1 radical lf., 7–9-lobed; segms. 6 in. long, 1½–2 in. broad, acute, serrate in the outer half, pubescent, with strongly raised veins beneath; petiole 1 ft. long: fl.-st. over 1 ft. high, forked above, 2–6-fld., large, lf.-like bracts; sepals roundish, imbricated, white, purple beneath and purple edges, spreading: caps. oblong, shorter than the sepals, transversely ribbed; style erect or incurved. Asia Minor. Gn. 47, p. 136. G. 18:79.—There are numerous varieties of this beautiful species.

Purple-fld. varieties of H. orientalis.

Var. **cólchicus,** Regel. St. purple-spotted, quite glaucous: 1 lf. to each fl.-st.: fls. 3–6 on a st., deep bright purple, both inside and out. Asia Minor. B.M. 4581. J.F. 2, pl. 140 (both as *H. atrorubens*). Gt. 1860:293. Var. **cólchicus-punctàtus,** Moore. Fls. deeper plum-purple, more glaucous, exquisitely mottled inside with innumerable dark dots. Gn. 16:60, f. 8.—One of the handsomest of all the hellebores.

Var. **abchásicus,** A. Braun. Much like var. *Colchicus,* but differing in having 2 or more lvs. to a fl.-st. Caucasus region. Gt. 1866:496 (as *H. caucasicus* var. *abchasicus,* Regel).

Var. **atrórubens,** Waldst. & Kit. Only 1 lf. on a fl.-st. glabrous, thinner in texture than in the rest of the orientalis group: segms. narrow: fls. 2–4 on a st.; sepals dark purple outside, greenish purple within. Hungary. R.H. 1865:231.—A connecting link between the viridis and orientalis groups.

Var. **rùbro-purpùreus,** Hort. (*H. atropurpùrea,* Hort.). A seedling of var. *atrorubens,* with bold foliage and purple fl.-sts.: fls. spreading, deep purple. Characters well fixed and very handsome. Gn. 16:60, f. 1. R.H. 1884:564.

Purple-fld. hybrids of the varieties of *H. orientalis* are found in the trade under the following names: Var. *elegans;* var. *iridescens; F. C. Heinemann,* fls. very large, imbricated, deep purple and mottled; *Frau Irene Heinemann,* fls. rose-purple outside, greenish white, with dark lines and dots inside; *Gretchen Heinemann,* red-fld., strong grower; *Hofgarten-Inspector Hartwig,* fls. rose-purple without and greenish within; *Apotheker Bogren,* rose-purple, very large.

White-fld. varieties of H. orientalis.

Var. **olýmpicus,** Lindl. Glabrous: fls. small, but spreading, very numerous; sepals green on outer surface, white within. Bithynia. B.R. 28:58.—Hybrids closely allied to this have been given the trade names: Willy Schmidt and Prof. Dr. Schleicher.

Var. **guttàtus,** A. Braun. Glabrous, green st.: sepals green outside, white within and elegantly spotted with purple-crimson dots. Caucasus region.—Two allied hybrid forms are named: Commerz Benary and Albin Otto. Gn. 16:60, f. 4. G.M. 54:73.

Var. **antiquòrum,** A. Braun. Glabrous, green mottled st.: fls. as in var. *olympicus,* but more imbricated, maintaining the bell-shaped form. B.R. 28:34 (as *H. orientalis,* Lindl.). Gn. 16:60, f. 3.

Green-fld. variety of H. orientalis.

Var. **caucásicus,** A. Braun. Lvs. very glossy; segms. more oblong than in the type, often 3 or 4 in. broad: sepals round, pale green, much imbricated. Caucasus region. G.M. 51:873. Gn.W. 24:44.

cc. *With lvs. on st. below infl.*

fœtidus, Linn. True st. 1 ft. high, marked with lf.-scars near the base: lvs. coriaceous, with petioles 3–6 in. long: fl.-st. branched low down; sepals green or bordered with bright purple, under 1 in. long, stamens of same length. Fls. in late winter and early spring. W. Eu.

H. córsicus, Willd. (H. lividus, Auth.). Lvs. trifoliate, dirty yellowish green in color; lfts. broad-ovate, sharply toothed on margins. Blooms March to April. Corsica, Sardinia.—*H. lividus,* Ait. Under cult. a robust plant with thick, fleshy sts.: radical lvs. simple, cordate; cauline trifoliate: fls. 2½ in. across, dull purple-gray, tinged with green, nodding, in panicles of 6–8. Balearic Isls. B.M. 72;7903. G. 27:422.

K. C. Davis.

HELÒNIAS (Greek, referring to swamp). *Liliàceæ.* Swamp-Pink. Stud-Pink. A hardy perennial bulbous plant in wet places from northern New Jersey to North Carolina and is sold by dealers in native plants for bog-gardening.

Rootstock stout and tuberous: scape hollow, bracted, bearing at the top a short dense spike of rather showy purple fls.: segms. 6, persistent; stamens 6: caps. obovoid, 3-lobed, dehiscent above.—One species.

bullàta, Linn. Lvs. several or numerous, thin, dark green, clustered at the base of the scape, 6–15 in. long, ½–2 in. wide, with fine parallel nerves: scape stout, bracted below: in very early spring it bears a hollow scape 1–2 ft. high, crowned by a raceme 1–3 in. long, composed of perhaps 30 pink or purplish fls., each ½ in. across, 6-lobed, and with 6 blue anthers. B.M. 747. L.B.C. 10:961. B.B. 1:402.—Helonias, which is perfectly hardy, is so easily prop. by division that it is hardly worth while to grow from seed. Under cult., also, it seems rarely to mature perfect seed. It multiplies itself rapidly from offsets, a single plant often providing a dozen others in a season. It is found growing in dense shade and also in the full glare of the sun, always in wet sphagnum bog in the latter case, while in the shade it sometimes spreads to dry ground. Although one of the showiest of all American bog-plants, it is comparatively little known here, though better in England. It makes an elegant pot-plant.

Harlan P. Kelsey.
Wilhelm Miller.

HELONIÓPSIS (Greek, *like Helonias*). *Liliàceæ.* Herbaceous plants resembling the swamp-pink, *Helonias bullata,* in the color of flowers, but the flowers are larger and fewer, and the leaves numerous and tufted.

Scapose plants, with fls. few in a raceme or sometimes solitary: style a conspicuous feature, being long and red, tipped with a purple undivided stigma, while in Helonias the style is very short and 3-cut. Both genera are separated from numerous allied genera by the septicidal dehiscence of their caps. The fls. are bell-shaped, drooping, deep pink, 6-lobed, with 6 red filaments and purple-blue stamens.—The genus has about 4 species in Japan and Formosa.

japónica, Maxim. Rootstock short, stout, with long root-fibers: lvs. oblanceolate, persistent, green tinged brown or purple: fls. pink or rose-colored, on rather long pedicels, in few-fld. racemes: seeds small, very numerous, with a conspicuous tail at each end. Japan. B.M. 6986.—It grows in the mountains of Japan at an altitude of 2,000–7,000 ft., and is presumably hardy.

breviscàpa, Maxim. (*H. grandiflòra,* Franch. & Sav.). Rootstock præmorse, thick and short: radical lvs. spatulate, acuminate; scape-lvs. short: pedicels very short; perianth blush-white, the segms. obovate; style and stamens scarcely exserted: seeds appendaged. Japan. G.C. III. 37:178. Gn. 68:52.—Recommended in England for early spring bloom and hardy; requires a damp and shady position.—Entire plant 6–8 in. high.

H. umbellàta, Baker, from Formosa, has oblanceolate mucronate lvs., st. 3–5 in. high, and 3–10 fls. in an umbel, the segms. obtuse and scarcely 1 line wide.

L. H. B.

HELWÍNGIA (after G. A. Helwing, 1666–1748, a German clergyman, who wrote on the botany of Prussia). *Araliàceæ.* A curious deciduous shrub, remarkable for the reason that the small, inconspicuous greenish flowers are borne in clusters on the midribs of the leaves at about the center of their upper surfaces.

Flowers diœcious, short-pedicelled, with obsolete calyx, 3–5 petals and stamens and 3–4-celled ovary: fr. a berry-like, 3–4-seeded drupe.—Two species in Japan and Himalayas. Of not much decorative value and therefore rarely cult., but interesting on account of the unusual position of the fls.; hardy as far north as Boston. It seems to grow in any soil that is somewhat moist. Prop. by greenwood cuttings under glass.

japónica, Dietr. (*H. rusciflòra,* Willd.). Bushy shrub, 3–5 ft. high: lvs. petioled, ovate or elliptic-ovate, acuminate, serrate, stipulate, 1½–3 in. long: fls. in June, the staminate generally with 3, the pistillate with 4 petals. Japan. S.Z. 86. A.G. 13:8.

A. Phelps Wyman.

HELXÌNE (from the Greek to *tear,* because the seeds catch on the clothes). *Urticàceæ.* A small creeping herb with filamentous branches: lvs. alternate, small, entire, roundish: fls. monœcious, pistillate in the axils of the lower lvs., staminate in axils of upper. One species, *H. Soleiròlii,* Req., from Corsica and Sardinia. Sts. slender, reddish: lvs. bright green, cordate-reniform: fls. inconspicuous.—A good plant for the alpine garden, to be grown in moderate shade.

HEMEROCÁLLIS (Greek, *beautiful for a day;* because the blossoms fail at night). *Liliàceæ.* Yellow Day Lily. Popular yellow- and orange-flowered stout-rooted glabrous perennials with abundant radical foliage, prized for their hardiness and the showy bloom in spring and summer.

Erect with more or less branching scapes overtopping the long keeled lvs. which are both radical and 2-ranked at the base of the scape: fls. lily-like, mostly horizontal or oblique; tube short, inclosing the ovary; segms. 6, much exceeding the tube, oblong or spatulate; stamens 6, inserted in the throat, declined, the filaments slender, the style simple; ovary oblong, 3-celled, becoming a loculicidally 3-valved caps.: seeds black, spherical.—Species about a half-dozen, Eu. to Japan.

Hemerocallis includes the lemon lily (*H. flava*), one of the hardiest and best of herbaceous perennials. All the blue and white day lilies belong to the genus Hosta; all the yellow and orange day lilies belong to Hemerocallis. The yellow day lilies have narrow, grass-like foliage, and their flowers have wider funnels; the blue and white day lilies have very broad foliage, which is not at all grass-like. The plants are all remarkably free from enemies, and need no protection of any kind, even in the severest winters. The roots are bundles of fleshy tubers, and are sometimes classed with bulbs in catalogues of nurserymen. Small plants will bloom the first year from the nursery. Clumps can often be left undivided for four or five years without loss in size or number of flowers, but as a general thing all robust-growing herbaceous perennials should be divided frequently. In old clumps the roots often become firmly matted near the middle, and the wasteful competition between the too-numerous roots weakens the vitality of the plant and the flowers are likely not to be good. Next to *H. flava*, the oldest garden favorites among the yellow day lillies is *H. fulva*, sometimes called brown day lily, and erroneously in some catalogues the lemon lily. *H. fulva* is a taller plant, with later and orange-colored flowers and wavy inner segments. *H. aurantiaca* has come into prominence, and its var. *major* by some connoisseurs is considered the finest of all day lilies. As a rule, double forms are not so popular as the types, and they lack the simplicity and definite character of the single flowers. Yellow day lilies have a wholesome fragrance. The individual flowers are short-lived, but there is a good succession. The plants thrive in almost any garden soil, but are most luxuriant along the borders of ponds or moist places, and in partial shade. The flowers are excellent for cutting. Plants propagated by division. R. B. Whyte gives the succession of bloom at Ottawa, Canada, as follows: *H. Dumortierii*, June 4; *H. minor*, *H. Middendorfii* and *H. Thunbergii*, June 11; *H. rutilans*, June 18; *H. fulva*, July 2; *H. aurantiaca* var. *major*, July 9; *H. fulva* var. *Kwanso*, July 23, and *H. disticha fl.-pl.*, July 30. The common species, particularly *H. fulva*, often colonize about yards, and along roadsides, sometimes making great areas of foliage and very little bloom. There are several worthy hybrids in cultivation in the choice collections of plants (see supplementary list).

1806. Hemerocallis flava.

A. *Group of yellow-fld. species: fragrant.*

1. **flàva**, Linn. LEMON LILY. Fig. 1806. Lvs. 18–24 in. long, 6–8 lines wide: scapes longer than the lvs.; corymb 6–9-fld.; pedicels 12–24 lines long; tube 6–15 lines long. Eu., Temp. Asia. B.M. 19. A.G. 17:437; 24:363. Gn. 48, p. 400. G.W. 8, p. 277.—Blooms in June in the N. U. S.

2. **Thúnbergii**, Baker. Except for its later flowering, according to Baker, this species does not differ materially from *H. flava:* lvs. 6–7½ lines wide: corymb loose, 8–10-fld., with 1 or 2 fls. lower down; tube nearly 1 in. long; fls. lemon-yellow, opening widely, 3 in. across; segms. membranous, crisped. Japan. Intro. 1890.—Said to differ from all others in having the upper 6–10 in. of the scape thickened and flattened.

3. **lutèola**, Hort. Hybrid of *H. aurantiaca* var. *major* × *H. Thunbergii:* fls. golden-yellow, 6 in. across, on stout branching sts. 4 ft. high. Midway between parents in habit and in size of bloom. G. 25:346.—Raised at Colchester Nurseries, England. There is a var. **màjor,** Hort., large. Var. **pállens,** Hort., is a hybrid between *H. citrina* and *H. luteola:* vigorous, many-fld.: fls. large, fragrant, canary-yellow.

4. **Míddendorffii,** Traut. & Mey. Height 1–1½ ft.: lvs. 15–18 in. long, 8–12 lines wide: scapes about as long as the lvs.; corymb 2–4-fld.; pedicels almost none; tube 5–6 lines long; inner segms. 9–12 lines wide. Amur region. Gt. 522. R.H. 1897, p. 139.

5. **citrìna,** Baroni. Fls. lemon-yellow or pale sulfur-yellow: differs from *H. minor* in the lvs. being twice as broad and the fls. much larger; from *H. Dumortierii* in having a longer scape and lvs. three times as long, and fls. twice the size and longer-tubed. China.—Tall-growing, very fragrant; considered to be a fine species; excellent for cutting.

6. **mìnor,** Mill. (*H. gramínea,* Andr., not Schlecht. *H. graminifòlia,* Schlecht.) Fls. golden-yellow: lvs. 15–18 in. long, 2–3 lines wide, darker green than in the other species: scapes about as long as the lvs.; corymb 3–6-fld.; pedicels 3–24 lines long; inner segms. membranous and wavy at the margin. July, Aug. N. and E. Asia. B.M. 873. Var. **cròcea,** Hort., is saffron-yellow.

AA. *Group of orange-fld. species: the last not fragrant.*

7. **Dumortièrii,** Morren (*H. rùtilans,* Hort. *H. Sièboldii,* Hort.). Height 1½–2 ft.: lvs. 12–15 in. long, 6–8 lines wide: scapes hardly as long as the lvs.; corymb 2–3-fld.; pedicels 3–6 lines long; fls. 2–2½ in. long, while they are 3–4 in. long in the other species; inner segms. 5–6 lines wide; tube very short. Japan. B.H. 2:43. Gn. 31:280. Var. **flòre-plèno** is less cult.—This species is the earliest to blossom. This species is confused; some authors consider it to be a form of *H. minor.*

8. **aurantìaca,** Baker. Height 2½–3 ft.: lvs. more than 12 lines wide: corymb 6–8-fld.; fls. bright orange, opening less widely than any other species, fragrant. July. Japan or E. Siberia (?).—The type was intro. to cult. in 1890 and has rapidly given way to var. **màjor,** Baker, intro. 1895, which is larger in all parts. Lvs. 12–18 lines wide: tube 9 lines long; fls. when expanded 5–6 in. across. July–Sept. Japan. G.C. III. 18:71. Gn. 48:400; 50, p. 17. J.H. III. 31:157. A.G. 18:179.—Closest to *H. Dumortierii,* from which it is chiefly distinguished by its much larger, later and more reddish fls. with longer tube.

9. **fúlva,** Linn. (*H. dísticha,* Donn). Lvs. 18–24 in. long, 9–15 lines wide: corymb 6–12-fld.; fls. orange; pedicels short; inner segms. with wavy margins, with numerous veins joined by cross veins. July, Aug. Eu., Temp. Asia. B.M. 64 (central band of white). Mn. 5, p. 193. Var. **Kwánso,** Hort. (*H. Kwánso,* Hort.), the "double orange lily," blooms longer than any single-fld. form. Gt. 500. It has a sub-variety with variegated lvs. Var. **maculàta,** Baroni. Fls. with a red-purple blotch inside. China. Var. **longitùba,** Hort. Perianth-tube half as long as segms. Gt. 34:1187. Japan. Var. **flòre-plèno,** Hort., is shown in F.S. 18:1891, with a red spot on the middle of each segm. Gn. 48, p. 401. R.H. 1897, p. 139. Var. **variegàta,** has a stripe of white down the middle of each lf. Var. **hupehénsis,** Hort. Fls. very bright coppery red, with yellow throat; segms. undulate, reflexed. China. Var. **Cypriàni,** Hort. Dwarfer and more floriferous than the type: fls. coppery red with golden center and a golden line in the middle of the segms. China.

H. Baròni, Hort. (H. Thunbergii × H. citrina). Pale yellow; segms. narrow and pointed.—*H. coròna,* Hort. (H. flava × H. aurantiaca var. major). Floriferous, golden yellow.—*H. elménsis,* Hort. (H. minor and H. citrina).—*H. Flórham* is said to be a variety of American origin, with large golden yellow fragrant fls. in June and July. *H. Fórrestii,* Diels, recently intro. from W. China, is allied to H. fulva, but readily distinguished by its narrow perianth which has a remarkably short tube: fls. deep reddish orange: lvs. 8–14 in. long and ⅔ in. or less broad.—*H. fulcitrìna,* Hort. (H. fulva var. maculata and H. citrina).—*H. hippeastroìdes,* Hort. (H. minor var. crocea and H. Thunbergii.)—*H. Muèlleri,* Hort. (H. Thunbergii and H. citrina).—*H. ochroleùca,* Hort. (H. Thunbergii and H. citrina). Pale primrose-yellow.—*H. vomerénsis,* Hort. (H. Thunbergii and H. minor var. crocea).

WILHELM MILLER.
L. H. B.†

HEMIÁNDRA (*half anther* or *male,* referring to the 1-celled anthers). *Labiàtæ.* Three shrubs or subshrubs in W. Austral., with opposite, rigid and narrow entire sharp-pointed lvs., and solitary axillary white or pink fls.: corolla with a short erect broadly 2-lobed upper lip, and a longer spreading 3-lobed lower lip with the middle lobe often 2-lobed; stamens 4, didynamous; style briefly 2-lobed, *H. púngens,* R. Br., is recorded in European horticultural literature: rigid shrub, 1–2 ft. or less, glabrous or nearly so: lvs. sessile, linear or linear-lanceolate, with 1 or 2 prominent veins beneath: fls. white or pink with darker spots; corolla-tube exserted and dilated. J.F. 2:126.—Mentioned as a greenhouse subshrub.

L. H B.

HEMICỲCLIA (Greek, *semi-circular,* referring to the seed-scar or the half-circular stigma). *Euphorbiàceæ.* Shrubs or trees, one cultivated in southern California for its holly-like leaves and red fruits.

Leaves alternate, simple, entire, leathery: fls. diœcious, in axillary clusters or the pistillate singly; sepals of the staminate fls. 4–5, imbricate, sometimes somewhat petal-like, petals none; stamens numerous from a disk; stigma sessile, broad, flat; 2 ovules in the single cell: fr. a 1-seeded, indehiscent drupe.—About 9 species of E. Indies to Austral. Related to Drypetes and Putranjiva. *H. australasica* is distinguished from the other 2 Australian species by its very short filaments and glabrous ovary.

australàsica, Muell. Arg. Lvs. broadly ovate to ovate-oblong, obtuse, 1½–3 in. long, finely veined below: fr. nearly ½in. long, very smooth, red and succulent, inclosing a stone.

J. B. S. NORTON.

HEMÍGRAPHIS (*half written,* of some obscure or fanciful application). *Acanthàceæ.* Diffuse or prostrate, mostly herbs, grown for foliage and fls. The genus, comprising perhaps 30 species in Trop. Asia, China, Japan and the Philippines, is allied to Strobilanthes and more remotely to Ruellia. From the former it is distinguished by the 3–∞ ovules in each cell, linear caps. with base scarcely constricted, and in the prostrate or trailing habit. Fls. in short terminal crowded spikes, the bracts usually herbaceous and imbricated; calyx deeply 5-cut; corolla slender-tubed with 5 rounded more or less unequal lobes; stamens 4, didynamous: lvs. opposite, simple, entire or dentate. **H. coloràta,** Hallier (*Ruèllia coloràta,* Blume; once listed as *Amaglyptus*), from Java, is a name listed in S. Fla., as a good subject for baskets and for cover: lvs. of *H. colorata* are ovate, shallowly cordate at base, crenate and bullate, purplish: fls. white or whitish, about ¾in. long. There is likely to be confusion in the trade plants in this and related groups.

L. H. B.

HEMIONÌTIS (Greek, *mule;* the plants erroneously supposed to be sterile). *Polypodiàceæ.* A group of small tropical ferns, with copiously netted veins and naked lines of sporangia following the veins. Eight or 9 species occur in the tropics of both hemispheres. The plants are dwarf, and are grown in Wardian cases by a few fanciers in the Old World. For cult., see *Ferns.*

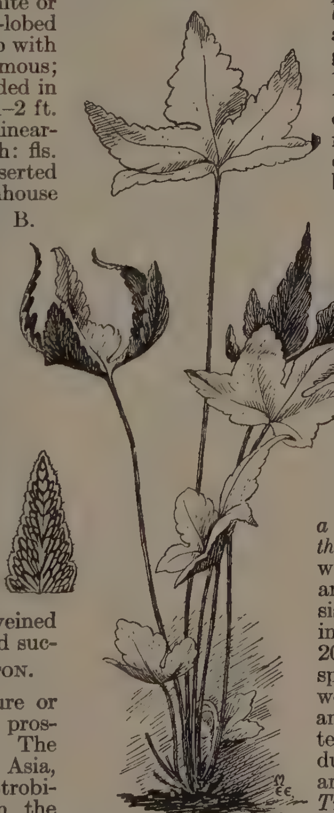
palmàta, Linn. STRAWBERRY FERN. Fig. 1807. Lf.-blades borne on tall stalks, palmate, 2–6 in. wide, with 5 nearly equal triangular divisions, those of the sterile lvs. less acute; surfaces pubescent. Reproduces by numerous buds as well as by spores. W. Indies, Mex., S. Amer.

élegans, Davenp. Lvs. 4–10 in. wide, with a broad sinus at the base and 5 long slender, lanceolate divisions: plant smooth. Mex. G.F. 4:485.

L. M. UNDERWOOD.
R. C. BENEDICT.†

HEMIPHRÁGMA (*half partition,* referring to structure of the capsule). *Scrophulariàceæ.* One trailing perennial herb, *H. heterophýllum,* Wall., sometimes grown abroad for rockwork and ground-cover, requiring protection in England. It is prostrate, with wiry branches, pilose or becoming glabrous: lvs. on main st. opposite, petiolate, orbicular and crenate; on branches small and fascicled, linear and ciliate: fls. sessile in the axils, small, pink; calyx 5-parted, with linear segms.; corolla-tube short, the limb 5-lobed and nearly equal; stamens 4: fr. a fleshy caps. or berry, shining, red. Himalaya region.

L. H. B.



1807. Hemionitis palmata. (×½)

HEMIPTÈLIA: *Zelkova.*

HEMITÈLIA (Greek, *with half a roof;* referring to sori). *Cyatheàceæ.* Tree ferns of the tropics, with round or semiglobose sori and an inferior indusium, consisting of a scale which is often indistinct and deciduous. Some 20 species occur in both hemispheres. This genus is not very well distinguished from Cyathea and Alsophila, differing only in technical characters of the indusium. For cult., see *Cyathea* and *Alsophila;* also article on *Tree ferns,* under *Ferns.*

guianénsis, Hook. Rachis slightly scaly and hispid: lvs.

bi-tripinnate, the secondary rachis distinctly winged, especially at the upper portion: sori few in each segm., usually 2–4; indusium ciliate and often lobed. Var. **Paràdæ,** Hort., is the form commonly in cult. British Guiana. I.H. 24:280.

Líndenii, Hook. Lvs. pinnate, the pinnæ distant and slightly stalked, 6–12 in. long, 1–1¼ in. broad, the base truncate or wedge-shaped: sori in 2–3 irregular lines near the margin. Venezuela. I.H. 42:46.

L. M. UNDERWOOD.
R. C. BENEDICT.†

HEMLOCK in Old World literature is what is known as poison hemlock, an umbelliferous herb, *Conium maculatum.* By hemlock, Americans mean hemlock spruce, an evergreen tree, *Tsuga canadensis.*

HEMP: common hemp is *Cannabis sativa* (which see); **Bowstring H.,** *Sansevieria;* **Manilla H.,** *Musa textilis;* **Sisal H.,** *Agave rigida* var. *Sisalana.*

HEN-AND-CHICKENS. A proliferous form of the English daisy, *Bellis perennis;* also the thick-leaved rosettes of Cotyledon, used in carpet-bedding, usually as Echeveria.

HENBANE: *Hyoscyamus niger.*

HENFRÈYA: *Asystasia.*

HEPÁTICA (*liver-like,* from the shape of the leaves). *Ranunculàceæ.* HEPATICA. LIVER-LEAF. MAYFLOWER (incorrectly). Stemless low perennials sometimes grown in the wild border for very early spring bloom.

Leaves 3-lobed and sometimes toothed, appearing after the fls. and remaining green over winter: scapes 1-fld., with an involucre of 3 small sessile lvs. simulating a calyx; sepals petal-like, white, pink or purple: achenes short-beaked, pubescent. (Fig. 1808.)—A genus of 3 species, natives of the north temperate zone, grown in open flower-beds for their attractive fls., which appear in early spring; the peculiar foliage is also much admired.

The plants prefer shade, but do fairly well in open places. They should remain undisturbed from year to year, in rich well-drained loam. Well suited to the north or east slope of a rockery. Plants kept in pots in a coldframe until midwinter will quickly bloom at any time desired if removed to a warm room or greenhouse.

Propagation of old plants is easily accomplished by division of the roots. Seeds may be sown very shallow in a moist, shaded soil. The seed is sometimes started in frames in very early spring and the plants transplanted to the garden later, but little is gained by this as the flowers will not show until the next season.

1808. Flower of Hepatica. (Natural size)

tríloba, Choix (*Hepática Hepática,* Karsten. *Anemòne Hepática,* Linn. *A. tríloba,* Hort.). Scapes 4–6 in.: lobes of lvs. obtuse: fls. ½–1 in. across; sepals oval or oblong, obtuse. Earliest spring. E. U. S., Eu., and Asia. B.M. 10. B.R. 387 (as *H. americana*). White-, blue-, and pink-fld. forms have been fixed in cult., and are known as var. **álba,** Hort.; var. **cærùlea fl.-pl.,** Hort.; var. **rùbra fl.-pl.,** Hort. Gn. 26:24. Gn. M. 15:306. G.C. 1873, p. 645 (var. *marmorata,* Moore).

acutíloba, DC. (*H. tríloba* var. *acùta,* Pursh. *Anemòne acutíloba,* Laws, *H. acùta,* Brit.). Fig. 1809. Much like *H. tríloba,* but with the lobes of the lvs. ovate and acute, occasionally the lateral lobes 2-cleft (rarely the middle one): achenes slightly stipitate. E. U. S.

angulòsa, DC. (*Anemòne angulòsa,* Lam.). Plant tufted as in the other hepaticas, hairy: lvs. 3–5-lobed, lobes often serrate: involucre near the fl. toothed; fls. large, blue, whitish or reddish. Hungary. B.M. 5518. G.C. 1865:698. Gn. M. 4:190. Gn. 26, p. 25. G. 2:551. Var. **álba,** Hort. Fls. large, pure white. var. **ròsea,** Hort. A rose-colored form. Var. **lilácina,** Hort. A free-flowering variety with lilac-colored fls.

1809. Hepatica acutiloba. The flowers of hepatica droop and close at night.

K. C. DAVIS.

HEPTAPLEÙRUM: *Schefflera.*

HERACLÈUM (dedicated to Hercules, who used it in medicine, according to Pliny). *Umbellíferæ.* COW-PARSNIP. Perennial or biennial herbs, some of which are used in bold planting effects where there is ample space.

Mostly tall and coarse herbs, with prominent and often very large lobed or pinnate or dissected lvs.: fls. in large umbels, white or purplish, with mostly obcordate petals and the outer ones often larger and cleft and forming rays: fr. obovate, oval or orbicular, dorsally flattened, the oil-tubes extending scarcely below the middle.—Probably 70 species, in the northern hemisphere, one reaching Abyssinia.

Heracleums are not suited for general gardening, but are sometimes grown in wild gardens or parks, or as single specimens on lawns, where a very bold and striking object is desired. The garden species are coarse herbs, growing 5 to 10 feet high, with broad foliage, which is their chief beauty. They are adapted to all soils, but prefer a rich moist soil, and often do well at the edge of running water. They should not be allowed to go to seed. If these plants are grown on an open, sunny lawn, they should be liberally supplied with moisture at all times. Propagated by division or seed.

A. *Plant biennial* (*or biennial-perennial*).

sibíricum, Linn. Lvs. scabrous to hirsute, pinnate or deeply pinnatifid; lfts. oblong or ovate; segms. lobed or palmately parted, serrate: fls. yellowish, without rays; petals about equal: fr. subrotund-oval, deeply notched at the apex. Eu., N. Asia.—Height 5–6 ft., blooming in summer, forming a handsome plant with the much-cut foliage.

platytæ̀nium, Boiss. (*H. éminens*, Lange). Lvs. often 2 ft. across, tomentose beneath, the lower ones trisect and the upper ones less deeply cut, segms. stalked and obtusely palmate-lobed: fls. white, in hairy umbels sometimes 1 ft. across: fr. large, hairy. W. Asia.—Said to be specially valuable for woods and wild-gardens: 4–5 ft. Sometimes perennial.

pérsicum, Desf. Lvs. large, once- or twice-pinnate, glabrous above and pubescent beneath, the segms. in 3 or 4 pairs, much cut into narrow divisions: fls. white, in large somewhat pubescent umbels. W. Asia.—Reaches 12 ft. in height. Sometimes perennial.

pubéscens, Bieb. (*H. caucásicum*, Stev.). Lvs. pinnatisect, pubescent beneath and glabrous above, the segms. 2 or 3 pairs, with elliptic lobes: fls. white, the setulose umbels many-rayed: fr. elliptic, pilose, only the margin aculeate. Asia Minor. Sometimes perennial. Var. **Wílhelmsii,** Boiss. (*H. Wilhelmsii*, Fisch. & Mey.) differs in its prominently aculeate fr.

Lehmanniànum, Bunge. St. stout: lvs. glabrous above and pubescent beneath, the lower ones pinnatisect; segms. 2–3 pairs and pinnatifid and at apex 3-parted, the lobes short-ovate and acute and coarsely toothed: fls. many, dull pink, in large umbels. Turkestan; 3–7 ft. Gn. 66, p. 259.

AA. *Plant perennial.*

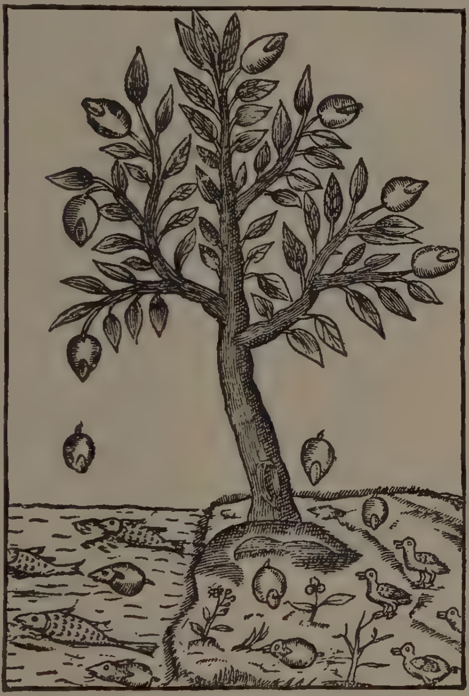
lanàtum, Michx. Lvs. trisect, tomentose beneath; segms. petiolulate, rotund, cordate, lobed and sharply serrate; lfts. of the involucel lanceolate: fr. oval-orbicular. N. Amer., W. Asia. Mn. 4, p. 164.—A striking coarse pubescent plant of low or moist grounds, 4–8 ft. high.

villòsum, Fisch. (*H. gigantèum*, Hort.). Lvs. sinuate-pinnatifid, sharply serrate, acuminate, woolly-tomentose beneath; lfts. of involucres short, bristly, deflexed: fls. white or whitish, in umbels sparingly rayed: fr. elliptic, ciliate, woolly on the back. Caucasus. G.C. III. 3:437; 20:271. J.H. III. 49:115. G. 7:537. G.W. 7, p. 357. Gn.W. 20:47. Gn.M. 14:171.—A bold species, reaching 8–12 ft. in height. Said to be sometimes biennial.

Mantegazziànum, Sommier & Levier. A recent intro. into cultivation and said to be the finest of the genus: lvs. 3 ft. long, deeply cut into many oblong-lanceolate notched lobes, making a gigantic clump: fls. clear white, large, in umbels 4 ft. across, produced in great number. Gn. 59, p. 148; 74, p. 526. G.W. 12, p. 410; 15, p. 636.—This noble species comes from the Caucasus. Seeds were sown at Geneva, Switzerland, in 1893, germinated in 1894, and the plants were 8 ft. high, in 1896. It grows 9 ft. high, and perhaps more. Said to be of easy cult., preferring deep rich soil that is cool and damp; the roots, and especially the tap-root, should remain uninjured, and it is said that it thrives better if not transplanted, although the seedlings may be handled in pots. L. H. B.†

HERBA IMPIA of the old herbalists is *Gifola germanica*.

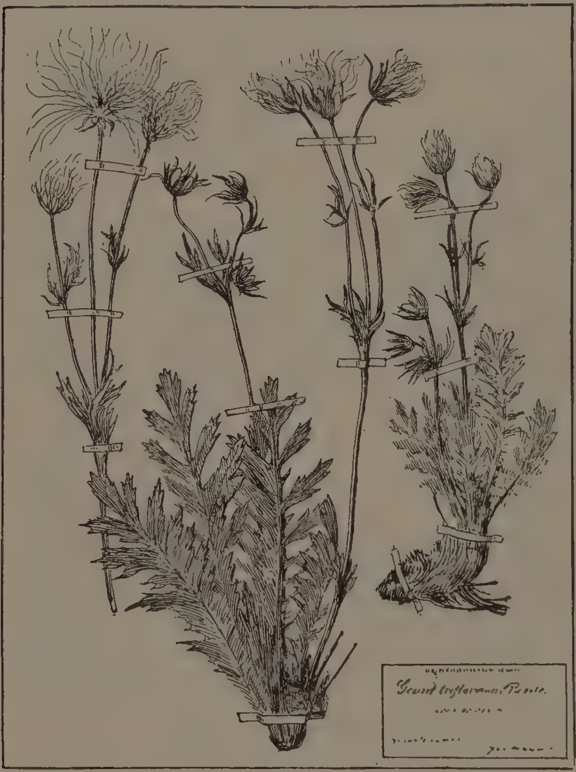
HERBALS. Books on plants, published from the fourteenth to the middle of the eighteenth century, were largely written from the medicinal point of view, and were often called herbals. The scientific point of view of plant-knowledge is conveniently dated from 1753, when Linnæus published his "Species Plantarum." Of the herbalists, John Gerarde is probably read most at the present time. His style is chatty, quaint and personal. One of the notions accepted by the early herbalists was that of the vegetable lamb, which is pictured in this work under *Cibotium* (Fig. 961). Another idea that fascinated these worthy plant-lovers was that of the barnacle goose tree. Fig. 1810 is reproduced from a book by Duret, 1605, and shows how the fruits that fall upon dry land become "flying birds," while those that fall into the water become "swimming fishes." Other conceptions of this goose tree are reproduced in the "Gardeners' Magazine," 35:749, (1892). Almost every large library possesses a few herbals, as Matthiolus, Bauhin, L'Obel and Fuchsius. The largest collection of herbals in America is the one given by the late E. Lewis Sturtevant to the Missouri Botanical Garden at St. Louis. See Agnes Arber (Mrs. E. A. Newell Arber), "Herbals: Their Origin and Evolution," a recent British work. The herbals are invaluable in tracing the growth of ideas about plants.



1810. The Goose Tree of the herbalists.

HERBARIUM. An herbarium is a collection of dried plants systematically named, and arranged in cases for ready reference and protection. In the study of systematic botany such collections have existed for many years, and they are an absolute necessity to the student, supplementing field work. Indeed, without an herbarium, scientific systematic work would be practically impossible, for the identification of species, the study of the plants of any given area and the comparison of the flora of different regions can be conducted thoroughly only where specimens of the plants under consideration are at hand and can be readily consulted. Type specimens of new species are deposited in herbaria, and reference is constantly being made to these types to settle the identity of species when meager descriptions only are available. Floras of distant regions have been written by those who have never visited the places, but have worked on the collections that have been brought back. It is only through such collections of dried plants that publications of the plants of a region are possible. It is a vital supplement to actual work in the field. Large and important herbaria exist at many centers of botanical activity in this country and abroad, while private collections are countless.

There are few collections of pressed specimens of plants embracing the wide range of horticulture, and there should be more of them. The advantage of such herbaria in identifying plants under cultivation and in comparing the many forms that are constantly being evolved, and that do not occupy a place in collections of native plants, must be obvious to everybody. Every horticulturist should have a good herbarium, for it increases very largely the value of his work besides giving much pleasure in the preparation and use of it.



Geum triflorum, Pursh.

1811. A common method of mounting herbarium specimens.

It is like a reference library and it enables a nurseryman to keep his stock true to name. One of the most difficult problems for a systematic botanist or a horticulturist to meet is that of nomenclature, and much trouble and waste time can be avoided by having at hand an authentically named collection, embracing as many forms as possible. A good working herbarium can be made by pressing the cultivated plants at hand and by securing from others specimens of additional forms.

In collecting plants for the press it must be remembered that they are to be mounted on paper 11½ by 16⅜ inches in size. These are standard dimensions. Take up small plants by the roots, and of larger plants secure a branch that will show typical leaves and flower or fruit according to what is desired. Note with each plant, on a label or on a tag slipped on the end of the stem, the important characters that are to be entered on the final label, such as trade name, color of flowers, whether it is annual, biennial or perennial, date, locality, collector, and so on. These should be kept carefully with the plant.

The specimens are then laid for pressing between sheets of unsized paper that will readily absorb the moisture. Newspaper will do, but prepared sheets can be bought at very small cost of any botanical dealer, from whom also can be obtained collecting-boxes, trowels, presses and all other details used in making an herbarium. Plants can be folded once or even twice to be adapted to the size of the sheet, unless too many leaves overlap, in which case two specimens, or even more, can be made of the same plant and pressed separately. A little skill will enable one to lay out his plants artistically, showing upper and under surfaces of the leaves, and the various sides of the flowers. Sometimes it is best to section a thick stem or root. The folder with its inclosed plant or plants and accompanying data is then put between driers, which are sheets of a heavy felt paper, very absorbent. On this is placed another folder, and so on until a pile a foot or more high is reached. This pile is then placed in a press. The best kind of press is a simple, portable one, composed of two frames, each made of strips of hard wood arranged at right angles to each other. The press is then tightened by strong straps. The driers should be changed daily for a few times, and the specimens examined, and then less frequently till they are perfectly dry. Most excellent results in quick drying can be secured by means of sheets of corrugated card board with one side flat. (See J. F. Collins, Rhodora xii. 221, 1910). By placing a sheet between the various driers each plant is isolated from its neighbors, and the circulation of air through the pores speedily dries the plants. Put the press in the sun when possible. The old-fashioned method of using plain boards and a heavy weight on top is not to be recommended.

The specimens should then be mounted on sheets of stiff, white, calendered paper, 11½ by 16⅜ inches, eighteen pounds to the ream being standard weight. This is for a perfectly appointed herbarium. The plants can be kept in the original folders and filed in that way, but, for safety and ease in handling, the specimens should be properly secured to the sheets. The regular method is by gluing them down, fish glue being used, and supplementing this with strips of gummed paper, surgeon's isinglass plaster being the best material. These strips are put over portions of the plant that are liable to separate from the sheet. In some large herbaria gummed strips are used entirely. Each mounted sheet must contain but one species, variety or form, but two or more different collections may be on a single sheet. A label accompanies each collection composed of one or more specimens. A convenient size is 3½ by 1¾ inches. On it should be written the name, locality, date, collector and any useful data such as have been mentioned above.

The mounted sheets are put loose into genus covers of stiff manila paper, 16½ by 11⅞ inches, each cover devoted to a single genus. The name of the genus is written in the lower left-hand corner, and that of the species in the lower right-hand corner. More than one species of the same genus can be put into the same cover. These covers are placed systematically in the herbarium case fitted with pigeon-holes wide and deep enough to hold the covers easily and 6 inches between shelves. The doors must close tightly to keep out insects and dust. The cases are of varying heights, according to convenience, and are generally of wood. The most approved have two rows of about thirteen pigeon-holes each, and are made of steel, thus securing absolute safety.

An herbarium was called "Hortus siccus," or dry garden, by the ancients, but, although in one sense true, it does not convey the correct idea. To the true scientific lover of plants, whether botanist, horticulturist, florist, or nurseryman, a carefully equipped collection of dried plants is not only a great and necessary aid, but a true delight. In them he sees the living plants that they represent, and to dissect a flower, however old it may be, he has but to boil it for a few seconds in a retort, and it can be as easily dissected as if fresh.

Walter Deane.

HERB, HERBS. An herb is a plant that dies to the ground each year, or at least that does not become woody. It may be annual, as bean, pigweed; biennial, as mullein, parsnip; perennial, as dictamnus, rhubarb; many of the perennials live only three or four years effectively. To the gardener, however, the word "herb" is ordinarily synonymous with herbaceous perennial; and he usually has in mind those particular perennial herbs grown for ornament, and which remain where they are planted. Goldenrod, bleeding-heart, sweet william, hollyhock, daffodil are examples. To many persons, however, the word herb is synonymous with sweet herb, and it suggests sage and tansy.

Herbs are grown in an herbary, which, as here understood, is a garden or collection of herbs, and particularly of perennial herbs, since the collection may then be more readily and certainly continued.

Herbs have two kinds of values,—their intrinsic merits as individual plants, and their value in the composition or the mass. It is usually possible to secure both these values at one and the same time. In fact, the individual beauty of herbs is enhanced rather than diminished by exercising proper care in placing them. Planted with other things, they have a background, and the beauties are brought out the stronger by contrast and comparison. It is quite as important, therefore, to consider the place for planting as to choose the particular kinds of plants. The appreciation of artistic effects in plants is a mark of highly developed sensibilities. Happily, this appreciation is rapidly growing; and this fact contributes to the increasing popularity of landscape gardening and ornamental gardening. Some of the best effects in herb-planting are to be seen in the wild, particularly along fences, roads and streams. The planter must remember that herbs are likely to grow larger and more bushy in cultivation than in the wild.

A strip or border along the side of a lawn, or bounding an area, is the best place for a collection of herbs—whether annual or perennial—that are grown for ornamental effect. (See Fig. 597, Vol. I.) About any place there will be special uses of herbs. (See the plans, Figs. 1812, 1813.) The home-maker should cover the bare and unseemly places about the borders of his place (Fig. 1814). He may utilize a rock or a wall as a background (Fig. 1815). He may hide the ground-line about a post (Fig. 1816) or along a fence. Some of the commonest herbs, that excite the least admiration, are handsome when well grown and well placed. (See Fig. 1817.) One should always plant where the herbs will have relation to something else,—to the general design or handling of the place. This will usually be about the boundaries. The hardy border is the unit in most planting of herbs. (See Figs. 1814, 1818.) A rockwork herb border (Fig. 1819) is often useful in the rear or at one side of the premises. It is well to fill some of the corners by the house (Fig. 1820). In remote parts of the grounds, half-wild effects may be allowed, as in Fig. 1821. A pond or pool, even if stagnant, often may be utilized to advantage (Fig. 1822). A good herb out of place may be worse than a poor herb in place. But when herbs are grown for their individual effects, give plenty of room and good care (Figs. 1823, 1824). Other discussions of herbs in relation to planting will be found under *Annuals, Biennials, Border, Landscape Gardening;* also, for special uses, *Alpine Plants, Autumn-Gardening, Kitchen-Garden and Flower-Garden, Spring-Gardening, Wild-Gardening,* and others.

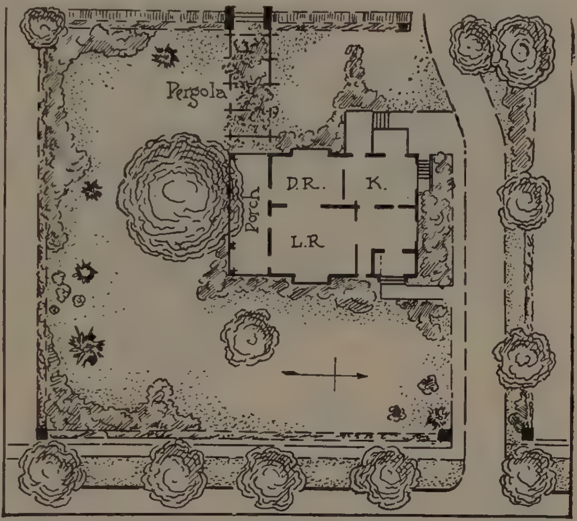
1812. Plan of a residence area on uneven ground. The heavy planting against banks and borders provides areas for herbs as well as for shrubs. The location is indicated of library, dining-room and kitchen.

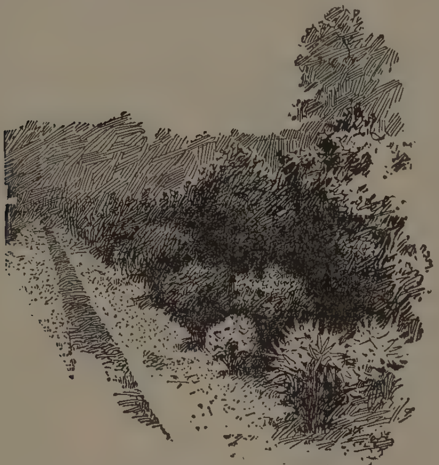


1813. Planting areas in a home ground. The general center is kept open. There are trees along the streets and two on the lawn. About the residence and on the boundaries, as well as in the parking at one side, there is opportunity for herbs and shrubs. D.R., dining-room; L.R., living-room; K., kitchen.

Herbaceous perennials in landscape planting.

No clear definition can be drawn between herbaceous perennials, biennials and annuals, between herbs and woody plants, for there are tender herbs that in a warmer climate would become shrubs or even trees, biennials that become perennials from stolons or offsets, and annuals that become biennials from seed germinating late in the season. Strictly speaking, however, herbaceous perennials are plants having perennial roots with tops that die to the ground annually, such as the columbines, larkspurs, day lilies, peonies, and most sedges, grasses and ferns. It is customary, however, in publications relating to this class of plants as well as in actual use, to include closely allied species with evergreen foliage, such as statice, yucca, sempervivums and certain pentstemons, together with plants having more or less woody and persistent above-ground stems, such as the suffruticose artemisias and the evergreen creeping species of phlox, veronica, vinca, the iberis, the helianthemums, and many alpine plants, while most bulbous-rooted plants which are true herbaceous perennials are separately classified and grown as bulbs.

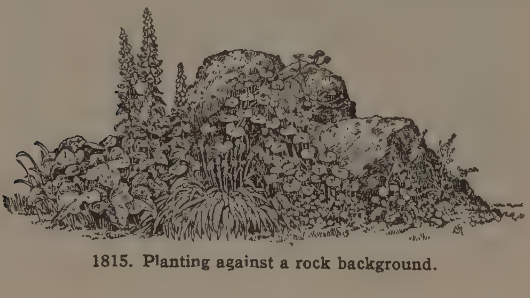
Herbaceous perennials are an exceedingly important element of landscape, for they predominate in the mat of grassy or sedgy plants, covering dry or wet open fields, and in the surface vegetation under woods and shrubby thickets, either as a grass crop, composed of a comparatively few species cultivated for economic purposes, or as a wild growth made up of many species. The most attractive of these native plants are being cultivated and improved more and more from year to year for ornamental purposes, and are planted in the flower-garden, in artificial plantations of shrubbery and in the wild-garden. It is to such natives and to exotics of the same class, which are cultivated for a similar purpose, that reference is to be made hereafter.



1814. An informal herb border.

Fifty years ago nearly every well-to-do family maintained a flower-garden, in which there were from fifty to one hundred and fifty species and varieties of herbaceous perennials, and there were few of the humbler families that did not have a dozen or more species established about their homes. Such plants were distributed by exchange among neighbors and were propagated and offered at retail by dealers, who, however, gradually allowed their stock of plants to run low or abandoned them altogether, until many kinds dropped out of cultivation or were neglected in favor of the tender "bedding out" plants that were brought suddenly into favor by the displays at the Philadelphia Centennial Exposition. Then they gradually declined in favor until the interest was newly revived at the period of the Chicago Exposition.

Since that time there has been such a constantly increasing interest in herbaceous perennials that there are now offered in catalogues of American nurserymen and collectors of native plants, nearly 3,000 species and varieties, exclusive of the many garden forms that are distinguished chiefly by the color of their flowers.



1815. Planting against a rock background.

In use, the species and varieties of herbaceous perennials may be broadly separated into three groups.

First, plants for the garden requiring the favorable conditions of a highly cultivated ground, and careful attention to attain perfection and to persist and increase from year to year. This would include many exotics, some native species and most of the horticultural varieties. Many of such species which would find a congenial place only in the garden have attractive flowers which are so fugitive that they can be enjoyed only on the plant. Other species which are suitable to cut flowers from can hardly be grown in the flower-garden in sufficient quantity liberally to meet the floral requirements of the home, and they should be grown in quantity in the kitchen-garden or in a special cut-flower garden, for their crops of flowers. Included among plants of difficult cultivation with fugitive flowers are the rock or alpine plants, many of which are offered in European catalogues. (See article on *Rock Gardens.*)

Second, plants for the shrubbery, having aggressive habits, which make them rather objectionable in the flower-garden, but fit them to withstand successfully the crowding of shrubs. This class of plants will give variety and prolong the flowering season of shrub borders about lawns, and would be made up chiefly of strong-growing natives and a few of the more persistent exotics.

Third, plants for the wild garden, including the species that require for success some one of the many special conditions prevailing in uncultivated or uncultivable land, or which are so rampant as to require the restraint that some one of these natural conditions will provide. This class of plants would be made up chiefly of natives and a few of the more persistent exotics, and they would be used to enrich groups of native plants under woods, in meadows, along streams, ponds and hedge-rows and on poor soil. There are attractive plants that will and do grow successfully under all these conditions without special cultivation, and many of them may be already on the ground. If every plant in a group of natives is watched for at least a year, it will be found that many are so attractive at one season or another that they will be retained and developed in beauty by the gradual removal of the less desirable kinds, for which others that are more desirable may be substituted.

1816. The ground line is hidden by herbs or shrubs.

In arranging plants in new plantations, or in modifying existing plantations in gardens, lawns or woods, much more effective landscape compositions and more agreeable color effects can be secured by using large quantities of a few sorts than by using a few individuals of many kinds. Groups of different species should be chosen that will give from period to period during the flowering season effective and dominating masses of foliage and color, and all other plants of the garden which appear at the same time should be made subordinate to these.

Herbaceous perennials are propagated by divisions and from offsets, cuttings and seed. Some kinds, as dictamnus and papaver, may be propagated by root cuttings. The exotic species of gardens and many of the more readily grown natives can be obtained in wholesale quantities from nurserymen. A few exotics and a very large number of attractive native species can be procured in wholesale quantities from collectors of native plants, many of whom also offer nursery-grown plants of the best natives and of a few exotics. The attractive native plants in any region can be transplanted with little difficulty if they are collected with a good sod of earth about the roots.

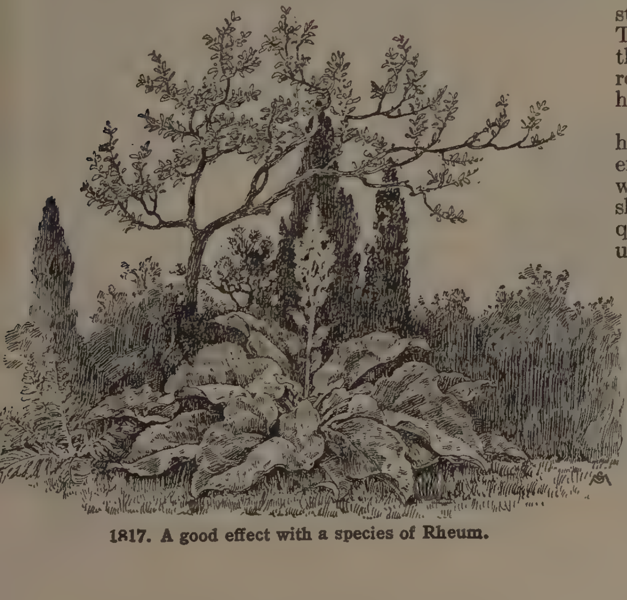
Warren H. Manning.

The culture of herbaceous perennials.

A good number of the herbaceous perennials grown in gardens are exceedingly easy of cultivation, thriving well in any moderately rich soil of suitable physical condition, and enduring winter cold and changeableness and summer heat and drought. There are, however, other species that do not grow well in the American climate, except in more moderate seasons or when placed where the climate is locally modified. Whether the plants one desires to grow be easy or difficult of culture, one should aim first of all for a luxuriant growth, for any time or labor saved by poorly preparing the soil, or any money saved by the use of weak or stunted plants will be regretted later. Unless it is intended to imitate the effect of certain barrens in nature, a garden without luxuriance is lacking in essential quality.

The preparation of ground for planting consists, in the order of importance: in making the soil by openness and fineness suitable for root-penetration to a depth of 18 inches to 2 feet; in providing underground drainage at a depth of at least 2½ feet; in making the soil sufficently fertile; and in making the surface soil not liable to "baking."

Depth and physical condition of soil are very important, and should be one's first care. If the season is short and work must be rushed, it is better to omit the manuring and to devote all one's energy to securing a deep feeding-area for the roots and a fine physical condition of the soil. In the hardy border the roots are able to penetrate far more deeply into the soil than they do usually in a wild state or in ordinary field culture. This vigor of root-growth reaching to good depth, as compared with that of equal vigor but nearer the surface, gives not only greater endurance of drought but aids the plant to endure changeableness of weather, and particularly contributes to hardiness. Many plants are hardy only if protected until the roots are thoroughly established. This is more often noticed with trees and strong-rooted plants that are able to penetrate deeply into the subsoil, but the same applies to herbaceous plants, except that it is usually necessary to loosen the subsoil to ensure penetration by their finer roots to a satisfactory extent. It is not necessary to make the subsoil equal in richness to the upper part, but it should preferably be mixed with a portion of the surface soil.



1817. A good effect with a species of Rheum.

1818. A mixed herbaceous border.

The fine roots are the feeding roots and the surfaces of the soil-particles are their feeding-ground, so that in making the soil-particles smaller the feeding-surface is vastly increased, thus allowing for more roots and closer planting. A fine physical condition can usually be obtained by turning the soil over a few times. No soil should be turned or handled when too moist to crumble, as the clay in the soil is quick to become puddled, and therefore impervious to feeding-roots.

Underground drainage is necessary, since most plants cannot grow in soil filled with stagnant water. When the natural subsoil drainage is not sufficient, artificial means should be used. Unless the drainage is good, many plants will be injured in the rainier seasons or killed in winter. Plants that are not firmly established are often easily killed by excess of moisture about the roots during their dormant season; for example, many bog-plants otherwise perfectly hardy will winterkill if planted late in the fall. A further fact showing the effect of water on dormant roots is that many plants if cut down low enough in the fall to allow water, as from melting snow, to reach the root through the hollow stems, will often be entirely rotted by spring. Thus, when it is necessary to destroy goldenrod, the dry stems may be mown in late autumn with a sharp scythe. The vulnerability of the root to water coming through the stem may be easily seen by comparing in the spring roots of corn, the stalks of which were cut at different heights the previous fall.

In the hardy border, no large amount of coarse or highly fermentable material should be used. The enrichment of the land should, if possible, be made while preparing the border, and any fertilizers used should be well mixed with the soil. Even if a liberal quantity of stable manure is available, it is well to use some potash or phosphoric acid in connection with it. A light top-dressing of manure given in the fall will keep up the fertility, correct the soil in various ways, and afford a slight winter protection, which is appreciated by even the hardiest plants. Over-richness as well as poverty of soil tend to make plants in general less hardy, but usually a great abundance of plant-food should be given, especially for the hardier species with vigorous constitutions and long season of growth. Many plants having a season of rest in late summer do best in land not overly rich, especially if the position is moist.

A loose and open surface soil prevents baking after rains and waterings; saves some of the labor necessary to keep the soil open and friable; allows the growth of many smaller, finer-rooted or creeping plants that cannot grow well in a stiff soil; permits the sowing of many annuals in the border. Many low-growing plants are injured on clayey soil by having the under surfaces of the leaves coated with earth by spattering of rain. A clay soil may be made more loose by the addition of manures, sawdust, coal-ashes, sand or almost any such material. A light, fine mulch should be kept on the surface of a clay soil.

The points to be borne in mind in planting should be healthy plants, careful planting and sufficient thickness of planting. Plants should be obtained which have not been stunted, as a weakened plant will seldom make as good a specimen as if rightly treated from the start. When plants are received from the nursery they may be heeled-in if necessary, but every day plants are left where they have no root-hold on the soil is an injury to them, in proportion to the suitableness of the weather for root-growth. If plants must remain any considerable length of time before being placed in their permanent position it is best to plant them in reserve ground, and to remove them when desired with balls of earth.

Symmetry of top-growth is to some extent, at least, dependent on symmetry of root-growth, so that by careful planting the roots not only become more quickly and strongly active, but give us hope for a more symmetrical plant than can be secured by careless planting. The proper way to place a plant in the ground is to distribute the roots equally about the plant, leaving the tips pointed downward, and then to firm the soil sufficiently about the roots.

A perennial border should be planted rather thick, so that when in foliage it shall appear as one mass. Any showing of soil between plants is not only unnatural but destroys the beauty of the border as a whole. Of course, if plants are wanted for their individual or separate merits, they should be given full room.

Winter protection of herbaceous perennials.

The protection of species not reliably hardy may be accomplished with any material suitable for keeping out frost which is not naturally too moist or close. The material should preferably be heaped over the crown of the plant to shed part of the rain as well as to prevent quick changes of temperature, or wholly to exclude frost, as the plant may need.

The material to be used will be determined for the plants to be protected, by what is on hand or easily obtainable, and by the presence or not of mice or other vermin, which often work under such material as straw. Protected plants should be examined frequently in the winter, and if mice are present they may be killed or driven away by placing a few drops of carbon bisulfide in each hole found. (This is also a good way to rid coldframes of these pests. Plenty of ventilation should be given at the time, as the gas evaporated is destructive to vegetation. As the gas is heavier than air it sinks for the most part down the holes.) If, however, mice are not troublesome, there is no better material for keeping out cold and shedding water than straw. Nature's plant-protection is to use the foliage and stems of the plant themselves, the whole ground surface being covered as the weather grows colder with successive coatings of snow, which protection again grows lighter as spring approaches. This is still the ideal winter protection for plants, but snows are likely to disappear in midwinter and mice are well adapted to live under heavy litter. Where mice are troublesome, a light material may be made by composting leaves, manure rakings from lawns, greenhouse waste, weeds not in fruit as pulled during the season, and the like. The material should be earthy enough to keep mice out, and loose enough to permit of easy removal in spring. It should also be loose enough not to hold too much water in winter. Sawdust and charcoal are examples of such material.

1820. A rear corner, embellished with weeds.

Most of the plants that are largely cultivated need no protection, but all herbaceous perennials, unless they are evergreen or easily smothered, are benefited by a slight covering to protect the soil from alternate freezing and thawing. If the plants are evergreen, a covering to supply shade is often desirable. Other plants, such as *Helianthus decapetalus fl. pl.*, really need protection, not to exclude frost but to lessen considerably the severity of the winter. Still others, as many of the lilies, are best covered to the exclusion of frost. In general, the plants that need complete protection have crowns below the surface, and so may be covered with any amount or kind of material. When it is desired thoroughly to protect crowns on the soil surface, flats may be first placed over the crowns before adding the protection. In most cases, late fall plantings should be protected to some extent, since plants are less hardy when poorly established in the soil. See *Winter Protection*, Vol. VI.

Propagation of herbaceous perennials.

The methods of propagation most used are by seed, by division of the plant, and by cuttings.

Propagation by seed is commonly not of use for the perpetuation of horticultural varieties, although to a varied extent with different species any variety tends to reproduce its characteristics more perfectly the longer it becomes established as a variety. However, some of the garden plants have been separated into their present number of varieties or forms mainly by continual propagation by seed- and plant-selection, and such may be satisfactorily increased by seed. An example might be taken in the hollyhock, although, if a group be left to resow itself, or no seed-selection be maintained, it will soon become mainly composed of single-flowered plants

1819. An herb-covered rockwork.

1821. A tame-wild corner, asparagus and boneset.

by reason of their greater seed-production. In general, propagation by seeds is satisfactory for all established species and for such varieties and forms as have been thoroughly established by selection.

Seed-sowing is not, however, always an easy way to increase many of our garden plants, as there are often a few small items necessary to know concerning a species before success can be assured. Seeds of some perennials remain dormant for a long period after sowing, and, in general, they are very much slower in starting than annuals. Some require more heat than others to germinate, while others require a very cool soil. Many plants brought into cultivation from foreign countries or milder parts of our own land do not produce seed that will remain sound over winter in the earth, nor do seedlings of all hardy perennials withstand the colder season: for example, *Papaver orientale,* a hardy plant itself, produces a great quantity of seed which germinates readily as it falls, but the seedlings will not survive the winter in the northern United States unprotected.

A general rule for seed-sowing would read: Sow the seed when ripe, and then maintain such conditions of temperature and moisture as the seed would receive in the native habitat of the plant. Native American plants not from decidedly milder parts, and many foreign species, may be easily increased by sowing of seed when ripe in the open ground. Among such might be included rudbeckia, aquilegia, coreopsis, monarda, asters (perennial), delphiniums, digitalis, *Dianthus barbatus,* and phlox, all of which will bloom the following season.

Plants usually have one or rarely two particular seasons for blooming, and unless of sufficient size and suitable condition when that season approaches, they will wait for its recurrence before showing flowers, so that by sowing seed early in the spring and giving good cultural attention to the plants, we may expect to flower the first year many plants naturally blooming late in the year, or such as are somewhat floriferous at nearly all seasons: for example, *Lobelia cardinalis* and other lobelias, many of the native asters, *Gaillardia aristata* var. *grandiflora, Bellis perennis,* hollyhocks, platycodon, delphiniums, hardy chrysanthemums, salvias, rudbeckia, dahlias. See *Seeds,* Vol. VI.

Propagation by division is simply the separation of a larger clump of roots and crowns into smaller plants. In the case of plants producing buds on the roots, this division may be carried further, and small pieces of the root used to grow other plants.

The separation of plants as practised in the garden is not usually so much for the purpose of increase as to avoid overcrowding of roots and crowns, with loss of vigor to the plant; for example, a plant of iris, having been undisturbed for a number of years, becomes a tangled circular mat of rootstocks, which in the center cannot find room to grow, and so the plant appears as a large mass of rootstocks, throwing up foliage only on the outer ring. The period in which a plant may remain in any one place without needing separation will vary with the vigor of growth of the plant in each position; a group of plantain lily in a favorable situation will need separation every two years, while in a poorer place it might remain four. However, the average length of time for a few typical species may be given thus: *Bellis perennis,* pompon chrysanthemums, and other strong-spreading, shallow-rooted and easily established plants do best with yearly separation; *Phlox maculata* and monarda every two years; helianthus, asters and many of the compositæ and *Phlox decussata* about every three years; *Convallaria majalis* and many spring-flowering bulbs every four years; such plants as peonies may be left for a longer period.

In general, better flowers are secured from a plant with but one crown than when two or more are left, but unless the new growths are crowding out the central parts or are themselves too numerous to make a vigorous growth possible, division is not necessary. In fact, many plants require a better establishment in the soil than can be given by transplanting or than they can

1822. Pool made attractive by planting of herbs.

quickly secure, and such are best undisturbed until quite overcrowded. The question is whether by dividing a plant better flowers and foliage may be obtained than by allowing it to become more thoroughly established.

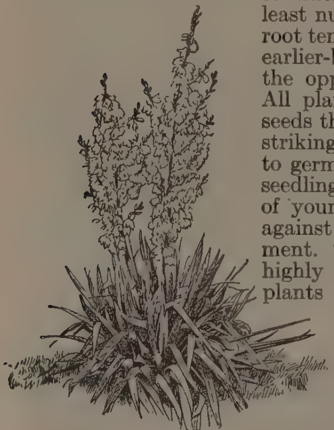
1823. A good subject—Eupatorium.

The time of year for separation will vary as to the blooming season of the plant; that is, for early-blooming plants late summer or early fall, and for late-blooming plants either late fall or spring, preferably the latter, as many otherwise hardy plants are either weakened or killed if disturbed in fall. See *Separation*, Vol. VI.

Propagation by cuttings is rarely useful for the amateur, in the case of herbaceous perennials, but it is an important commercial method. Plants may be obtained from almost any plant having foliage-stems by taking a short piece of the growing wood with a bud, either lateral or terminal, and placing the lower end in moist sand or other material suitable for root-growth. It is usually necessary to have the lower end of the cutting a node or joint of the stem, and to make the temperature of the material in which it is placed higher than that of the atmosphere (which is the relation of the soil and air in sunshine), and to diminish the evaporation from the exposed parts of the cutting by maintenance of a moist atmosphere and by removal in part of the foliage on the cutting. Some experience will be necessary to know the best temperatures for sand and atmosphere and the most desirable degree of ripeness in the wood to be taken, as they will vary somewhat with species. In general, any cutting of growing wood will form roots in moist sand at a temperature suitable for vigorous root-growth of the plant. See *Cuttings*. Vol. II.

The increase of plants by cuttings has the advantages of being rapid and of allowing the perpetuation of any variation noticed on a portion of any plant.

Whichever method of propagation is used, selection of stock for increase should be practised. If by seed, then the best seed from the best plant should be taken. It is considered that seeds borne the least number of nodes from the root tend to produce dwarfer and earlier-blooming plants, while the opposite is equally certain. All plants vary, and often the seeds that will produce the most striking variations are the slower to germinate and are weaker as seedlings, but any mistreatment of young plants is likely to be against any desirable improvement. The double-flowered and highly colored forms of garden plants are generally the results not only of intercrossing of species or selection, or both, but of intense and perfect culture. A poor, starved plant may not retrograde itself, but it is likely to produce seed which will vary.



1824. A good subject—Yucca filamentosa.

Variations in plants are the result of climatic, soil, cultural, and other conditions, and such plant forms are unstable when the conditions which caused them are radically changed. Any new variety naturally reproduces itself best in the region in which it originated, and may easily revert or otherwise change when grown under different conditions. This is especially true in the reproduction by seed of plant variations. See *Breeding*, Vol. I.

In propagating by division, the aim should be not only to secure vigorous plants but to select for increase such plants as appear to be the best. Cuttings also should be taken from selected plants—and the more so since the method is rapid. F. W. BARCLAY.

Herbs for the northeastern states.

Selections for special purposes.—The following lists are to be taken as merely suggestive, and are far from being complete. Nearly all are to be found in the American trade.

1. FOR MOIST AND WET PLACES. Those marked with an asterisk (*) will also thrive under drier conditions.

A. *Near the water's edge.* Actual flooding will not injure any of these.

*Vicia (Orobus) oroboides.
†Yucca filamentosa.
†Yucca flaccida.
†Yucca gloriosa.

3. For Shady Places.

A. The following plants require quite heavy shade; many others succeed almost equally well in sunshine and shade.

Anemone alpina.
Anemone canadensis.
Anemone nemorosa.
Anemone rivularis.
Anemone sylvestris.
Cortusa Matthioli.
Cypripedium.
Hepatica.
Horminum pyrenaicum.
Ourisia coccinea.

AA. Doing better in partial shade; a number of them will stand a moderate amount of sunshine.

Actæa spicata.
Adonis amurensis.
Adonis pyrenaica.
Adonis vernalis.
Anemone apennina.
Anemone ranunculoides.
Arnebia echioides.
Arum italicum.
Arum maculatum.
Asarum europæum.
Asperula odorata.
Astilbe.
Astrantia carniolica.
Claytonia virginica.
Convallaria majalis.
Cypripedium.
Digitalis purpurea.
Dodecatheon.
Doronicum.
Goodyera.
Habenaria.
Helleborus niger.
Helleborus niger var. altifolius.
Liparis.
Myosotis alpestris.
Myosotis palustris.
Omphalodes cappadocica.
Omphalodes verna.
Orchis spectabilis.
Polygonatum multiflorum.
Primula.
Ramondia Nathaliæ.
Ramondia pyrenaica.
Ranunculus aconitifolius.
Sanguinaria canadensis.
Saxifraga Camposii.
Saxifraga muscoides.
Saxifraga Rhei.
Spigelia marilandica.
Spiræa.
Tiarella.
Trillium.
Vancouveria hexandra.
Viola canina.
Viola pedata.

4. Suitable for Carpets or Edgings. The following are of compact habit and mostly low; some are also almost continuous bloomers.

Acæna, species.
Achillea Clavenæ.
Achillea tomentosa.
Achillea umbellata.
Æthionema iberidium.
Ajuga reptans.
Alyssum argenteum.
Alyssum saxatile var. compactum.
Arabis albida.
Arabis aubrietioides.
Arenaria balearica.

4. Suitable for Carpets and Edgings, continued.

Arenaria cæspitosa.
Armeria latifolia var. rosea.
Armeria plantaginea var. leucantha.
Armeria vulgaris.
Armeria vulgaris var. Laucheana.
Artemisia lanata.
Asarum europæum.
Aubrietia deltoidea.
Bellis perennis flore-pleno.
Campanula carpatica.
Cerastium tomentosum.
Daphne Cneorum (treated as an herb).
Dianthus cæsius.
Dianthus chinensis.
Dianthus deltoides.
Dianthus sylvestris.
Erodium Manescavi.
Erysimum pulchellum.
Helianthemum mutabile.
Heuchera sanguinea.
Iberis sempervirens.
Lavandula nana var. compacta.
Linaria hepaticæfolia.
Myosotis.
Nepeta Mussinii
Phlox amœna.
Phlox divaricata.
Phlox frondosa.
Phlox ovata.
Phlox reptans.
Phlox subulata.
Polemonium reptans.
Scabiosa graminifolia.
Silene acaulis.
Silene alpestris.
Silene maritima.
Silene Saxifraga.
Silene Schafta.
Tellima grandiflora.
Thymus citriodorus.
Veronica cæspitosa.
Veronica repens.
Veronica rupestris.
Viola cornuta var. alba.
Viola cornuta var. purpurea.

5. For Cut-flowers. The following varieties are well adapted for cutting.

**=Spring-flowering. †=Summer-flowering. §=Autumn-flowering.*

†Achillea Ptarmica, The Pearl.
†Achillea Ptarmica, Perry White.
†§Aconitum.
†Alstrœmeria.
§Anemone japonica.
*Anemone sylvestris.
†Anthericum.
†Anthurium.
†Aquilegia.
†Armeria vulgaris var. Laucheana.
§Artemisia lactiflora.
*†§Aster.
†§Astilbe.
*Baptisia australis.
†§Belamcanda chinensis (Pardanthus).
†§Boltonia.
†Campanula latifolia var. macrantha.
†Campanula Medium.
†Campanula persicifolia.
†§Campanula pyramidalis.
†Centaurea montana.
†Centaurea ruthenica.
†§Ceratostigma plumbaginoides.
†Chelone Lyonii.
†§Chrysanthemum maximum, in variety.
†§Chrysanthemum, Autumn Glory.
†Cimicifuga racemosa.
†Clematis Davidiana.
†Clematis recta.
†Clematis recta flore-pleno.
†Convallaria majalis.
†Coreopsis grandiflora.
†§Delphinium.
*†Dianthus.
*†Dicentra spectabilis.
†Dictamnus albus.
†Digitalis purpurea.
*Doronicum.
†Epilobium angustifolium.
†§Erigeron.
§Eupatorium.
†Euphorbia corollata.
†§Gaillardia aristata.
†Gaillardia grandiflora.
†§Geum coccineum, Mrs. Bradshaw.
†Gypsophila acutifolia.
†Gypsophila paniculata.
†Helleborus niger.
§Helenium autumnale var. superbum.
§Helenium autumnale var. pumilum.
†Helenium Hoopesii.
†§Helianthus.
†§Heliopsis lævis var. Pitcheriana.
†§Hemerocallis.
†§Hesperis matronalis.
†Heuchera sanguinea.
§Hosta plantaginea var. grandiflora.
†§Hypericum Moserianum.
*Iberis sempervirens.
†Incarvillea Delavayi.
†Iris germanica.
†Iris Kaempferi.
†Iris sibirica.
†§Kniphofia (Tritoma).
Lathyrus latifolius.
†§Liatris pycnostachya.
§Lobelia cardinalis.
†§Lobelia syphilitica.
†Lupinus polyphyllus.
†Lychnis.
†§Lysimachia clethroides.
†§Lythrum Salicaria var. roseum superbum.
*†Myosotis.
†Œnothera speciosa.
†Pæonia.
*†Papaver.
†§Pentstemon.
†Phlox Arendsii.
*Phlox divaricata.
†§Phlox paniculata.
†Phlox suffruticosa.
†§Physostegia virginiana.
†Platycodon grandiflorum.
†§Plumbago Larpentæ.
*†Polemonium.
†Potentilla.
*Primula.
†Pyrethrum hybridum.
§Pyrethrum uliginosum.
†Rehmannia angulata.
†§Rudbeckia.
†Salvia azurea.
†Salvia pratensis.
†Saxifraga pyramidalis.
†§Scabiosa caucasica.
§Sedum spectabile.
†Sidalcea candida.
†Sidalcea malvæflora var. Listeri.
§Solidago.
†Spiræa.
†§Statice latifolia.
†§Stokesia cyanea.
†§Thalictrum adiantifolium.
§Thalictrum dipterocarpum.
†Thermopsis caroliniana.
*†Trollius.
†Valeriana officinalis.
Veronica longifolia var. subsessilis.
Veronica spicata.
†Yucca filamentosa.

In addition to the foregoing list, there are a number of other plants usually accepted and often listed as herbaceous plants, such as montbretias, eremurus, lilium, which are suitable for cutting. These will be found under *Bulbs*.

6. **For Bold Effects.** The following plants are striking in their habit and for this reason are very serviceable in groups or as single specimens. Some are foliage plants with comparatively inconspicuous flowers.

**=Tall varieties, growing 5 feet or more in height.*
†=Medium varieties, growing from 2 to 4 feet.
§=Varieties with striking foliage.

*Acanthus mollis var. latifolius.
†Anemone japonica.
†Artemisia lactiflora.
†§Aruncus sylvester.
*Arundo Donax.
*Astilbe Arendsii.
*Astilbe Davidii.
*Astilbe grandis.
§Bambusa.
†Baptisia australis.
†Clematis recta.
*Crambe cordifolia.
*Delphinium hybridum.
†Dictamnus albus.
†Echinacea purpurea (Rudbeckia).
§Elymus glaucus.
§Eryngium amethystinum.
†Filipendula rubra var. venusta.
§Gunnera chilensis.
*Helenium autumnale var. superbum.
†Helenium, Riverton Beauty.
*Helianthus mollis.
†Helianthus decapetalus, Soleil d'Or.
*Helianthus orgyalis.
†Hemerocallis aurantiaca var. major.
†Hemerocallis flava.
†Hemerocallis Thunbergii.
§Heracleum villosum.
†§Hosta plantaginea var. grandiflora.
†Hypericum Moserianum.
†Kniphofia Uvaria var. nobilis.
†Kniphofia Pfitzeri.
†Pæonia.
†Papaver orientale.
†Phlox paniculata.
*†Polygonum sachalinense.
*§Polygonum Sieboldii.
§Rheum palmatum var. atrosanguineum.
*§Rodgersia æsculifolia.
*§Rodgersia pinnata.
*Rudbeckia, Golden Glow.
*Rudbeckia maxima.
*Thalictrum dipterocarpum.
†Veronica longifolia var. subsessilis.
*§Yucca filamentosa.

7. **For Forcing and Greenhouse Decoration.** The following species are suitable for forcing. As a general rule, they succeed best in a temperature not exceeding 50° at night. Many of these can be potted, but some of the more robust sorts are better grown in boxes or benches. The astilbes and spireas will thrive in a higher temperature than other varieties named.

Alyssum saxatile var. compactum.
Aquilegia cærulea.
Aquilegia chrysantha.
Arabis alpina.
Aster alpinus.
Aster subcæruleus.
Astilbe Arendsii.
Astilbe Davidii.
Astilbe grandis.
Aubrietia, all varieties.
Campanula carpatica.
Campanula Medium.
Campanula pyramidalis.
Cheiranthus Allionii.
Cheiranthus alpinus.
Coreopsis grandiflora.
Cypripedium acaule.
Cypripedium pubescens.
Cypripedium spectabile.
Delphinium grandiflorum.
Delphinium hybridum.
Dianthus cæsius.
Dianthus deltoides.
Dianthus, Napoleon III.
Dianthus neglectus.
Dicentra spectabilis.
Digitalis purpurea.
Digitalis purpurea var. gloxiniæflora.
Dodecatheon Meadia.
Francoa ramosus.
Gerbera Jamesonii.
Geum coccineum, Mrs. Bradshaw.
Helleborus niger var. major.
Hepatica angulosa.
Hepatica triloba.
Hesperis matronalis.
Heuchera sanguinea.
Hosta lancifolia var. albomarginata.
Iberis sempervirens.
Incarvillea Delavayi.
Iris cristata.
Iris pumila.
Myosotis, all kinds.
Pæonia, all varieties.
Papaver nudicaule.
Phlox amœna.
Phlox Arendsii.
Phlox divaricata.
Phlox subulata.
Phlox suffruticosa, Miss Lingard.
Polygonatum multiflorum.
Primula, all species.
Pyrethrum hybridum.
Saxifraga, all species.
Sisyrinchium angustifolium.
Spiræa, many species.
Trillium, all species.
Trollius, all species.
Vicia oroboides (Orobus).
Viola, all kinds.

8. **New and Very Desirable Species.** The following list comprises some of the best introductions of recent years, up to and including 1914.

Achillea Ptarmica, Perry White.
Aconitum Fischeri var. Wilsonii.
Aconitum Hemsleyanum.
Anchusa italica, Dropmore.
Anchusa italica, Opal.
Anchusa italica, Perry variety.
Anchusa myosotidiflora.
Anemone vitifolia.
Arabis aubrietioides.
Artemisia lactiflora.
Aster Amellus, Beauty of Rowdorf.
Aster, Beauty of Colwell.
Aster, Feltham Blue.
Aster novæ-angliæ, L. Fardel.
Aster novi-belgii, St. Egwin.
Aster, Peter White.
Astilbe Arendsii, Ceres.
Astilbe Arendsii, Pink Pearl.
Astilbe Arendsii, Queen Alexandra.
Astilbe Arendsii, Salmon Queen.
Astilbe Arendsii, Vesta.
Campanula carpatica, Kilnfield White.
Campanula, Warley.

8. **New and Very Desirable Varieties**, continued.

Chrysanthemum, Autumn Glory.
Chrysanthemum maximum, Etoile de Nouvelles.
Chrysanthemum maximum, King Edward VII.
Chrysanthemum maximum, Mrs. Tersteeg.
Chrysanthemum, Rosy Gem.
Clematis recta flore-pleno.
Delphinium Belladonna semi-plena.
Delphinium, J. S. Brunton.
Delphinium, Rev. E. Larcelles.
Delphinium Moerheimei.
Delphinium, Persimmon.
Geum coccineum, Mrs. Bradshaw.
Gypsophila paniculata flore-pleno.
Helenium autumnale, Riverton Beauty.
Helenium autumnale, Riverton Gem.
Heuchera gracillima, Perry var.
Heuchera, Nancy Perry.
Heuchera, Scarlet Spray.
Heuchera, Shirley.
Kniphofia, John Benary.
Kniphofia, Twilight.
Kniphofia, Unique.
Iris germanica, Kashmir White.
Iris germanica, King of Iris.
Iris germanica, Lady Foster.
Iris germanica, Lohengrin.
Iris germanica, Miss Willmott.
Iris interregna, varieties.
Lupinus polyphyllus var. Mœrheimei.
Phlox Arendsii, all varieties.
Phlox paniculata, Frau A. Buchner.
Phlox paniculata, Eliz. Campbell.
Phlox paniculata, Rheinlander.
Phlox paniculata, Rynstrom.
Phlox paniculata, G. A. Strohlein.
Primula Beesiana.
Primula Bulleyana.
Primula Forrestii.
Primula pulverulenta.
Primula sikkimensis.
Primula Veitchii.
Salvia virgata var. nemorosa.
Sedum spectabile, Brilliant.
Senecio clivorum.
Senecio tanguticus.
Thalictrum dipterocarpum.
Viola cornuta var. purpurea.

W. N. Craig.

Herbs in Canada.

Many species and varieties of herbs succeed admirably in Canada, the covering of snow which they have in winter, in most places, affording them excellent protection from extreme cold and sudden changes of temperature. The conditions are thus, in many places, more favorable than farther south, where they are exposed, for long periods, to cold and changeable weather.

Following are lists of best herbaceous perennials.

One hundred best hardy herbaceous perennials for the Dominion of Canada, except prairie provinces.

**=Best twenty-four.*

Achillea Ptarmica fl.-pl., The Pearl.
Aconitum Fischeri.
Aconitum Napellus var. bicolor.
Adonis vernalis.
Æthionema grandiflorum.
Althæa rosea (Hollyhock).
*Anemone japonica varieties.
Anemone patens var. Nuttalliana.
Anemone sylvestris.
Aquilegia chrysantha.
*Aquilegia cærulea and hybrids.
Aquilegia flabellata var. nana alba.
Aquilegia glandulosa.
Aquilegia oxysepala.
*Arabis albida var. flore-pleno.
Aruncus sylvester var. Kneiffi.
Aster alpinus var. superbus.
Aster Amellus var. amelloides.
Aster Amellus var. bessarabicus
Aster novæ-angliæ, Mrs. J. F. Rayner.
Campanula carpatica and varieties.
Campanula lactiflora.
Campanula latifolia var. macrantha.
*Campanula persicifolia and varieties.
Campanula pyramidalis.
*Chrysanthemum maximum, varieties.
Cimicifuga americana.
*Clematis recta.
Convallaria majalis.
*Coreopsis grandiflora.
Delphinium Belladonna (a name for garden forms).
Delphinium cashmerianum.
*Delphinium grandiflorum (D. chinense).
*Delphinium hybridum and varieties.
*Dianthus plumarius, Mrs. Sinkins.
*Dicentra spectabilis.
Dictamnus albus.
Doronicum plantagineum var. excelsum.
Echinacea purpurea.
*Epimedium alpinum var. rubrum.
Erigeron speciosus var. superbus.
Filipendula hexapetala var. flore-pleno.
Filipendula rubra.
Gaillardia aristata.
Gypsophila paniculata.

Papaver orientale.
Phlox paniculata, in great variety.
Platycodon grandiflorum.
Pyrethrum uliginosum.

W. T. Macoun.

Western perennials for western gardens.

A leading principle in the prairie style of landscape gardening is restoration of the native flora. The history of every country shows three stages in the development of taste. First, the native flora tends toward extermination by agriculture, drainage, fires, and the growth of cities. Second, cosmopolitanism spreads everywhere, until the gaudiness of temporary plants, like cannas and coleus and the artificiality of complicated geometric beds tends to make all parts of the world look alike. Third, people recognize that the greatest variety and highest beauty come from restoring and intensifying the "local color" originally impressed upon each distinct region by eons of experiment on the part of nature. This "return to nature," which has taken many centuries in Europe has begun in Illinois within a single century, owing largely to the high percentage (89 per cent) of its arable land. The process of banishing native vegetation went so fast and far that, a few years ago, the secretary of the Illinois Horticultural Society declared, "It is probable that no equal area of the earth's surface has been degraded to such utter ugliness and monotony as Illinois." But, in 1906 to 1909, nearly $4,000,000 was spent on the West Side parks of Chicago under the direction of Jens Jensen, with restoration as the leading idea. The largest and most impressive restorations in the Middle West are, "the Prairie River" in Humboldt Park, and "Chicago during the carboniferous era" in the greenhouses at Garfield Park. In all western restorations, perennials are often more important than trees or shrubs, because the former are the characteristic vegetation of prairies, or treeless areas, and because there are more species of western herbs than of western woody plants.

Perennials that do not cross the Alleghanies.—Of the 179 plants that do not cross the Alleghanies, according to Brendel ("Flora Peoriana," pp. 76–78), thirty-four are perennials cultivated for ornament. Of western origin, he thinks, are the following: *Anemone caroliniana, Chrysopsis villosa, Clematis Simsii* (*C. Pitcheri*), *Echinacea angustifolia, Helianthus lætiflorus* and *H. scaberrimus* (*H. rigidus*), *Lithospermum linearifolium* (*L. angustifolium*), *Lythrum alatum, Petalostemon candidus* and *P. violaceus, Camassia esculenta*, (*Quamasia hyacinthina*), and *Solidago glaberrima* (*S. missouriensis*, Hort. not Nutt.). The above came originally from the Great Plains. Of southern origin are: *Amsonia Tabernæmontana* (*A. Amsonia*), *Baptisia leucantha, Boltonia asteroides, Coreopsis lanceolata, Liatris* (or *Lacinaria*) *cylindracea* and *L. pycnostachya, Lepachys* (or *Ratibida*) *pinnata, Rudbeckia subtomentosa* and *R. triloba* (biennial), *Silphium laciniatum, S. perfoliatum*, and *S. terebinthaceum*. The origin of the eleven following species is not stated: *Cypripedium candidum, Echinacea purpurea, Eupatorium altissimum, Filipendula rubra* (*Ulmaria rubra, Spiræa lobata*), *Helianthus doronicoides, Heuchera hispida, Hibiscus militaris, Jeffersonia diphylla, Phlox glaberrima* and *P. maculata*, and *Solidago ohioensis*.

State flowers.—Before a legislature chooses a state flower, lists like the above should be carefully studied by impartial observers, to make sure that the flowers recommended are really characteristic, easy of cultivation, and lend themselves to the decorative arts. When sentiment alone is allowed to decide these matters, plants are often chosen which it is impracticable to grow. Yet, it is a great advantage to choose a flower that can be grown in every garden. One prairie state chose the "prairie violet." Doubtless the showy *Viola sororia* was meant, yet this is a native of the woods, and it is as common East as West. The bird's-foot violet (*V. pedata*) is showy on the dunes, and, even when conventionalized by the decorative arts, would be distinct, but it is not confined to the West. Its western representative (*V. pedatifida*) is a genuine prairie plant, but infrequent and presumably impracticable for cultivation. Unfortunately, *V. sororia* makes its response to good soil by producing leaves instead of flowers.

City flowers.—The western cities have now definitely begun the practice of choosing city flowers to be grown in every yard and woven into their civic art. Perhaps the most appropriate way to symbolize the history or ideals of each locality is to choose a flower characteristic of its peculiar scenery or soil type. The soil type can be determined by correspondence with the Bureau of Soils, United States Department of Agriculture. The prairie states belong chiefly to the Upper Austral zone, but there are a few cities and counties that can choose their public planting motives from the Lower Austral and some from the Transition zones. "Life Zones and Crop Zones," by C. H. Merriam (Bulletin No. 10, Division of Biological Survey), gives the trees characteristic of each zone, and these may be helpful in suggesting the most characteristic plant-associations of each locality. The nearest local botanist will usually give invaluable help.

The best garden perennials.

The following are all sun-loving plants, succeeding in ordinary garden soil without special care. They are arranged according to the month in which they ordinarily begin to bloom, although, of course, considerable variation in season may be expected.

White.—April: *Sanguinaria canadensis*. May: *Phlox divaricata* var. *alba grandiflora*. June: *Anemone canadensis, Pentstemon Cobæa* var. *albus*. July: *Euphorbia corollata, Phlox paniculata* vars. Miss Lingard, Snow Queen, White Queen, Albion, Diadem, Hermione, Helena Vacaresco, and Von Lassburg, *Physostegia virginiana, Thalictrum polygamum*. August: *Boltonia asteroides, Hibiscus Moscheutos* var. *albus, Salvia azurea* var. *alba, Aster ptarmicoides*. September

Eupatorium urticæfolium. October: *Aster commutatus. A. ericoides* var. Sensation, *A. Tradescantii.*

Blue.—April: *Iris cristata* and *I. verna, Phlox Stellaria.* May: *Amsonia Tabernæmontana, Baptisia australis, Phlox divaricata, Polemonium reptans, Camassia esculenta.* June: *Tradescantia virginiana, Clitoria mariana.* July: *Delphinium carolinianum* (bluish white). August: *Eupatorium cœlestinum.* October: *Aster lævis* and *A. amethystinus.*

Pink.—June: *Tradescantia virginica* var. *delicata.* July: *Phlox paniculata* vars. Grévin, Lady Molly, Sonnenkind, and Le Soleil, *Echinacea purpurea* var. *rosea* (*Rudbeckia elegans rosea*), *Physostegia virginiana* var. *speciosa.* August: *Hisbiscus Moscheutos* and *H. militaris.* September: *Boltonia asteroides, Aster longifolius, A. ericoides* var. Sensation, *A. novæ-angliæ* var. Ryecroft Pink, *A. paniculatus* var. Triumph.

Rose and rosy purple.—July: *Physostegia virginiana.* August: *Liatris* (*Lacinaria*) *pycnostachya, L. scariosa,* and *L. squarrosa.* September and October: *Aster novæ-angliæ* var. *roseus, Lythrum alatum.*

Purple and violet.—May: *Clematis Simsii* (*C. Pitcheri*), *Sedum pulchellum.* July: *Phlox paniculata* var. Ryecroft Purple, *Echinacea purpurea.* August: *Aster Shortii.* September: *Aster patens.*

Crimson.—June: *Callirhoë involucrata.* July: *Phlox paniculata* var. Lord Kelvin. September: *Aster novæ-angliæ* var. *coccineus.*

Magenta.—May: *Phlox pilosa, P. stolonifera* (*P. reptans*). June: *Phlox glaberrima, P. maculata.* July: *Phlox paniculata* vars. Champs Elysées. Eclaireur and Obergärtner Wittig.

Scarlet.—May: *Aquilegia canadensis.* June: *Lilium canadense* var. *rubrum, L. umbellatum,* Pursh. not Hort. July: *Pentstemon barbatus* var. *Torreyi* (from the Great Plains), *Phlox paniculata* var. Stendahl, *Lilium canadense* var. *rubrum.* August: *Gaillardia aristata* var. Glory.

Yellow.—May: *Caltha palustris* var. *flore-pleno, Aquilegia canadensis* var. *flavescens, Ranunculus repens* var. *flore-pleno, Viola Nuttallii.* June: *Œnothera missouriensis, Lepachys pinnata, Baptisia tinctoria, Coreopsis lanceolata* and *C. grandiflora.* July: *Coreopsis verticillata, Helianthus mollis, H. lætiflorus* and *H. strumosus* (*H. macrophyllus*), *Silphium perfoliatum, Chrysopsis villosa, Asclepias tuberosa, Rudbeckia speciosa* and *R. Newmanii, Heliopsis helianthoides, H. lævis* and var. *Pitcheriana, H. scabra* var. *zinniæflora.* August: *Rudbeckia fulgida* and *R. subtomentosa, Coreopsis tripteris, Helenium autumnale* and var. *pumilum magnificum, Helianthus decapetalus* vars. *multiflorus, maximus,* and Soleil d' Or, *Helianthus scaberrimus* (*H. rigidus*) var. Miss Mellish. September: *Helianthus orgyalis.* October: *Helianthus Maximilianii.*

Orange.—May: *Lithospermum canescens.* July: *Asclepias tuberosa.*

Perennials classified by height.—It is easy to get flowers of medium height any month from the color lists given above. The prairie has also produced many tall perennials suitable for gardens, especially in the genera Helenium and Helianthus, which furnish many species that grow taller than a man. Many asters and the boltonias will attain 5 feet under favorable conditions, and so will *Lilium canadense* and *L. superbum,* if they have shade and unfailing moisture. The prairie has produced no edging plants equal to the pinks, alyssums, or rock cresses. Perhaps the best western garden plants growing 12 inches high or less are: April: *Iris cristata* and *I. verna, Sanguinaria canadensis.* May: *Fragaria virginiana* var. *illinoiensis, Lithospermum canescens, Ranunculus repens* var. *flore-pleno.* June: *Sedum pulchellum* and *S. ternatum, Œnothera missouriensis, Callirhoë involucrata,* and the plant known to the trade as *Erigeron glabellus,* which blooms in October, and is presumably different from the spring-blooming *Erigeron asper,* to which *E. glabellus* has been referred (although some retain *E. asper* as a synonym of *E. glabellus*).

Perennials for special uses and soils.

Perennials for cut-flowers.—The ideal subject for cutting lasts a long time, has long stems, is fragrant, and has large or numerous flowers. About the only perennial that comes up to this standard is the garden phlox, but long stems and large flowers are produced by many species of Gaillardia, Helianthus, Heliopsis, and Rudbeckia. Smaller flowers in abundance are produced by Aster, Boltonia, and Coreopsis. Long and effective spikes are produced by Liatris, and Physostegia. For lightening bouquets, *Galium boreale* is an excellent substitute for *Gypsophila paniculata.*

Perennials for fragrance.—The phloxes are fragrant at dusk, but otherwise the prairie seems to have produced no fragrant flowers of the first importance for cultivation.

Perennials for the collector.—The groups that appeal most to collectors are those having the greatest variety in form, color, and size. Perennial phlox (*P. paniculata*) has produced more varieties in cultivation than any other American flower, one Scotch catalogue offering 346 kinds. The color range is from purple through crimson-pink to white, and the chief forms are the large-flowered, large-trussed, and halo. *Gaillardia aristata* has produced 102 varieties, ranging from yellow to red, the chief forms being toothed, laciniate, quilled, and reflexed, with some double varieties (e.g. *G. splendidissima plena*) and a maximum size of 5½ inches (James Kelway). The perennial sunflowers make a very impressive collection, but require much space unless only a few of each kind are grown. They are all yellow-flowered, and offer no great variety of form but they vary in season from July to October, and in height from 3 to 12 feet, with single or double flowers and yellow or brown disks. The best twelve species of sunflower are native to the prairie. The coneflowers (comprising Rudbeckia and Lepachys) make a more elegant and varied collection with a wider range of color, the prominent disks being green, yellow, brown, or purple, while the rays range from yellow to reddish brown and purple. Thirty-nine species and seventy-one varieties of perennial asters or Michælmas daisies are offered by a single English dealer. There are thirty-nine species native to the prairie, and in cultivation. The New Jersey aster (*A. novi-belgii*), which is not native to the prairie, has produced the greatest number of varieties, viz., forty-five. Asters are more satisfactory in borders by themselves than in the garden.

Perennials for light soils.—All the artists of the prairie school have been deeply influenced by the sand-dunes near Chicago, to which the Prairie Club has conducted several hundred excursions. The flowers of the dunes have been introduced into the gardens of Chicago, a large part of which is built on dunes. In perhaps a third of the city, the conventional material of the nurseries fails to give satisfaction, but the plants of the dunes succeed admirably. The greatest color shows at the dunes are produced by *Lupinus perennis* and *Viola pedata,* which bloom by the thousands in sand, but commonly fail in rich soil. Other showy perennials of these and other inland dunes are, *Asclepias tuberosa, Euphorbia corollata, Liatris scariosa, Lathyrus maritimus, Lithospermum canescens,* the fleshy-leaved *Solidago Virgaurea, Tephrosia virginica,* and *Physostegia virginiana,* which assumes fleshy leaves and dwarf habit in sand. One of the best grasses is *Calamovilfa longifolia,* and one of the best gray-leaved plants is *Artemisia canadensis.*

Perennials for the roadside.—The greatest opportunity for the public use of perennials in the prairie states is connected with the roadsides, which can be turned into a public park without the cost of buying the land.

LIII. Good use of spring flowers.—Mertensia virginica.

The roadside is the chief sanctuary of the native flora, and if the movement to preserve and restore the prairie flowers has progressed farther in the prairie states than others it may be because the prairie states must, to a great extent, create their own scenery. The following list contains very characteristic and beautiful flowers that can be bought or collected cheaply, and are easy of cultivation, but not weedy. Many of them are excellent for cut-flowers, but few of them would be likely to encourage vandalism. To this list should be added three important bulbous plants which can be used to edge the shrubbery, viz., dodecatheon, mertensia, and camassia. The following plants are all sun-loving species, and most are well adapted to stand drought: May: *Phlox divaricata.* June: *Callirhoë involucrata, Tradescantia virginica, Phlox glaberrima* and *P. maculata, Eryngium aquaticum.* July: *Phlox paniculata, Echinacea purpurea, Helianthus mollis, H. lætiflorus, H. helianthoides, Asclepias tuberosa, Rudbeckia speciosa, Heliopsis scabra.* August: *Gaillardia aristata, Boltonia asteroides, Liatris pycnostachya, Aster novæ-angliæ, Rudbeckia subtomentosa, Helenium autumnale, Helianthus decapetalus.* September: *Aster ericoides, A. paniculatus,* and *A. patens, Helianthus orgyalis.* October: *Aster amethystinus, A. lævis,* and *A. commutatus, A. Tradescantii, Helianthus Maximilianii.*

Perennials for shade.—A great problem in the prairie states is restoration of wild flowers to woodlots that have been pastured. The chief wooded areas are along streams and whenever they exist elsewhere they furnish the only scenic foil to, or relief from, the prairie. The western woods are scarcely differentiated from the eastern woods in spring unless by greater abundance of American bluebells (*Mertensia virginica*), and wild blue phlox (*P. divaricata*). The snow or early wake-robin (*Trillium nivale*) is often the first flower, preceding the hepaticas. Perhaps the most characteristic spring wild flower of the woods is *Erythronium albidum,* which replaces the yellow adder's-tongue of the East. In summer, the most characteristic species, probably, are *Helianthus decapetalus* and *H. divaricatus. Lilium canadense* and *L. superbum* grow taller and produce more flowers in moist woods than open places. At the edge of the woods, *Anemone virginiana* and *A. canadensis* bloom freely. Phloxes appear to much better advantage in woods where their magenta color is toned down by the shade, especially when they are seen amid grass. The best planting policy ordinarily is to spend money chiefly near the trails, a favorite foliage plant beside trails being the maidenhair fern (*Adiantum pedatum*). Perhaps the best large masses of color are produced by colonies of *Cimicifuga racemosa* and *Aralia racemosa,* the berries of which change from green through purple to scarlet during the summer.

In autumn, many species of aster and goldenrod fill the woods, notably *Aster cordifolius* and *A. divaricatus,* and *Solidago cæsia.*

Perennials for rock-gardens.—Natural rocks are so rare in the West that rock-gardens hardly seem appropriate. Among the best flowers native to western rocks are *Aquilegia canadensis, Campanula rotundifolia, Eupatorium cælestinum, Fragaria virginiana* var. *illinoiensis, Heuchera americana, Oxalis violacea, Sedum pulchellum* and *S. ternatum,* and *Silene virginica.*

Perennials for bog-gardens.—Sphagnum bogs in convenient locations are getting rare in the West, but western people are beginning to buy them because they contain some of the most beautiful flowers, especially orchids, pitcher-plants, and members of the heath family. Many of these plants and the fringed gentian require sphagnum moss or peat. They present a higher type of beauty than the plants that grow in ordinary muck or wet soil, which are named in the next list.

Water-loving perennials.—The following are suitable for the margins of ponds, lakes, brooks, rivers, and water-gardens. They require more water than it is convenient to give them in ordinary flower-gardens, and even if they thrive they are likely to look out of place: April: *Caltha palustris.* May: *Chamælirium luteum, Senecio aureus, Menyanthes trifoliata.* June: *Iris versicolor, Parnassia caroliniania, Angelica atropurpurea.* July: *Angelica hirsuta, Aster puniceus, Caltha palustris, Lilium canadense* and *L. superbum, Thalictrum polygamum* (*T. Cornuti*). August: *Lobelia cardinalis, Aster paniculatus, Eupatorium purpureum, Hibiscus Moscheutos.* September: *Gentiana Andrewsii, Helenium autumnale, Pontederia cordata.* October: *Helianthus orgyalis* and *H. Maximilianii.* Colored water-lilies are not used in the prairie style of landscape gardening as they spoil the purity of the composition, since the white water-lily is the only one native to prairie rivers. Perhaps the finest aquatic plant yet to be naturalized in western water-gardens is the yellow lotus (*Nelumbo lutea*).

Bird-pools.—Few, if any, perennials are worth planting around bird-pools to furnish food, but water-loving perennials are important for finishing such compositions. Where the gardenesque style uses German or Japanese iris, variegated calamus, eulalia, and eastern cattail, the prairie style uses *Iris versicolor,* green calamus, bluejoint (*Calamagrostis canadensis*), and western cattail (*Typha angustifolia*). Several wild flowers of the lily family suggest the flight of birds by their habit, e.g., *Polygonatum giganteum.* In the prairie school, the motive is often to reproduce something like the characteristic local spring. Among the original plants native to springs which Brendel records are, *Archangelica atropurpurea, Aster corymbosus* and *A. umbellatus, Caltha palustris, Parnassia caroliniana, Cypripedium spectabile* and *C. candidum,* the last of which is distinctly western.

Bibliography.—H. C. Cowles, "The Plant Societies of Chicago and Vicinity" (1901); Frederick Brendel, "Flora Peoriana (1887); Brendel in Fred Gerhard, "Illinois as It Is" (1857), pp. 271–8; H. A. Gleason, "A Botanical Survey of the Illinois River Valley Sand Region" in Bot. Gaz. 7:149–194 (1907); and "The Vegetation of the Inland Sand Deposits of Illinois," Bull. Ill. State. Lab. Nat. FRANZ A. AUST.

Perennial herbs for the South.

1. *Piedmont Zone* extends from the Mountain Zone to the "Fall Line," which follows approximately the following cities: Weldon and Raleigh, North Carolina; Camden and Columbia, South Carolina; Augusta, Milledgeville, Macon and Columbus, Georgia; Montgomery, Alabama; Columbus and Holly Springs, Mississippi.

Sun-loving plants for Piedmont Zone.

Acanthus mollis.
Achillea Millefolium.
Adonis vernalis.
Agave.
Alyssum saxatile.
Amaryllis.
Anchusa italica.
Anemone japonica.
Anthemis tinctoria.
Antigonon leptopus.
Aquilegia.
Arabis alpina.
Arenaria grandiflora.
Armeria vulgaris.
Artemisia.
Arundo Donax.
Asclepias.
Asters, grandiflorus, etc.
Astilbe chinensis.
Astilbe japonica.
*Astragalus tennesseensis.
Bamboo.
Baptisia australis.
Belamcanda chinensis.
Bocconia cordata.
Boltonia.
Caladium esculentum.
Callirhoë involucrata.
Campanula.
Canna.
Centaurea.
Chrysanthemums.
Clematis.
Clerodendron macrosiphon.
Coreopsis lanceolata.
Coronilla.
Crinum.
Dahlia.
Dianthus barbatus.
Dianthus deltoides.
Dianthus latifolius.
Dianthus plumarius.
Dictamnus albus.

**Astragalus tennesseensis,* Gray, from Tenn. and Ala. Hirsute: fls. in a short spike or head, cream-color, often tinged with purple: fr. pointed, strongly wrinkled. April, May.

L. A. Berckmans.

Herbs for California (mostly perennial).

Border or low edging plants.

The following plants produce the appearance of neatness and finish by more clearly defining edges of beds, walks or drives, and by serving as connecting elements between taller plants and the greensward. In so doing they may also screen the lower, more or less bare leafless stems of other plants.

Achillea santolinoides.
Agrostis nebulosa.
Allium neapolitanum.
Alyssum maritimum.
Alyssum saxatile.
Arabis alpina.
Armeria vulgaris (A. maritima).
Asperula odorata.
Aubrietia deltoidea var. græca.
Aubrietia deltoidea var. Leichtlinii.
Baeria chrysostoma var. gracilis. Thrives in sunshine.
Begonia Erfordii.
Bellis perennis, English Daisy
Bulbs of various kinds.
Calendula officinalis, Pot Marigold.
Cerastium tomentosum.
Chænostoma hispidum.
Chrysanthemum Tchihatchewii, Turfing Daisy.
Convolvulus mauritanicus.
Dianthus, Pinks.
D. barbatus, Sweet William.
Echinopsis Eyriesii.
Erigeron mucronatus, Mexican Daisy.
Festuca glauca.
Freesia.
Gazania splendens.
Geranium, Ivy.
Geranium, Madam Salleroi.
Godetia, dwarf.
Gypsophila muralis.
Gypsophila paniculata, Baby's Breath.
Helianthemum vulgare var. mutabile, Sun Rose.
Heuchera sanguinea, Coral Bells.
Iberis sempervirens, Evergreen Candytuft.
Impatiens Sultani.
Iresine Lindenii (Achyranthes acuminata).
Iris, small blue.
Kalanchoë flammea.
Lantana, dwarf.
Lobelia Erinus.
Lotus Bertholetii (L. peliorhyncus), Coral Gem.
Mahernia verticillata (M. odorata), Honey Bells.
Marigold, African (Tagetes erecta).
Marigold, French (Tagetes patula).
Mesembryanthemum cordifolium, Dew Plant.
Mignonette (Reseda odorata).
Moræa iridioides, Natal Lily.
Myosotis, Forget-me-not.
Nasturtium, dwarf.
Œnothera ovata, Sun-Cups.
Œnothera rosea, Mexican Primrose.
Omphalodes linifolia.
Ophiopogon japonicus.
Oxalis.
Oxalis cernua.
Oxalis oregana.
Oxalis purpurea.
Oxalis tetraphylla.
Pansy.
Pennisetum villosum (P. longistylum).
Phlox, dwarf.
Portulaca grandiflora, Rose Moss.
Primula.
Primula malacoides, pink.
Santolina Chamæcyparissus, Lavender Cotton.
Sanvitalia procumbens var. flore-pleno.
Saxifraga crassifolia.
Scilla.
Scirpus cernuus. For shade.
Sempervivum globiferum, Hen-and-Chickens.
Specularia Speculum (Campanula Speculum), Venus' Looking-Glass.
Specularia Speculum var. procumbens.
Spergula.
Stachys alpina.
Stachys lanata.
Sweet Pea, Cupid.
Vinca minor.
Viola cornuta.
Viola odorata.
Viola odorata, Marie Louise.
Viola odorata, Princess of Wales.
Zaluzianskya selaginoides (Nycterinia selaginoides).
Zinnia, dwarf.

For dry places.

The following are fairly drought-resistant and may be grown in dry situations, where they will bloom freely with little attention.

Abronia umbellata.
Achillea santolinoides.
Antirrhinum Coulterianum.*
Argemone platyceras.
Artichoke (Cynara Scolymus).

**Antirrhinum Coulterianum*, Benth., of S. Calif., 2–4 ft., has spicate infl and rather large corolla with protuberant yellowish palate; violet-purple or white: the slender branches and the linear or oval lvs. act as support for the plant.

For dry places, continued.

Bidens ferulæfolia*.
Calla lily (Zantedeschia æthiopica).
Cheiranthus Cheiri, Wallflower.
Cistus, Rock-Rose.
Coreopsis lanceolata.
Coreopsis tinctoria.
Cornflower (Centaurea Cyanus).
Cotyledon.
Crassula.
Encelia californica.
Eriogonum fasciculatum.
Eriogonum latifolium.
Eriogonum umbellatum.
Eschscholtzia californica, California Poppy.
Gazania splendens.
Gilia californica.
Gilia chamissonis.
Godetia grandiflora.
Goldenrod (Solidago californica).
Helianthus annuus, Sunflower.
Helichrysum petiolatum.
Heliopsis lævis var. Pitcheriana.
Kniphofia Uvaria, Red-hot-poker Plant.
Layia elegans, Tidy-Tips.
Layia glandulosa, White Daisy.
Lippia repens.
Lupinus arboreus, Yellow Tree Lupin.
Marigold, French and African.
Mentzelia Lindleyi.
Mesembryanthemum.
Mimulus brevipes, Yellow Monkey-Flower.
Mimulus glutinosus, Sticky Monkey-Flower.
Nasturtium (Tropæolum).
Nigella damascena, Love-in-a-Mist.
Ophiopogon japonicus.
Pelargonium.
Pentstemon antirrhinoides.
Pentstemon gloxinioides.
Pentstemon heterophyllus.
Pentstemon spectabilis.
Petunia hybrida.
Phacelia grandiflora.
Phacelia Whitlavia.
Romneya Coulteri, Matilija Poppy.
Romneya trichocalyx.
Salvia carduacea, Thistle Sage.
Sansevieria zeylanica, Bowstring Hemp.
Scabiosa atropurpurea, Mourning Bride.
Sedum acre.
Sedum album.
Sedum Anacampseros.
Sedum nicæense.
Sedum pulchellum.
Sedum spectabile.
Shirley poppies (Papaver Rhœas).
Trichostema lanatum.
Turfing Daisy (Chrysanthemum Tchihatchewii).
Verbenas.
Wild flowers of many kinds.
Zauschneria californica, California Fuchsia.

**Bidens ferulæfolia*, DC., from Mex., although perennial, blooms the first year from seed. It has bright orange-yellow rather small heads, and very finely cut pinnatisect or pinnate lvs., the ultimate segms. small and linear or linear-oblong: plant diffuse, the sts. 16–30 in. long. B.M. 2059.

Cut-flowers and greenery.

The following plants are well adapted for use in a garden when quantities of flowers and greenery are wanted for interior decoration and other purposes.

Adiantum Croweanum.
Adiantum cuneatum.
Adiantum gracillimum.
Adiantum grandiceps.
Allium neapolitanum.
Amaryllis.
Anemone japonica.
Anthemis tinctoria.
Antirrhinum majus, Snapdragon.
Asparagus plumosus.
Asparagus scandens var. deflexus.
Asparagus Sprengeri.
Asperula hexaphylla.
Aster, China.
Bellflower (Campanula).
Bermuda lily (Lilium).
Bidens ferulæfolia.
Bleeding-heart (Dicentra).
Boltonia latisquama.
Brake, common (Pteris aquilina).
Briza maxima.
Bromus brizæformis.
Browallia demissa.
Calceolaria.
Calla lily.
California wild flowers.
Campanula Medium.
Campanula Medium var. calycanthema.
Campanula persicifolia.
Candytuft.
Canna.
Carnation.
Centaurea imperialis, Sweet Sultan.
Chrysanthemum, pompons.
Clarkia.
Coreopsis tinctoria.
Cornflower (Centaurea Cyanus).
Cosmos.
Cyclamen.
Daffodil.
Dahlia.
Delphinium cardinale.
Doronicum caucasicum.
Erythronium.
Eschscholtzia californica, California Poppy.
Euphorbia corollata.
Everlasting flowers.
Felicia amelloides.
Ferns, Maidenhair and Sword-Fern.
Feverfew, double white.
Gaillardia aristata.
Gaillardia aristata var. grandiflora, var. maxima.
Gaillardia picta, Lorenziana, amblyodon.
Galax.
Geranium, scarlet.
Gerbera Jamesonii, Transvaal Daisy.
Geum coccineum.
Gilia liniflora.
Gladiolus.
Godetia.
Goldenrod (Solidago).
Gypsophila paniculata.
Helenium autumnale var. pumilum.
Heliopsis lævis var. Pitcheriana.
Heliotrope (Heliotropium).
Hesperis matronalis.
Heuchera rubescens.
Hollyhock.
Honesty (Lunaria annua).
Hunnemannia fumariæfolia, Mexican Poppy.
Hydrangea hortensis.
Iberis sempervirens.
Indian pink.
Iris.
Iris lævigata (Kaempferi), Japanese Iris.
Ixia.
Kniphofia Uvaria, Red-hot-poker Plant.
Larkspur (Delphinium).

Cut-flowers and greenery, continued.

Lilium Humboldtii.
Lily, Bermuda.
Lily-of-the-Valley (Convallaria majalis).
Maidenhair fern (Adiantum).
Marguerite (Chrysanthemum frutescens).
Marigold, African (Tagetes erecta).
Marigold, French (Tagetes patula).
Mexican ivy (Vancouveria hexandra).
Mignonette (Reseda).
Mimulus.
Myosotis, Forget-me-not.
Narcissus.
Nasturtium (Tropæolum).
Nigella.
Orchids (Cattleya and others).
Panicum atrosanguineum.
Panicum plicatum.
Pansy.
Pentstemon.
Petunia, double and single.
Phlox Drummondii.
Phlox grandiflora.
Pink (Dianthus).
Polygala apopetala.
Poppy.
Russelia juncea var. Lemoinei.
Russelia sarmentosa (R. multiflora).
Salvia azurea var. grandiflora.
Salvia, scarlet.
Scabiosa, Mourning-Bride.
Schizanthus.
Scilla.
Shasta daisy.
Smilax.
Snapdragon (Antirrhinum).
Snowflake (Leucojum).
Statice fruticans (S. arborea).
Statice Suworowi.
Stock.
Sunflower (Helianthus).
Sweet alyssum.
Sweet pea.
Sweet sultan (Centaurea).
Tritonia crocosmæflora.
Tuberose.
Tulip.
Verbena.
Vinca, white with red eyes, pure white.
Violet.
Volutarella muricata (Amberboa muricata).
Water-lily.
Woodwardia.
Zinnia grandiflora.

Herbaceous hedge plants (some of them shrubby).

The following plants range from 1½ to 3 to 4 feet high and may be used to give a profusion of color and brightness to a home place; to make low boundary lines between property lines; partially to hide some disagreeable object; to give a touch of privacy about some garden feature; to plant around a vegetable-garden to make it more attractive; they are very effective treated as temporary plant material.

Achillea santolinoides.
Artichoke (Cynara Scolymus).
Atriplex Breweri.
Calceolaria integrifolia.
Calla lily (Zantedeschia).
Eriogonum fasciculatum.
Feverfew (Chrysanthemum Parthenium).
Fuchsia arborescens.
Fuchsia corymbifolia.
Geranium.
Helichrysum petiolatum (Gnaphalium lanatum).
Heliotrope, Queen Marguerite.
Lantana, Dwarf.
Lantana Sellowiana.
Lavandula vera, Lavender.
Leonotis Leonurus, Lion's-Tail.
Mahernia verticillata, Honey-Bells.
Malvaviscus mollis.
Marguerite (Chrysanthemum frutescens).
Pelargonium.
Rock rose (Cistus).
Rosemary (Rosmarinus officinalis).
Salvia splendens.
Santolina Chamæcyparissus.
Streptosolen Jamesonii.
Teucrium fruticans.
Valerian, red (Centranthus ruber).
White valerian (Centranthus ruber var. albus).

For naturalizing.

Plants that will grow year after year without much attention, and therefore good to naturalize and leave alone.

Aquilegia truncata.
Aquilegia vulgaris var. nivea.
Brodiæa.
Calochortus.
Camassia Cusickii.
Camassia esculenta.
Camassia Leichtlinii.
Ceratostigma plumbaginoides.
Cow parsnip (Heracleum lanatum).
Cynoglossum grande.
Daffodil.
Delphinium nudicaule.
Dicentra spectabilis.
Dwarf bamboo.
Eriogonum.
Erythronium californicum.
Ferns.
Freesia refracta var. alba.
Iris.
Micromeria Chamissonis, Yerba Buena.
Mimulus glutinosus.
Narcissus.
Nierembergia rivularis.
Œnothera ovata.
Pentstemon barbatus var. Torreyi.
Pentstemon, California Blue-Bedder.
Saxifraga crassifolia.

Moist soil, bogs, or edges of water.

For wet grounds, bogs or near edges of water the following have been found to be successful.

Achillea Ptarmica, The Pearl.
Anemopsis californica, Yerba Mansa.
Aquilegia eximia (probably a form of *A. formosa*).
Boykinia occidentalis.*

Moist soils, bogs, or edges of water, continued.

Calla lily (Zantedeschia).
Calochortus nitidus.
Camassia Cusickii.
Camassia esculenta.
Camassia Leichtlinii.
Cat-tail (Typha latifolia).
Cyperus alternifolius, Umbrella Plant.
Cyperus alternifolius var. gracilis.
Cyperus Papyrus, Papyrus.
Cypripedium californicum, Lady's Slipper. A rare bog-plant.
Dodecatheon Jeffreyi, Shooting Star.
Elephant's Ear (Colocasia antiquorum var. esculenta; Caladium esculentum).
Epipactis Royleana. Banks or in moist soil.
Gunnera chilensis (G. scabra).
Hemerocallis aurantiaca.
Hemerocallis aurantiaca var major.
Hemerocallis Thunbergii.
Iris lævigata (I. Kaempferi).
Iris orientalis (I. ochroleuca).
Miscanthus sinensis (Eulalia japonica).
Miscanthus sinensis var. gracillimus.
Miscanthus sinensis var. variegatus.
Miscanthus sinensis var. zebrinus.
Nierembergia rivularis.
Pampas-grass (Cortaderia argentea).
Rudbeckia nitida.
Sagittaria sagittæfolia.
Tolmiea Menziesii.
Tule (Scirpus lacustris var. occidentalis).
Water-cress (Nasturtium officinale).

Almost continuous bloomers in some parts of California.

The following plants are almost continuous bloomers; i.e., flowers usually can be had most of the year in most parts of California.

Alyssum maritimum, Sweet Alyssum.
Anchusa capensis.
Begonia Erfordii.
Begonia gracilis.
Begonia semperflorens var. Vernon.
Begonia luminosa (a garden form).
Bidens ferulæfolia.
Canna.
Carnation, Corbett.
Chænostoma hispidum.
Convolvulus floridus or Rhodorhiza florida.
Convolvulus mauritanicus.
Cuphea hyssopifolia.
Cuphea ignea.
Cuphea Llavea.
Cuphea micropetala.
Dwarf lantana.
Erigeron mucronatus.
Erigeron speciosus.
Eschscholtzia californica.
Felicia amelloides.
Feverfew (Chrysanthemum Parthenium).
Geraniums, Ivy-leaved, Chas. Turner, Etincelant, Carlos Uhden, Gringoire, Leopard.
Geranium sanguineum.
Gerbera Jamesonii.
Geum, Mrs. Bradshaw.
Heliotrope, La Duse.
Heliotrope, Queen Marguerite.
Hemerocallis aurantiaca.
Hollyhock (Althæa rosea).
Marguerite (Chrysanthemum frutescens).
Pelargonium odoratissimum, Nutmeg Geranium.
Pennisetum Ruppellii.
Pentstemon antirrhinoides.
Pentstemon gloxinioides.
Petunia hybrida.
Primula obconica.
Primula sinensis.
Saxifraga crassifolia.
Shasta daisy.
Snapdragon.
Statice macrophylla.
Stokesia cyanea.
Vinca rosea.

Rock-gardens in shade.

A selection from the following will enable one to bring into the garden some of the dainty beauty of wildwood plants:

Aquilegia.
Asarum caudatum.
Boykinia occidentalis.
Epimedium.
Fuchsia procumbens.
Heuchera micrantha.
Heuchera pilosissima.
Heuchera rubescens.
Heuchera sanguinea.
Linaria Cymbalaria, Kenilworth Ivy.
Micromeria Chamissonis, Yerba Buena.
Myosotis, Forget-me-Not.
Nierembergia rivularis.
Oxalis oregana.
Phlox subulata.
Primula kewensis.
Primula malacoides.
Primula obconica.
Primula sinensis.
Sagina subulata.
Saxifraga crassifolia.
Saxifraga integrifolia.
Saxifraga Mertensiana.
Saxifraga sarmentosa.
Saxifraga umbrosa.
Tellima grandiflora.
Tiarella unifoliata.
Tolmiea Menziesii.
Vancouveria hexandra.
Vancouveria parviflora.

For shady places.

Many plants that grow freely in the direct rays of the sun in middle California, require shade in southern California and must be protected from the fierce summer heat of the Sacramento and San Joaquin valleys. Therefore, plant them under lath-houses or in the shade of trees or on the north side of a house.

Acanthus Caroli-Alexandræ.
Acanthus mollis.
Acanthus mollis var. latifolius.
Acanthus spinosus.
Aconitum, Monkshood.
Agapanthus umbellatus.
Allium neapolitanum.
Alsophila australis.
Alyssum saxatile.
Amomum Cardamon.
Anemone japonica.

**Boykinia occidentalis*, Torr. & Gray. Calif. to Wash. Erect or declined 1–2 ft.: lvs. round-cordate, 3–9-lobed: fls. many, the petals white.

For shady places, continued.

Anemone japonica var. alba.
Anemone coronaria.
Anemone fulgens.
Aquilegia, Columbine.
Asarum caudatum.
Asparagus crispus (A. decumbens).
Asparagus asparagoides, Smilax of florists.
Asparagus plumosus.
Asparagus plumosus var. comorensis.
Asparagus plumosus var. nanus.
Asparagus plumosus var. robustus (A. Hatcheri).
Asparagus plumosus var. tenuissimus.
Asparagus retrofractus.
Asparagus scandens var. deflexus.
Asparagus Sprengeri.
Asperula odorata, Woodruff.
Aspidistra lurida.
Asystasia bella (Mackaya bella).
Balm, Moldavian (Dracocephalum Moldavica).
Begonia argenteo-guttata.
Begonia coccinea (B. rubra).
Begonia Erfordii.
Begonia floribunda (a garden form).
Begonia fuchsioides.
Begonia luminosa.
Begonia Margaritæ.
Begonia nitida var. odorata alba.
Begonia Rex.
Begonia rosea.
Begonia rubella.
Begonia Sandersonii (B. Digswelliana).
Begonia semperflorens.
Begonia Templinii.
Begonia weltoniensis.
Bellis perennis, English daisy.
Calla lily (Zantedeschia).
Cibotium Barometz, Scythian Lamb.
Cinerarias.
Clivia miniata. It will not stand frost.
Convolvulus mauritanicus.
Crinum Moorei.
Cyclamen.
Cyperus alternifolius.
Cyrtomium falcatum.
Dædalacanthus nervosus.
Daffodil.
Dicentra spectabilis, Bleeding Heart.
Digitalis purpurea, Foxglove.
Dog's-tooth violet (Erythronium californicum).
Doronicum magnificum.
Eremurus Elwesii.
Eremurus himalaicus.
Eremurus robustus.
Erigeron mucronatus.
Felicia amelloides.
Ferns.
Foxglove (Digitalis purpurea).
Haworthia atrovirens.
Haworthia cymbiformis.
Haworthia margaritifera.
Haworthia rugosa.
Helleborus niger, Christmas Rose.
Heuchera micrantha.
Heuchera pilosissima.
Hyacinth.
Linaria Cymbalaria, Kenilworth Ivy.
Kniphofia Uvaria, Red-hot-poker Plant.
Larkspur (Delphinium nudicaule).
Lily (Lilium).
Lily-of-the-Valley (Convallaria majalis).
Mentha piperita.
Mimulus glutinosus.
Myosotis, Forget-me-not.
Nephrolepis exaltata var. bostoniensis.
New Zealand Flax (Phormium tenax).
Œnothera cæspitosa.
Onychium japonicum.
Oxalis oregana.
Pansy (Viola).
Papaver heterophylla.
Pentstemon cordifolius.
Pæonia.
Petasites palmata.
Pilea microphylla, Artillery Plant.
Primula (P. obconica).
Pteris cretica albo-lineata.
Pteris quadriaurita argyræa.
Pteris tremula.
Salvia patens.
Saxifraga crassifolia.
Saxifraga umbrosa.
Senecio Kaempferi aureo-maculatus.
Star Flower (Trientalis europæa var. latifolia).
Star of Bethlehem (Tellima affinis).
Solomon's Seal, False (Smilacina amplexicaulis; also S. sessilifolia).
Thalictrum Delavayi.
Tiarella unifoliata.
Tradescantia fluminensis.
Trillium.
Tulip. Shade one-third to one-half day.
Vancouveria hexandra.
Vancouveria parviflora. For partial shade.
Violet (Viola odorata). For half shade.
Wallflower (Cheiranthus Cheiri). For partial shade.

Rock-gardens in the sun.

For rock-gardens in the sun, many interesting plants may be grown, instead of the more gaudy succulents and curious desert plants.

Alyssum saxatile.
Aubrietia deltoidea var. Leichtlinii.
Calandrinia umbellata.
Cerastium tomentosum.
Chænostoma hispidum.
Convolvulus mauritanicus.
Cotyledon.
Crassula.
Echeveria.
Edelweiss (Leontopodium alpinum).
Eriogonum.
Flax (Linum).
Gazania splendens.
Geranium sanguineum.
Geum chiloense.
Geum coccineum.
Helichrysum petiolatum (Gnaphalium lanatum).
Lewisia Cotyledon.
Lewisia Howellii.
Lewisia Leana.
Lewisia oppositifolia (Calandrinia).
Lewisia rediviva.
Lewisia Tweedyi.
Lychnis Haageana.
Mahernia verticillata.
Nierembergia gracilis.
Œnothera, America.
Œnothera ovata, Sun-Cups.
Othonna capensis.
Pentstemon cæruleus.
Pentstemon Menziesii.
Santolina Chamæcyparissus, Lavender Cotton.
Sanvitalia procumbens.
Sedum.
Statice.
Synthyris rotundifolia.

John Wm. Gregg.
R. T. Stevens.
Katherine D. Jones.

HERBÉRTIA (Wm. Herbert, 1778–1847, Dean of Manchester, distinguished botanist, author of "Amaryllidaceæ," and ardent lover of bulbs). *Iridàceæ.* Bulbous plants, native from Texas to Chile and southern Brazil, with fugitive blue or lilac flowers borne in summer; allied to Tigridia.

Stems simple or forking, from a tunicated corm: lvs. mostly basal, few, long and narrow, somewhat folded or plicate: fls. several from a single terminal spathe, pedicelled; perianth showy, without tube and segms. 6 in 2 very unlike series, the inner being much smaller; stamens 3, united by their filaments into a tube; ovary long, 3-celled; styles partially united, the 3 branches forked: fr. an oblong loculicidally 3-valved exserted caps., with many small angled seeds.—About a half-dozen species, of secondary value horticulturally. There is some confusion in the generic name; but the situation is: Herbertia, Sweet, 1827; Alophia, Herbert, 1838; Trifurcia, Herbert, 1840. The herbertias thrive in usual garden soils; sometimes started in coldframes; prop. by seeds and offsets.

pulchélla, Sweet. Bulb or corm globose, ½in. or more thick; tunics brown: lvs. about 4, linear, plaited, 3–6 in. long: spathes 1½ in. long: fls. lilac; outer segms. obovate, with a white claw spotted lilac. Chile, Argentina, Brazil. B.M. 3862.

platénsis, Hort. Franceschi. Bulb or corm very large: lvs. sword-shaped, glaucescent, ribbed, 2 ft. and more long: scapes to 4 ft.; fls. large, light porcelain-blue, produced in 8 months of summer. La Plata.

H. amatòrum, C. H. Wright. Bulb or corm globose, with brown scales: lvs. lanceolate, acuminate, plicate, 8 in. long: scape 18 in., very slender, branched: spathes herbaceous, the inner twice longer than outer: fls. violet; perianth 2 in. across; outer segms. with white midrib inside, 3 times longer than inner, the latter brown-spotted at base. Uruguay.—*H. cærùlea,* Herb.=H. Drummondiana.—*H. Drummondiàna,* Herb. Corm small and ovoid, with brown tunics: st. 1 ft. or less high, simple or forked; fls. blue, 2 in. across; outer segms. obovate, with white claw; inner segms. oblanceolate, acute. Prairies, Texas. B.M. 3862.—*H. Wátsonii,* Baker. Lower: fls. purple; outer segms. oblanceolate, 1 in.; inner segms. obovate, ¼in. long. Damp prairies, Texas.

L. H. B.

HERBS, Pot: *Greens.* **Salad:** *Greens and Salad Plants.*

HERCULES' CLUB: *Aralia spinosa;* also *Zanthoxylum Clava-Herculis.*

HERÍNCQUIA: *Gesneria.* The plant once known in horticultural literature as *H. floribunda* is probably *Gesneria libanensis.*

HERITIÈRA (Charles Louis L'Heritier de Brutelle, 1746–1800, French botanist). *Sterculiàceæ.* About 4 species of trees on the tropical seacoasts of the Old World, little known horticulturally: lvs. thick, simple, entire, silvery or shining beneath: fls. small, unisexual, in axillary panicles; calyx 4–6-toothed or -cleft; petals none; stamens united into a column, bearing 5 anthers at top; ovaries mostly 5, nearly free, bearing short style and 5 stigmas: carpels woody and indehiscent when ripe, cornered, keeled or winged. Called "looking-glass tree," from the shining under-surface of the lvs. *H. littoràlis,* Dry. Moderate-sized tree: lvs. oblong, acute, 3–8 in. long: staminate fls. small, in axillary branched clusters, with an urn-shaped downy calyx; pistillate fls. larger with bell-shaped calyx: carpels or follicles 1–4 in. long, smooth or tubercled. Afr., Asia, Pacific islands.

L. H. B.

HERMÁNNIA (Paul Hermann, 1646–1695, botanical traveler, professor of medicine at Leyden). *Sterculiàceæ.* Shrubs, mostly small, growing chiefly in Afr., but a few in Amer. from Texas south, some 150 species in all. They are little known horticulturally. Lvs. alternate, entire, toothed or pinnatifid, sometimes laciniate: fls. many, yellow, orange, cream-color or reddish, on axillary peduncles or panicled; calyx campanulate, 5-cleft, often inflated, without involucre; petals 5, clawed; stamens 5, standing opposite the petals, the filaments joined at the base: fr. a coriaceous 5-celled and 5-valved many-seeded caps. *H. texàna,* Gray, occurs in dry or rocky places in Texas and adjacent Mex.: 2–4 ft.: lvs. tomentose, suborbicular to oval, serrate or dentate: fls. dull scarlet or crimson. *H. cándicans*, Ait., is a variable species of S. Afr.: erect or diffuse, tomentose: lvs. long-petioled, elliptic or ovate-oblong, obtuse, nearly entire: fls. more or less tomentose, bright yellow, the petals twice as long as calyx. Gn. 71, p. 15, where the name "cowslip bush" is proposed, its fls. closely resembling those of a small cowslip; blooms spring to fall. Other species of Hermannia are likely to be mentioned in horticultural literature.

L. H. B.

HERMINIÈRA (name refers to the stout thorns and stamens). *Leguminòsæ.* One species, in Trop. Afr.: by some included in Æschynomene. Fls. papilionaceous; calyx 2-lipped; standard orbicular, short-clawed; wings about equaling the standard, obliquely obovate; keel broad, obtuse or somewhat beaked: pod linear and nearly flat, curved spirally, separating at the square articulations. *H. Elaphróxylon*, Guill. & Perr. (*Æschynómene Elaphróxylon*, Taub.), the ambash or pith-tree of the upper Nile and beyond, may possibly be planted somewhere in our region: erect thorny shrub, to 20 ft.: lvs. bristly; lfts. 10–20 pairs, ½in. or less long, linear-oblong: fls. bright orange, subcorymbose, the peduncles bristly; standard 1½ in. broad. G.W. 14, p. 605.—It grows in wet places, sometimes choking streams.

L. H. B.

HERMODÁCTYLUS (Greek, *Mercury's* or *Hermes' fingers;* from the arrangement of the tubers). *Iridàceæ.* SNAKE'S-HEAD IRIS. A hardy tuberous plant closely allied to Iris, the fls. purplish black and green, of a quaint and peculiarly attractive beauty. The plant is procurable from European growers. The genus differs from Iris in the 1-celled ovary with 3 parietal placentæ; Iris has a 3-celled ovary: rootstocks digitate.—One species, S. France to Greece. Cult. of the tuberous irises. Flowers April, May.

tuberòsus, Salisb. (*Íris tuberòsa*, Linn.). Tubers 2–4, about 1 in. long: st. 1-fld., 1 ft. or more high: lvs. 2–3, glaucous, 4-angled, 1–2 ft. long: spathe usually with only 1 large lanceolate valve: outer perianth-segms. 2 in. long, black-purple; inner ones green. April. B.M. 531. F.S. 11:1083. G.C. II. 23:672.—*H. longifòlius*, Sweet, is a form, according to Baker, with lvs. 3–4 ft. long; and *H. bispathàceus*, Sweet, a form with 2 valves in the spathe. *H. tuberosus* is sometimes called the "widow iris" or "mourning iris," from its fls. of apple-green and velvet-black.

J. N. GERARD.
L. H. B.†

HERNÁNDIA (Francisco Hernandez, physician to Philip II of Spain, traveled in West Indies and Mexico, 1593–1600, and wrote on natural history of Mexico). *Hernandiàceæ*, formerly included in *Lauràceæ.* JACK-IN-A-BOX. Ornamental trees, grown chiefly for their large handsome foliage.

Evergreen: lvs. alternate, long-petioled, often peltate, entire, 3–7-nerved, without stipules: fls. monœcious, small, in loose terminal corymbs or panicles; the extreme branches terminated by 3-fld. cymes with a 4–5-leaved involucre at the base; their central fls. pistillate and sessile, the lateral staminate and stalked; pistillate fls. with a lobed cupula; sepals 8–10; ovary inferior, 1-ovuled; style short, with a large lobed stigma; staminate fls. with 3–4 stamens shorter than the 6–8 sepals: fr. globose, ribbed, indehiscent, inclosed in an inflated often colored involucre.—Eight species in the tropics.

These are handsome trees with large glossy foliage and with small yellowish or greenish white flowers in terminal corymbs followed by yellowish or whitish subglobose or ovoid fruits. *H. sonora* is much used in Europe for subtropical bedding, and produces a juice that removes hairs from the face without pain. *H. ovigera* is cultivated in southern California by Franceschi, who says it has light green, glossy leaves with a red spot in the center, and large, whitish, egg-snaped fruits. Propagation by cuttings of half-ripened wood under glass, which root easily with bottom heat.

sonòra, Linn. Tree, to 60 ft.: lvs. chartaceous, ovate to oblong-ovate, usually peltate, or cordate at the base, acuminate, entire, glabrous, penninerved, 7–12 in. long: corymbs grayish tomentulose; fls. yellowish, ⅛in. across; stamens 3–4; filaments with 1 gland at the base: fr. ovoid, yellow, about 1 in. long. W. Indies.—The similar *H. Moorenhoutiana*, Guill., from the Pacific islands, has smaller, more coriaceous, palmately 3–5-nerved lvs. and larger fls. ¾in. across. B.M. 5839.

ovígera, Linn. Tree, to 40 ft.: lvs. coriaceous, broadly ovate to ovate-oblong, not peltate, acuminate, subcordate at the base, palmately 7-nerved, glabrous, 4–7 in. long: corymbs grayish tomentulose; filaments with 2 glands at the base: fr. whitish, subglobose, about 1 in. long. Trop. Asia and Afr.

ALFRED REHDER.

HERNIÀRIA (Greek; supposed to cure hernia or rupture). *Caryophyllàceæ.* HERNIARY. RUPTURE-WORT. Trailing or sprawling little small-leaved herbs, one of which is grown as a carpeter.

Herniaria has about 15 species, scattered from the Canaries to W. Asia, but all grow in sandy places, chiefly near the sea. It has no near allies of much garden value, but 2 species of Paronychia are cult. for the same purpose and are easily distinguished by general appearance. Herniaria and Paronychia are alike in their 5-parted perianth and 2 stigmas, but in Herniaria the segms. are blunt, while in Paronychia they are hooded near the apex and have a horn or small sharp point on the back near the apex. Herniaria is composed of annuals or perennials with roots of short duration, and they are all much branched, trailing plants, either glabrous or hirsute: lvs. opposite, alternate or clustered, small, entire: fls. minute, crowded in the axils; sepals, petals and stamens 5: seed solitary.

glàbra, Linn. Lvs. obovate, rarely orbicular, glabrous except a few hairs at edges, which are usually recurved: fls. small and green, in a leafy spike or the lower ones at considerable intervals. July, Aug. Eu., Asia.—A hardy herbaceous perennial which grows about 2 in. high and produces inconspicuous greenish fls. in summer. It makes a dense mat of moss-like foliage, which turns a deep bronzy red in winter. It is much used in carpet-bedding and to a less extent in rockeries and for edgings of hardy borders. Recommended for covering graves. It thrives in the poorest soils, makes a solid covering, and is by some regarded as one of the most valuable of hardy trailers. Prop. by division or seed. Grows wild in England, and is kept in many large collections of hardy plants. **H. hirsùta,** Linn., Eu., has narrow hirsute lvs.: sometimes planted.

WILHELM MILLER.

HERPÉSTIS (name refers to the creeping habit of some species). *Scrophulariàceæ.* About 60 herbs, mostly of warm and tropical parts of the world, 1 or 2 of which may be transferred to cult. grounds now and then. The name Herpestis is now given up by systematic botanists, the "nomina conservanda" of the Vienna code using Aublet's Bacopa for the genus and others adopting P. Browne's Monniera or Lamarck's Bramia. Allied to Mimulus, but differs in short corolla and in unequally toothed calyx: low herbs, blooming in summer, sometimes rather succulent: lvs. opposite: fls. small, peduncled, mostly solitary in the axils, blue, purple or white, corolla 2-lipped or nearly regular; stamens 4, didynamous, not protruding; style slender; stigma 2-lobed or capitate. *H. Monnièria*, HBK., or *Bacòpa Monnièria*, Wettst., grows near the sea and along river-banks, Md. to Texas and south: glabrous, creeping, perennial, somewhat fleshy: lvs. spatulate to cuneate, entire or sparingly toothed, sessile: fls. pale blue, about ½in. long or less, the corolla only obscurely 2-lipped. Other native species with 2-lipped corolla are *H. amplexicaùlis*, Pursh, blue; *H. rotundifòlia*, Pursh, white or pale blue; *H. nigréscens*, Benth., whitish or purplish. L. H. B.

HERPETOSPÉRMUM (name refers to some character of the seeds). *Cucurbitàceæ.* Two annual tendril-climbers, one from the Himalaya region and one from China, allied to Abobra, but differing in the usually racemose sterile fls. and the long-tubular calyx. Lvs. long-petioled, ovate, nearly entire or angled: tendrils bifid: fls. rather large, yellow; corolla broadly campanulate, very deeply parted, the segms. elliptical and entire; stamens 3, included, inserted on calyx-tube, the filaments short and free: fr. medium-size, broadly oblong and 3-angled, costate, more or less 3-valved. *H. grandiflòrum*, Cogn., from China, has been cult. abroad: lvs. broadly ovate-cordate, more or less angular, 4–5 in. long: staminate fls. 3–6 at the apex of a 3–5-in. peduncle, with large golden-yellow petals; pistillate fls. solitary or in pairs, short-stalked, slightly smaller than the staminate: fr. about 2½ in. long, densely hairy and greenish, 7–8-ribbed. *H. caudìgerum*, Wall., the other species, has very lightly crenulate ovate lvs. to 6 in. long: staminate fls. usually on twin peduncles, one single-fld. and one 5–10-fld.; pistillate fls. on stout peduncles less than 1 in. long: fr. sparsely hairy, about 3 in. long. L. H. B.

HESPERÁLOE (Latin, *western Aloe*). *Liliàceæ*, tribe *Yúcceæ.* Acaulescent plants with filiferous leaves like many yuccas, but ephemeral diurnal greenish or red flowers, recalling those of the true aloes. Cultivated somewhat in the open in warm dry regions, but elsewhere under glass. Treatment much as for agaves.

Leaves outcurved, soft-pointed, with coarse marginal threads: infl. usually few-branched; fls. oblong; filaments slender, attached to base of perianth; pistil with ovoid ovary, slender style and small stigma: caps. 3-celled, 6-valved, rugose, beaked; seeds thin, flat and smooth.—Two species from Texas to Mex.

parviflòra, Coult. (*H. yuccæfòlia*, Engelm. *Alòe yuccæfòlia*, Gray. *Yúcca parviflòra*, Torr. *Y. parvifòlia*, Hemsl.). Cespitose: lvs. concave, striate on back, 1 in. x 3–4 ft., green: infl. 3–4 ft. high, glabrous and somewhat glaucous; fls. nodding, rosy, 1¼ in. long; style exserted: caps. round, 1 in. long. S. W. Texas. Rep. Mo. Bot. Gard. 13:1, 85.—With more bell-shaped fls. 1 in. long, and scarcely protruding style it is var. **Éngelmannii,** Trel. (*H. Éngelmannii*, Krauskopf). G.C. II. 18:199. B.M. 7723. Rep. Mo. Bot. Gard. 13:1.

funífera, Trel. (*H. Dàvyi*, Baker. *Yúcca funífera*, Koch. *Agàve funífera*, Lem.). Larger: infl. 6–8 ft. high; fls. purplish green, 1 in. long; style scarcely protruding: caps. 1–2 in. long. N. Mex.—The source of Zamandoque fiber, one of the kinds of "Tampico hemp." William Trelease.

HESPERÁNTHA (Greek, *evening flower*). *Iridàceæ.* Bulbs, sometimes grown indoors.

These plants belong to the Ixia tribe and are much inferior to ixias for general cult., but have fragrant fls., opening at evening; the style is short with long subulate branches, and the spathe-valves are green rather than brown. The genus is still more closely allied to Geissorhiza, and differs in having shorter style and longer style-branches and spathe-valves always green instead of sometimes brownish above. The corms are ½in. thick or less: lvs. 2–5, narrow and distichous: fls. 2–10 in a lax, distichous spike; perianth rotate and a cylindrical tube; inner segms. white; outer ones red outside; stamens inserted on the throat.—Species about 40, in Trop. Afr. and the Cape, mostly the latter. For cult. see *Ixia* and *Bulbs.*

A. *Foliage hairy.*

pilòsa, Ker. Corm globose: lvs. 2, linear, erect, strongly ribbed, 3–6 in. long: st. slender, erect, 6–12 in.: outer segms. claret-red or green. B.M. 1475 (outer segms. speckled with color).

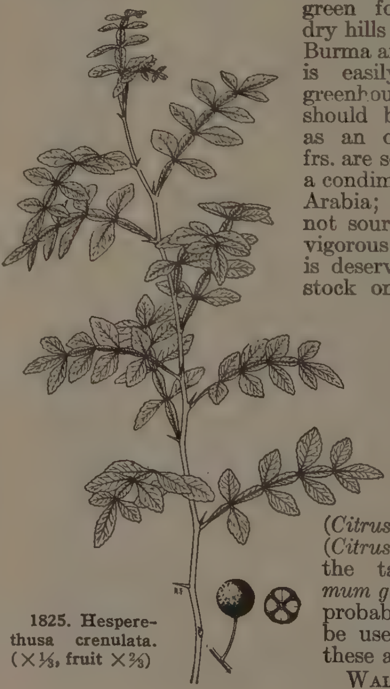
AA. *Foliage not hairy.*

falcàta, Ker. Corm conic: lvs. 2–4, lanceolate, spreading, 2–3 in. long: st. slender, 1 ft. or less, simple or forked: outer segms. claret-red. B.M. 566 (as *Ixia falcata*).

graminifòlia, Sweet. Corm globose: lvs. 3–5, linear, erect, 4–6 in. long: st. slender, 1 ft. or less, simple or rarely forked: outer segms. reddish brown or reddish green outside. B.M. 1255 (as *Geissorhiza setacea*). L. H. B.

HESPERETHÙSA (from Latin *Hesperethusa*, one of the Hesperides). *Rutàceæ*, tribe *Cìtreæ.* A slender, spiny tree or shrub: lvs. persistent, pinnate: fls. 4-merous; stamens 8, free: frs. small, 4-celled, a single seed in each cell but with no pulp-vesicles; seeds hard and rounded, cotyledons epigeous in germination: the first foliage-lvs. simple, opposite.—Only 1 species is now recognized.

crenulàta, Roem. (*Limònia crenulàta*, Roxbg. *L. acidíssima*, Auct., not Linn.) Naibel. Fig. 1825. Lvs. 5–9-foliate, the lfts., winged petiole and broadly winged segms. of the rachis crenate-margined: fls. small, white, fragrant, 4-merous; ovary 4-celled, 1 ovule in each cell: frs. small (⅓–½in. diam.), globose, dark-colored when ripe, containing 1–4 hard smooth seeds imbedded in a scanty very bitter pulp which is not composed of pulp-vesicles: cotyledons epigeous in germination, remaining small, caducous: first foliage-lvs. simple, opposite, ovate, crenate-margined. Ill. Roxbg. Pl. Corom. 1:60, pl. 86. Talbot, For. fl. Bombay, p. 198, fig. 121.—This plant is usually but erroneously called *Limonia acidissima*, Linn., which name was originally applied to the wood-apple, *Feronia Limonia*, Swingle, which see. The genus Limonia is invalid and hence the oldest valid name for this plant is the one used here. A handsome spiny shrub or small tree with beautiful light green foliage, native to dry hills in Ceylon, India, Burma and Indochina. It is easily grown under greenhouse conditions and should be better known as an ornamental. The frs. are sometimes used as a condiment in India and Arabia; they are bitter, not sour. The tree has a vigorous root-system and is deserving of trial as a stock on which to graft citrous fruit trees. In the greenhouses of the Dept. of Agric. at Washington, D. C., it has been found to grow readily when grafted on grapefruit (*Citrus grandis*), lemon (*Citrus Limonia*) and on the tabog (*Chætospermum glutinosa*) and it is probable that it could be used as a stock for these and other species. Walter T. Swingle.



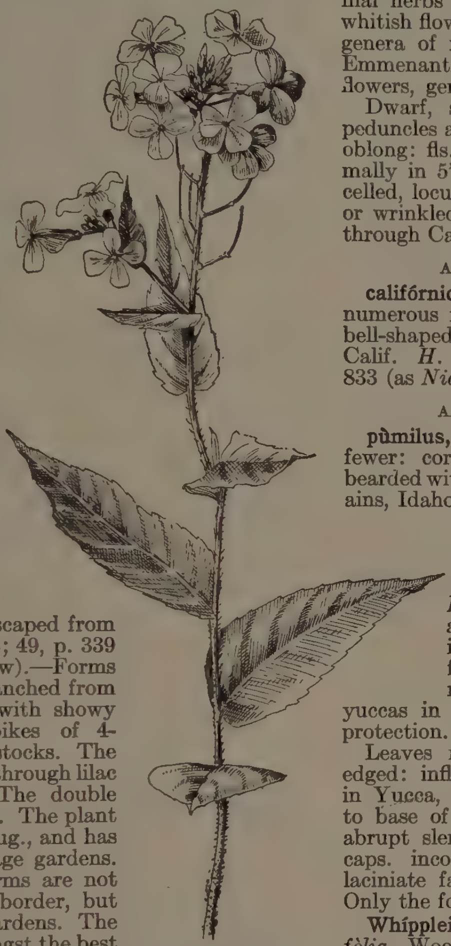
1825. Hesperethusa crenulata. (×⅓, fruit ×⅔)

HÉSPERIS (Greek, *evening*, same root as vesper; flowers more fragrant at evening). *Cruciferæ*. This includes the dame's rocket, a vigorous old-fashioned hardy herbaceous perennial.

Herbs, biennial or with a st. that is perennial at the base, pilose, the hairs simple, forked or glandular: st.-lvs. usually sparse, ovate or oblong, entire, dentate or lyrate: fls. white or purple, in loose racemes, often fragrant; petals 4, long-clawed; stigma lobed and erect: pods long, linear, cylindrical or nearly so; seeds in 1 row in each cell, usually wingless. The genus is allied to the stocks, but has a somewhat different habit and the cotyledons incumbent not accumbent.—Species about 2 dozen in the Medit. region to Cent. Asia.

matronàlis, Linn. ROCKET. SWEET ROCKET. DAME'S VIOLET. DAMASK VIOLET. Fig. 1826. Lvs. ovate-lanceolate, 2–3 in. long, toothed: pods 2–4 in. long, straight, much contracted between the seeds. Eu., N. Asia. Escaped from gardens. Gn. 53, p. 293; 49, p. 339 (a lovely garden view).—Forms clumps 2–3 ft. high, branched from the base, and covered with showy terminal pyramidal spikes of 4-petaled fls. resembling stocks. The colors range from white through lilac and pink to purple. The double forms are most popular. The plant blooms from June to Aug., and has long been cult. in cottage gardens. The ordinary single forms are not worth growing in the border, but may be used in wild gardens. The double rockets are amongst the best hardy plants, very productive of bloom and useful for cutting. The double-fld. white, var. **álba-plèna**, Hort., very fragrant, is much prized. G. 25:283; 28:701. Gn. W. 22. suppl. Apr. 29. Var. **purpùrea**, Hort., is a purple-fld. garden form. Var. **pùmila**, Hort., is a dwarf form. Var. **nàna candidíssima**, Hort., is a pure white garden form.

WILHELM MILLER.
L. H. B.†



1826. Dame's Rocket or sweet rocket—Hesperis matronalis. (×½)

HESPEROCÁLLIS (Greek, *evening beauty*). *Liliaceæ*. Leafy stemmed bulbous plant of the Colorado desert, and the desert sections of southern California, sometimes planted in California and elsewhere.

Of the tribe Hemerocallideæ, and characterized by Watson as having a large white perianth cleft to below the middle, the segms. several-nerved: anthers linear: caps. ovate-oblong, deeply lobed: fls. few in a raceme, the stout pedicels jointed at the top; seeds many, horizontal, flattened, black.—One species.

undulàta, Gray. Bulb large, corm-like: st. stout, 1–2 ft. high, 5–8-fld.: lvs. linear, fleshy, keeled, 3–6 lines wide, wavy margined: fls. 1½–2 in. long; style exserted: caps. ⅓in. long.—The fls. very fragrant, waxy-white or greenish; bulb should be deeply planted. L. H. B.

HESPEROCHÌRON (Greek, *hesperos*, originally evening, but here western, i.e., in the direction of the setting sun, and *Chiron*, a centaur distinguished for his knowledge of plants; hence "Western Centaury," these plants being at first placed in the Gentian family). *Hydrophyllàceæ*. Northwest American tufted perennial herbs with scapes bearing solitary, rather large whitish flowers, ¾ inch or less long. The nearest allied genera of recognized garden value are Phacelia and Emmenanthe, which are very distinct in color of flowers, general appearance and cymose inflorescence.

Dwarf, stemless perennials or possibly biennials: peduncles all radical and 1-fld.: lvs. entire, spatulate or oblong: fls. purplish or nearly white, with parts normally in 5's rarely in 6's to 7's; style 2-cut: caps. 1-celled, loculicidal, 15–20-seeded; seeds minutely netted or wrinkled.—Two species that have been procurable through Californian specialists and collectors.

A. *Corolla-lobes shorter than the tube.*

califórnicus, Wats. (*Capnòrea nàna*, Raf.). Lvs. numerous in a radical tuft: corolla somewhat oblong bell-shaped. Hills and meadows, Utah to Wash. and Calif. *H. latifòlius*, Kellogg, is a large form. B.R. 833 (as *Nicotiana nana*).

AA. *Corolla-lobes longer than the tube.*

pùmilus, Porter (*Capnòrea pùmila*, Greene). Lvs. fewer: corolla nearly wheel-shaped; tube densely bearded within. Springy and marshy grounds in mountains, Idaho and E. Wash. to Calif.

WILHELM MILLER.

HESPEROSCÓRDUM: *Brodiæa.*

HESPEROYÚCCA (Latin, *western yucca*). *Liliàceæ*, tribe *Yúcceæ*. Yucca-like nearly acaulescent plants, forming a very characteristic feature of the coast-range flora of California when in bloom. Hardy only in mild regions: frequently planted out-of-doors like yuccas in California, but elsewhere requiring house protection. Cultivated much like agaves.

Leaves narrow, rigid, pungently pointed, rough-edged: infl. panicled; fls. vespertine, cup-shaped as in Yucca, usually white; filaments clavate, attached to base of perianth; pistil with short oblong ovary, abrupt slender style, and fimbriate capitate stigma: caps. incompletely 6-celled, 3-valved through the laciniate false septa; seeds thin, flat and smooth.—Only the following species:

Whípplei, Baker (*Yúcca Whípplei*, Torr. *Y. graminifòlia*, Wood. *Y. Ortgiesiàna*, Roezl. *Y. califórnica*, Groenl.). Simple or cespitose: lvs. more or less 3-sided, finely striate, rough-edged, ½in. x 1–3 ft., glaucous: infl. 6–15 ft. high, oblong, long-peduncled, glabrous; fls. nodding, fragrant: caps. broad, 2 in. long. S. Calif. G.C. II. 6:197. Gn. 35, p. 561. R.H. 1886, p. 63. B.M. 7662 Rep. Mo. Bot. Gard. 3:11, 12, 54; 4:17, 23; 13:4, 5, 85.—With extremely glaucous lvs. it is var. **glaùca**, Hort. With decidedly violet-shaded fls. it is var. **violàcea** (*Y. Whípplei violàcea*, André). R.H. 1884:324. G.C. III. 39:154; 51:106 and suppl. With flatter, broader and smoother-edged lvs. it is var. **nítida** (*Y. nítida*, Wright). G.C. III. 39:153. G. 30:33. Gn. 69, p. 161.

WILLIAM TRELEASE.

HETERANTHÈRA (name refers to the unlike or different anthers). *Pontederiàceæ*. A few American bog herbs, one of which now and then occurs in horticultural literature. Sts. creeping, ascending or floating: lvs. long-stalked, grass-like or the blades ovate, oval or reniform: fls. white, blue or yellow, small, arising from the sheathing base of the petiole; perianth with slender tube, the segms. narrow and nearly or quite equal; stamens 3, unequal or equal: fr. a 1-celled or 3-celled caps. inclosed in the withered perianth-tube. *H. limòsa*, Willd., has blue fls.: spathe 1-fld.: lvs. oblong to lance-oblong, obtuse. *H. renifórmis,* R. & P., has smaller white or pale blue fls.: spathe 3–5-fld.: lvs. orbicular-reniform to cordate, acute. Both these species have unequal anthers. *H. dùbia,* MacM., has equal anthers and small pale yellow fls. All these are natives in E. U. S. and southward, and are useful for transferring to wet grounds and shallow pools. L. H. B.

HETEROCÉNTRON (*unlike spurs,* referring to structure of anthers). *Melastomàceæ.* Includes *Heeria* of Schlechtendal, not of Meissner. About 6 Mexican and Central American species, sometimes grown under glass.

Herbs or shrubs, erect or prostrate, with opposite membranaceous pinnately nerved (rarely 3-nerved) entire lvs., and white, rose or purple irregular fls. in panicles or rarely solitary: stamens 8, very unequal, the 4 larger ones with long appendages or connections; ovary loculed; petals 4.—Not to be confounded with Centradenia, which has winged sts. unequal-sided lvs., and calyx-teeth small and much shorter than the calyx-tube.—Warmhouse plants, requiring the cult. of centradenia, but grown chiefly for the fls., whereas centradenias are grown also for foliage.

ròseum, A. Br. (*H. mexicànum,* Naudin. *Heèria ròsea,* Triana) is the only species in general cult.: 1 ft. or more high, with 4-angled (but not winged) st.: lvs. elliptic, obtuse or acute, pinnate-nerved: fls. bright rose, in a large, terminal panicle, showy, in autumn and early winter. B.M. 5166. I.H. 3:97. Var. **álba,** Hook., is a white-fld. form.

subtriplinérvium, A. Br. (*Heèria subtriplinérvia,* Triana). Little branched, the branches sharply 4-angled, the young foliage and calyx sparsely pilose: lvs. oblong-lanceolate, acute at apex, narrowed into long petiole, the margin entire, blade 9–13-nerved: fls. white, the petals broadly obovate with retuse apex. Mex.

H. élegans, O. Kuntze (Heeria elegans, Schlecht. H. procumbens, Naudin), will be found under Schizocentron. L. H. B.

HETERÓMELES: *Photinia.*

HETEROPÁPPUS (Greek, *two kinds of pappus*). *Compósitæ.* A hardy herbaceous perennial that bears azure-blue aster-like flowers in summer.

Herbs, erect, branched above: lvs. alternate, entire or coarsely toothed: heads in loose irregular panicles or solitary at the tips of branches, rays white or sky-blue. The genus is closely related to Aster, having the habit of the asters of the section Calimeris. The plant in the trade is known as *Calimeris tatarica.* Heteropappus is closely related to Boltonia and is not far from Callistephus, which contains the China asters. The chief botanical distinction resides in the pappus, which in the large group containing Callistephus and Aster is composed of numerous bristles arranged in one or more series, while Boltonia and Heteropappus belong to a group in which the pappus is anomalous. In Boltonia it is composed of very short, somewhat chaffy bristles, with the addition usually of 2–4 awns not longer than the achene. In Heteropappus the pappus of the rays is composed of very short, somewhat chaffy bristles, while in the disk-fls. it consists of numerous slender bristles arranged in 1 or 2 series.—A genus of 2–4 species from Japan and China.

híspidus, Less. (*Calímeris tatárica,* Lindl. *Áster híspidus,* Thunb.). St. roughish: lvs. linear, acute, pubescent and ciliated on the margins: branches spreading, usually unbranched and bearing 1 head: involucral scales acuminate, hirsute, herbaceous, not white-margined, rays blue. Japan, Mongolia. L. H. B.

HETEROPHRÁGMA (Greek, *different* and *septum;* alluding to the peculiar 4-angled septum of the typical species). *Bignoniàceæ.* Three species of E. Indian trees, with large opposite pinnate lvs. and large yellow or pink fls. in terminal panicles or from the old wood: calyx campanulate, irregularly 3–5-lobed; corolla campanulate-funnelform; ovules in several series in each cell of the broadly linear ovary: caps. cylindric or compressed, falcate or twisted, loculicidally 2-valved; septum flat or 4-angled. The 2 African species referred by some writers to this genus belong to Fernandia. Only the following species has been offered in this country. **H. adenophýllum,** Seem. (*Bignònia adenophýlla,* Wall.). Tree, 30–50 ft.: young growth tomentose: lfts. 5–7, broadly elliptic, acute or obtuse, entire, tomentose, 7–9 in. long: fls. in terminal panicles; calyx irregularly 5-lobed; corolla brownish yellow, densely woolly outside, with spreading 5-lobed limb, 2 in. wide: caps. twisted, resembling a cork-screw, 1–3 ft. long; septum flat. Wight, Ill. 160 (as *Spathodea adenophylla*).—Little known in cult. and adapted for subtropical or tropical countries only. Prop. probably like Radermachia by cuttings and air-layering.

ALFRED REHDER.

HETERÓPTERIS (*various winged,* referring to the fr.). *Malpighiàceæ.* Shrubs, erect or rarely climbing, of Trop. Amer. and 1 in W. Afr. Fls. small, yellow or purple, in panicles or racemes: lvs. opposite, nearly or quite entire. The calyx is 5-parted, some or all the lobes with a pair of sessile glands; petals clawed; stamens 10, all perfect but unequal; ovary 3-celled, with 3 subulate styles, the stigma on an angle of the style: fr. 1–3 samaras, with a somewhat semi-circular wing.—Species 90 or more. The climbing species may be found in choice collections. *H. purpùrea,* Kunth, is a low climber among shrubs, according to Grisebach, in the farther W. Indies and Venezuela: lvs. oval, glabrous, somewhat glaucous beneath, the petiole with 2 glands at the middle: fls. purple, corymbose or racemose, on slender pedicels that are jointed below the middle: fr. 1 in. long, with semi-obovate oblique wings. *H. chrysophýlla,* HBK. Twining: lvs. oval or oval-oblong, entire, glabrous above and golden pubescent beneath: fls. orange, becoming reddish. Brazil. B.M. 3237. An interesting plant for the warmhouse, long-climbing. L. H. B.

HETEROSMÌLAX (Greek, *another kind of Smilax*). *Liliàceæ.* This includes an ornamental climber with the habit of smilax, but the perianth is undivided (instead of 6-parted, as in smilax) and the mouth is minutely 2–5-dentate. It resembles smilax in having diœcious fls. borne in umbels, and tendril-bearing petioles. The genus contains 5 species of woody climbers from India, Malaya, China and Japan: lvs. 3–5-nerved: fls. small or very small. Little known culturally outside the far East.

japónica, Kunth. Lvs. with stalks about ½in. long, blades about 4–5 in. long. Japan, where it is cult. for the roots, which are used in medicine: Hemsley writes that it is said to have been intro. into Japan from China but that no Chinese specimens are known to exist (1903). L. H. B.

HETEROSPÀTHE (Greek, a *different kind of spathe*). Also written *Heterospatha.* *Palmàceæ,* tribe *Arèceæ.* A rare and highly ornamental palm, with graceful, spreading habit and pinnatisect leaves, the segments being long, slender and tapering.

Its nearest allies of garden value are Verschaffeltia and Dypsis, in which the stigmas are basal in fr., while Heterospatha belongs to a group in which the stigmas are eccentric or lateral in fr. Other important generic characters are the 6 stamens with versatile anthers and the 1-celled ovary.—Only 1 species, native of the small island of Amboyna, the Dutch headquarters in the E. Indies. Intro. from the Java botanic garden in 1879 to England. The plant is procurable from importers and from S. Fla., but is cult. in Amer. only in botanic gardens.

LIV. Herbs and shrubs employed about a pond.

elàta, Scheff. (*Metróxylon elàtum,* Hort.). Tall, unarmed: lvs. terminal, long-petioled, equally pinnatisect; segms. numerous, lanceolate, narrowed at both ends, acuminate, 1-nerved, margins thickened and recurved at the base; rachis round on the back, flat on the face; sheath short, fibrous, swelled at the base: spathes 2, the lower 2-crested, the upper much longer.—A very worthy palm, valuable chiefly for its graceful habit while still quite young. Must be grown in a moist hot house. N. Taylor.†

HETERÓTOMA (name refers to the unequally cut corolla). *Campanulàceæ.* About 10 species of Mexican annuals and perennials, one of which has come somewhat into cult. Lvs. alternate: fls. blue, yellow or orange, in terminal racemes; calyx tubular with an unequally 5-parted limb, the 2 anterior lobes usually adnate to the spur of the corolla; corolla-tube split to the base on the back, in front produced into a horizontal or deflexed spur, the limb short and incurved and with either nearly equal or unequal lobes; stamen-tube free from corolla; ovary inferior, 2-celled, many-ovuled: caps. 2-valved. **H. lobelioìdes,** Zucc. Erect, branching, the st. pubescent: lvs. alternate, ovate-lanceolate, distantly toothed, acuminate: fls. about 2 in. long, single on slender axillary peduncles, odd; corolla-spur blood-red, the limb golden yellow and 3-lobed; lower lip of calyx adnate to the corolla-tube and the 2 subulate green lobes projecting beyond it; staminal column erect, as long as the corolla-limb, and prominent. Mountains in Mex. and Cent. Amer. B.M. 7849. R.H. 1905, p. 9.—An interesting showy perennial, sometimes called "bird flower," to be grown in a cool greenhouse in winter and in the open in summer. L. H. B.

HETERÓTRICHUM (name refers to the *variable hairs* on the lvs.). *Melastomàceæ.* Ten or a dozen hispid, or glandular shrubs in Trop. Amer., with white or pink fls. in terminal or lateral panicles; calyx campanulate or globular, with 4–8 teeth; corolla of 6–8 petals; stamens 8–12 or more: lvs. large, ovate or oblong, cordate at base, entire or toothed. *H. mácrodon,* Planch., is sometimes mentioned in horticultural literature. A very handsome shrub, 7–9 ft., flowering when small: lvs. opposite, large, the 2 in the pair unequal, cordate-ovate, abruptly acuminate, serrate, 7-nerved: fls. 10–12 in a terminal cyme, white with red at base of petals, 1¾ in. across, the 8 petals obovate and flat-spreading; calyx and young parts hispid or villous. Venezuela. B.M. 4421. G.W. 14, p. 652.—Requires hothouse treatment. L. H. B.

HEÙCHERA (Johann Heinrich von Heucher, 1677–1747, professor of botany at Wittenberg). *Saxifragàceæ.* Herbs resembling the dainty wild flower, the bishop's cap (Mitella) in their habit, as they have a tuft of heart-shaped, five- to nine-lobed, crenate leaves, from which spring a dozen or so slender scapes a foot or more high with small flowers borne in panicles, giving a delicate and airy effect. This includes *H. sanguinea* which probably ranks among the best low perennials with small, red flowers. It is very desirable for the hardy border, where it blooms from spring to late fall. It is also useful to florists for cut-flowers and autumn forcing.

Heuchera belongs to a group of genera including Mitella and Tiarella, in which the ovary is 1-celled. There is a well-developed hypanthium often bell-shaped, sometimes urceolate, cylindrical, turbinate, or saucer-shaped, often more or less oblique, and adnate to the lower part of the pistil. Most of the distinguishing characters of this difficult genus are found in the shape of the hypanthium. In Heuchera the petals are 5 or none, and entire; in Mitella 5, 3-fid or pinnatifid; in Tiarella 5 and entire. Heuchera has 5 stamens; Mitella 5 or 10; Tiarella 10. The caps. of Heuchera is inferior, 2-beaked; in Mitella superior, not beaked; in Tiarella superior, compressed.—Heuchera has 72 species, all N. American and ranging from Mex. to the arctic regions. A full botanical treatment is by P. A. Rydberg, in N. Amer. Flora. 22:97–117 (1905), which has been followed in the account below. Many of the species are distinguished only by rather technical botanical characters, but only a few of them are known horticulturally.

The attractive and petal-like part of *H. sanguinea* is the calyx, the petals being small in all heucheras (often shorter than the calyx). The other species are attractive by reason of their general habit, and particularly the graceful, open panicle. *H. sanguinea* came into prominence about 1884 and is now deservedly one of the most popular of hardy perennials. The others are procurable from the largest dealers in native plants and from western collectors. They range from 3 inches to 3 feet high, averaging about 1½ feet, and bloom in summer, having greenish white or purplish flowers. Almost any good garden soil suits them, and they are not particular as regards exposure to sunlight (though an open situation is preferable); and they look well in borders, rockeries, separate beds and elsewhere. Propagate by division or seed.

KEY TO THE SPECIES.

A. *Stamens equaling or exceeding the sepals.*

B. *Panicle open, not spike-like.*

C. *Hypanthium not strongly oblique.*

D. *Breadth af hypanthium about as the length.*

E. *Lobes of the lf.-blade broadly triangular, acute* .... 1. **villosa**

EE. *Lobes of the basal lf.-blades, at least, rounded.*

F. *The hypanthium, with the sepals 1–1½ lines long* ... 2. **micrantha**

FF. *The hypanthium, with the sepals 1½–4 lines long* .. 3. **americana**

DD. *Breadth of hypanthium about twice the length* .... 4. **rubescens**

CC. *Hypanthium strongly oblique; stamens equaling or slightly exceeding the sepals.*

D. *Flowering branches more or less leafy* .... 5. **pubescens**

DD. *Flowering branches leafless or practically so* .... 6. **hispida**

BB. *Panicle dense, contracted, almost spike-like* .... 7. **bracteata**

AA. *Stamens much shorter than the sepals.*

B. *Hypanthium and sepals 1½–2½ lines long* .... 8. **parvifolia**

BB. *Hypanthium and sepals 2½–5 lines long.*

C. *Infl. contracted and spike-like* ..... 9. **cylindrica**

CC. *Infl. open, not spike-like* ....10. **sanguinea**

1. **villòsa,** Michx. Height 1–3 ft.: lf.-blades nearly round, deeply 5–7-lobed, the lobes triangular acute: scape mostly leafless; calyx and hypanthium about 1 line long; petals pinkish, twice as long as the sepals. Rocky places, Va. to Ga. and Tenn. B.B. 2:179.—A good border plant.

2. **micrántha,** Douglas. Height 1–2 ft., the flowering branches 1–4-lvd. or almost scape-like.: lvs. slightly hairy, the blades round-cordate, about as long as broad, long-stalked: infl. glandular-hairy; petals oblanceolate whitish, not very showy. Calif. to Brit. Col. B. R

1302. R.H. 1898, p. 431.—The *H. erubescens* of the gardeners seems certainly to belong here.

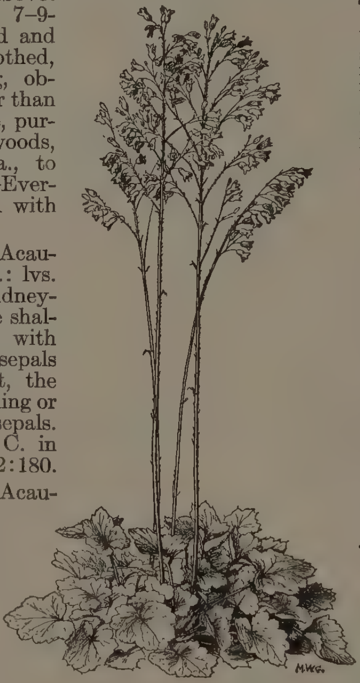
3. **americàna,** Linn. Alum Root. Height 2–3 ft.: scape leafless or with a few small lvs.: basal lvs. round-cordate, hirsute on the veins beneath, often glabrous above, at least when mature: infl. glandular hairy; the petals about equaling the sepals, greenish white; stamens at least 3 times the length of the sepals. Dry or rocky woods, Ont. to La. and Minn. B.B. 2:179. R.H. 1898, p. 431.—Has mottled foliage when young, but becomes plain green in age.

4. **rubéscens,** Torr. Acaulescent: height 8–15 in.: scape usually leafless: lvs. kidney-shaped or round-cordate, perfectly glabrous or sometimes slightly glandular, thick and often shining: sepals pinkish, green-tipped; petals almost twice as long as the sepals, linear-oblanceolate. Mountains of Utah and New Mex. to Ore and E. Calif.—Useful for the alpine-garden.

5. **pubéscens,** Pursh (*H. ribifòlia,* Fisch. & Avé-Lall. *H. rubifòlia,* Hort., also seems to belong here). Acaulescent: height 9–12 or 15 in.: scapes densely glandular pubescent, at least above: lvs. round-cordate, 7–9-lobed, the lobes broad and rounded, sharp-toothed, ciliate; sepals oblong, obtuse, somewhat shorter than the broadly spatulate, purplish petals. Rich woods, in mountains of Pa., to N. C. B. B. 2:179.—Evergreen foliage marbled with bronzy red.

6. **híspida,** Pursh. Acaulescent: height 2–4 ft.: lvs. round-cordate or kidney-shaped, 5–9-lobed, the shallow, rounded lobes with broad teeth, ciliate: sepals spatulate, very blunt, the petals spatulate, equaling or shorter than the sepals. Woods, Va. and N. C. in the mountains. B.B. 2:180.

7. **bracteàta,** Ser. Acaulescent and densely cespitose: flowering branches usually about 4–6 in. tall, usually with a few minute lvs.: basal lvs. round-kidney-shaped, more or less round-lobed and with cuspidate teeth: sepals oblong, obtuse, the petals oblanceolate or spatulate, slightly exceeding the sepals. Alpine regions of Colo. and S. Wyo.—Useful only in alpine collections.



1827. Heuchera sanguinea.

8. **parvifòlia,** Nutt. Acaulescent and cespitose: flowering branches scape-like and quite naked: lvs. kidney-shaped, usually with an open sinus, and with 7–9 shallow, rounded lobes: infl. ultimately elongated; sepals broadly ovate, somewhat shorter than the spatulate, yellowish petals. Alberta to N. Mex. and Ariz.

9. **cylíndrica,** Douglas. Acaulescent: height 10–24 in.: the infl. spike-like and naked or with a few minute bracts: lvs. round-cordate, with a few shallow lobes and ovate, cuspidate teeth; sepals oblong, the yellowish green petals minute or sometimes lacking. Brit. Col. to Ore. and Idaho.—Grown chiefly for its foliage.

10. **sanguínea,** Engelm. Coral Bells. Crimson Bells. Fig. 1827. Height 1–1½ ft.: scapes pilose below, glandular pubescent above: fls. typically bright red, but in horticultural varieties ranging from white through pink and rose to dark crimson. New Mex., Ariz. and N. Mex. Very good pictures are B.M. 6929. Gn. 26:360; also those in Gt. 45, p. 577. I.H. 43, p. 334. Mn. 8 p. 75. A.G. 17:201. R.H. 1898, p. 431. R.B. 22, p. 246. S.H. 2:120. G.C. III. 4:125. P.G. 4:35. Var. **álba** (*H. álba,* Hort.) has pure white fls., and was intro. about 1896 by Haage & Schmidt. Var. **spléndens,** intro. 1898 by the same firm, has dark crimson fls. Var. **robústa,** or **grandiflòra,** Hort., according to J. B. Keller, is an improvement on the type, the bells being larger and the color brighter. Var. **hýbrida** ("Rosy Morn"), Hort., according to D. M. Andrews, is "more robust than the type, foliage deeper cut and the divisions more pointed: fls. rosy pink." Andrews adds that var. **álba** comes true from seed. Var. **rôsea,** and var. **máxima** with dark crimson fls. are advertised. —Under the name *H. brizoides,* Hort., there is a widely cult. plant with red sts. and pale pink fls. It is chiefly interesting because it is a bigeneric hybrid, it apparently being a cross between *Heuchera sanguinea* and *Tiarella macrophylla.* It is a garden hybrid first noticed in 1897. Var. **gracíllima,** Hort., seems merely a more slender form.

The following names are seen in trade catalogues or in Rydberg's monograph: *H. convallària,* Hort. About 2½ ft., with long-stalked panicles of fls. somewhat like the lily-of-the-valley. There is a pink-fld. form, *H. cárnea.*=(?)—*H. cristàta* has been listed in Calif. as "a wonderfully pretty crested variety, originated by Luther Burbank."—*H. macrophýlla,* Hort., not Lodd., may be Tiarella macrophylla.—*H. pilosíssima,* F. Muell. 1–2 ft. high: fls. in close clusters; calyx globular. Calif.—*H. purpuráscens* was advertised 1898.—*H. Wheèleri,* Hort., was found in the S. some years ago, and resembles a form of H. canadensis with variegated lvs.—*H. Zabelliàna,* Hort., has pale pink fls. on long fl.-stalks.

N. Taylor.†

HEÚRNIA: *Huernia.*

HÈVEA (from the Brazilian name). *Euphorbiàceæ.* Tropical trees; some yield rubber and are cultivated for that reason.

Juice milky: lvs. alternate, long-petioled, the 3 lfts. entire: fls. small, monœcious, in loose panicles; calyx valvate, 5-lobed or 5-toothed; petals none; stamens 5–10, filaments united into a column; ovary 3-celled, 1 ovule in each cell: fr. a large caps.; seeds about 1 in. long.—About 17 species chiefly in the Amazon region.

The milky juice of some species is rich in caoutchouc, and they are among the most important sources of rubber; otherwise rarely cultivated except in economic and botanical collections. *H. braziliensis,* especially var. *janeirensis,* Pax, is the chief source of the South American or Para rubber. The various species are closely related and difficult to separate. The rubber plant commonly cultivated as a house-plant is *Ficus elastica.*

Damp, hot climates, such as the tropical rain forest region, without a dry season, are best suited for the culture of hevea, though it will stand some drought. It is best grown from seeds, but can be propagated by cuttings. The seed should be planted as soon as ripe, as they live but a short time. The trees grow rapidly, and attain their full height of 60 feet in about eight years, but live for many years longer. A six-year-old tree will yield as much as a pound of rubber a year and more when older. For further directions on culture, see "Cyclopedia of American Agriculture," Vol. II, p. 555. See M. T. Cook, "Diseases of Tropical Plants," p. 191, for rubber plant diseases.

brasiliénsis, Muell. Arg. South American Rubber Tree. Para Rubber Tree. Caoutchouc Tree. Brazil Rubber. Seringueira. Tree, to 60 ft. high: petioles slender, 3–10 in. long; lfts. elliptical-lanceolate, 6 in. long, straight-veined: branches of the panicle and fls. finely and closely pubescent: staminate buds acute; stamens 10 in 2 whorls. Amazon region of Brazil. Quite variable. H.I. 2573, 2575. Gn. 18, p. 564.

pauciflòra, Muell. Arg. (*H. confùsa,* Hemsl.). Tree, to 60 ft. high: lfts. obovate, cuneate, obtuse acuminate, 4–6 in. long: staminate buds obtuse; stamens 10 in 2 whorls. British Guiana. H.I. 2574, 2575.—Sometimes used for rubber.

guianénsis, Aubl. (*Siphònia Cahùchu,* Willd. *S. elástica,* Pers.). SERINGA. Tree, to 60 ft. high: lfts. obovate, base acute, apex obtuse, 3–5 in. long: panicle tomentose: staminate buds obtuse; stamens 5 in 1 whorl. French Guiana to the Amazon. H.I. 2573.—Intro. but rarely cult. for rubber. J. B. S. NORTON.

HEXACÉNTRIS: *Thunbergia.*

HEXADÉSMIA (name alludes to the 6 pollen-masses). *Orchidàceæ.* About a half-dozen Trop. American epiphytic orchids, rarely grown in hothouses. They are like Scaphyglottis, but differ in having 6 pollinia in 2 series rather than 4. The fls. are small, in fascicles or racemes: lvs. fleshy. Apparently none of the species is in the trade.

HEXASTÝLIS: *Asarum.*

HEXÌSEA (Greek, *six equal things;* because the attractive and bright-colored parts of the fls. are 6, and of equal size.) Should have been written *Hexisia. Orchidàceæ.* This includes a small epiphytic plant which was once advertised as "bearing profuse panicles of bright vermilion fls. twice a year." The genus belongs to a subtribe closely related to Epidendrum but with different pollinia. Sts. terete or angled, with usually 2 lvs. at the apex of each annual growth. New growths arise in the axils of the lvs., the entire st. being thus made up of long, fusiform, apparently superimposed pseudobulbs, with 2 lvs. at each node: lvs. few, narrow: racemes terminal, the short-peduncled furnished with overlapping, leathery scales; fls. orange or purple; anthers semi-globose; pollinia 4, in 1 series.—Four species, ranging from Mex. to Guiana.

bidentàta, Lindl. Height 6–8 in.: st. branched, forming spindle-shaped, many-grooved internodes: lvs. in pairs, 2–4 in. long, 3 lines wide, channelled, notched. Panama. B.M. 7031. G.M. 37:19.

HEINRICH HASSELBRING.

HEYDÈRIA: *Libocedrus.*

HIBBÉRTIA (George Hibbert, English patron of botany, died 1838). *Dilleniàceæ.* Shrubs or subshrubs with yellow or white showy flowers, suitable for the greenhouse or for growing in the open in the warm parts; apparently none is in the American trade.

Erect, procumbent or climbing, sometimes almost herbaceous, some species reaching 5 or 6 ft.: lvs. mostly small, entire or dentate, often heath-like, strongly 1-nerved with obscure or rarely prominent reticulations, some of them usually crowded beneath the blossoms: fls. solitary, terminal, sometimes approximating into clusters; sepals 5, sometimes united at base; petals 5, spreading and usually making an open fl.; stamens usually 12 or more, sometimes with staminodia: carpels usually 2–5, dehiscent at the top when ripe.—Species about 100, nearly all Australian, a few from Madagascar. Any of these species is likely to appear in lists, but only 2 or 3 are regularly known as horticultural subjects.

dentàta, R. Br. Woody only at base, trailing or twining, with rather large dark yellow pedunculate fls. (to 2 in. diam.): lvs. stalked, oblong, to 2 in., distantly toothed or sinuate, coppery: petals obovate, entire or nearly so; stamens slender and very numerous; staminodia present. New S. Wales and Victoria. B.M. 2338. B.R. 282. G. 32:127. L.B.C. 4:347.

perfoliàta, Hueg. Sts. trailing, procumbent, ascending or becoming erect: lvs. ovate, usually somewhat toothed, perfoliate: petals obovate, entire, pale yellow, the fls. peduncled; stamens numerous, with a few staminodia. W. Austral. B.R. 29:64. J.H. III. 43:147.

volùbilis, Andr. Sts. woody, trailing, or climbing 2–4 ft.: lvs. obovate to lanceolate, to 3 in., clasping: fls. large, yellow, somewhat fetid, sessile or nearly so; petals obovate, entire; stamens very numerous, no staminodia. Queensland and New S. Wales. B.M 449.—This and *H. dentata* are offered in England.

L. H. B.

HIBISCADÉLPHUS (brother of *Hibiscus*). *Malvàceæ.* Under this name, J. F. Rock founds three species of Hawaiian small trees; of two of the species only one individual tree is in existence, while of the third several may still be found on the slopes of Mt. Hualalai, in the forest of Waihau, in North Kona, Hawaii. From Hibiscus the genus differs in the deciduous calyx and other floral characters: fls. 2½ in. or less long, yellowish, magenta, or green: lvs. cordate, unevenly 3–5-pointed or rounded and entire. *H. Giffardiànus,* Rock, is a medium-sized tree with peculiarly shaped deep magenta fls. and cordate-orbicular lvs.; a single tree known in 1913 and in danger of extinction. *H. Wilderiànus,* Rock, is a tree 15–18 ft. high with yellowish fls. and 3-lobed wavy lvs. of orbicular outline; one tree known in 1912 and in a dying condition, one on which the collector was able to find 1 open fl. and a few more or less developed buds. *H. hualalaiénsis,* Rock, has green fls. somewhat reddish inside, and somewhat reniform lvs.; a few trees are still in existence. These rare trees are not in the trade, but they are likely to appear in collections in the tropics if they can be rescued before destruction. See Rock, "Indigenous Trees of the Hawaiian Islands." L. H. B.

HIBÍSCUS (old Latin name). Including *Abelmóschus* and *Paritium. Malvàceæ.* ROSE-MALLOW. Showy-flowered garden and greenhouse herbs and shrubs; in the tropics some of them are trees.

Hibiscus is a polymorphous genus, allied to Gossypium, Abutilon, Althæa and Malva, the species widely distributed in temperate and tropical countries: herbs or shrubs, or even trees, with lvs. palmately veined or parted: parts of the fl. in 5's; calyx gamosepalous, 5-toothed or 5-cleft, subtended by an involucel of narrow bracteoles; corolla usually campanulate, showy, of 5 distinct petals; stamens united into a 5-toothed column; ovary 5-loculed, bearing 5 styles: fr. a dry, more or less dehiscent caps (Fig. 1828).—Between 150 and 200 species, of which perhaps 20 occur in the U. S. Horticulturally, there are 4 general groups of Hibiscus—the annuals, the perennial border herbs, the hardy shrubs, and the glasshouse shrubs, to which might be added the tree-like species of tropical countries that are often planted along roadsides and about dwellings. The perennial herbaceous species are among the boldest subjects for planting in remote borders or in roomy places, particularly in soil that is damp. These plants, of the *H. Moscheutos* type, are commonly known as marsh-mallows, but this name properly belongs to *Althæa officinalis.*

1828. Capsule of Hibiscus syriacus.

In recent years, improved and valuable hardy forms of the native herbaceous rose-mallows have been introduced. They bloom throughout a long season. (Fig. 1829.) The Meehan Mallow Marvels were introduced in 1905, the first successful cross having been made in 1898. They are stated to be hybrids of *H. coccineus, H. militaris,* and *H. Moscheutos.* They are in pink, shades of red, and white; the flowers often have an eye of different color. The Giant-flowering marsh-mallows of Bobbink & Atkins, now catalogued as *H. Moscheutos* hybrids, were first offered in 1909 at retail and in

1911 to the trade. They are stated to be hybrids of *H. coccineus* and *H. Moscheutos*, the first cross being made in 1905, first plant flowered in 1906. The colors range from white to crimson, sometimes with an eye.

The culture of such a various group as hibiscus cannot be described in detail. In general, the species present no special difficulties. They are strong and profuse growers, and mostly thrive under a variety of conditions.—The herbaceous perennial species are late summer and fall bloomers, with hollyhock-like flowers. They send up new strong shoots or canes each year. Many of them are perfectly hardy in the North, but even these profit by a mulch covering. Others are tender in the North, and the roots should be taken up after frost and stored in a dry, warm cellar. Keep them just moist enough to maintain life in them. Many times the roots of these herbaceous species are set in large pots in the spring, and they then make excellent specimens. All the species require a deep rich soil and a good unfailing supply of moisture.—The only popular glasshouse species in this country is *H. Rosa-sinensis*, a showy and floriferous summer bloomer, of many varieties. The culture of this species is indicated under No. 28.

1829. A garden rose-mallow. White. (×⅙)

KEY TO THE SPECIES.

A. *Plant annual or biennial (sometimes perennial in the case of Nos 3 and 6).*
  B. *Habit low and diffuse* .... 1. **Trionum**
  BB. *Habit erect, the plants mostly tall, strict and stout.*
    C. *Calyx 5-cleft, not ventricose or spathe-like.*
      D. *St. not prickly* .... 2. **Sabdariffa**
      DD. *St. prickly* .... 3. **cannabinus**
    CC. *Calyx long and spathe-like, splitting on one side, deciduous.*
      D. *Bracteoles linear.*
        E. *Caps. short (3 in. or less)* ..... 4. **Abelmoschus**
        EE. *Caps. long and large (5 in. or more)* .... 5. **esculentus**
      DD. *Bracteoles broad and leafy* ...... 6. **Manihot**
AA. *Plant obviously perennial, herbaceous (or sometimes woody below).*
  B. *Branches and petioles prickly* .... 7. **diversifolius**
  BB. *Branches and petioles not prickly.*
    C. *Bracteoles lobed or forked* .... 8. **aculeatus**
    CC. *Bracteoles entire, not enlarged at apex.*
      D. *Foliage glabrous or essentially so.*
        E. *Lvs. toothed or lobed* .... 9. **militaris**
        EE. *Lvs. deeply divided* ....10. **coccineus**
      DD. *Foliage pubescent or tomentose.*
        E. *Calyx-lobes ovate or ovate-lanceolate.*
          F. *Lvs. hastately 3-lobed* ......11. **grandiflorus**
          FF. *Lvs. only obscurely angle-lobed* ....12. **lasiocarpus**
        EE. *Calyx-lobes with triangular outline.*
          F. *Fls. rose-color* ....13. **Moscheutos**
          FF. *Fls. white with reddish center* ....14. **oculiroseus**
        EEE. *Calyx-lobes ovate to triangular-lanceolate; fls. often yellow*.15. **incanus**
AAA. *Plant distinctly woody, being a shrub or a tree.*
  B. *Branches and petioles prickly. (No. 18 may sometimes lack prickles.)*
    C. *Fls. yellow* ....16. **radiatus**
    CC. *Fls. pink* ....17. **cisplatinus**
    CCC. *Fls. white* ....18. **heterophyllus**
  BB *Branches and other parts usually not prickly or spiny.*
    C. *Color of fls. on the order of yellow.*
      D. *Involucre an 8–10-toothed cup.*
        E. *Species Japanese: a shrub*...19. **Hamabo**
        EE. *Species tropical; usually small trees.*
          F. *The involucre deciduous with the calyx*..........20. **elatus**
          FF. *The involucre persistent with the calyx*..........21. **tiliaceus**
      DD. *Involucre of 5 separate bracteoles*.....................22. **calycinus**
    CC. *Color of fls. pink, scarlet, white.*
      D. *Petals deeply cut*.............23. **schizopetalus**
      DD. *Petals entire or essentially so.*
        E. *Lf.-margins practically entire (sometimes toothed at apex), or only obscurely crenulate.*
          F. *Fls. red*.................24. **liliiflorus**
          FF. *Fls. white, axillary*.......25. **Arnottianus**
          FFF. *Fls. white, terminal*. .....26. **Denisonii**
        EE. *Lf. margins lobed or toothed.*
          G. *Lvs. downy*............27. **mutabilis**
          GG. *Lvs. essentially glabrous.*
            H. *Stamens prominently exserted*...........28. **Rosa-sinensis**
            HH. *Stamens not exserted*...29. **syriacus**

1. **Triònum**, Linn. (*H. vesicàrius*, Cav. *H. africànus*, Hort.). FLOWER-OF-AN-HOUR. BLADDER KETMIA. TRAILING HOLLYHOCK. Fig. 1830. Annual, 1–2 ft. high, bushy-spreading, the main branches becoming prostrate, usually hispid-hairy: lvs. 3–5-parted, the upper ones 3-parted, with the middle lobe much the largest, the lobes linear-oblong or sometimes widening

upward, coarsely notched, the root-lvs. undivided: fls. solitary in the upper axils, opening wide in the sunshine but closing in shadow, 1–3 in. across, sulfur-yellow or white, usually with a brown eye; pedicel elongating in fr., and the calyx becoming much inflated. Cent. Afr. B.M. 209.—An interesting annual, blooming freely throughout the hot weather of summer, and thriving in any open, warm place. Seeds are usually sown where the plants are to stand. Excellent for rock-work. It is sometimes a weed in cult. grounds. *H. Trionum* as sometimes defined, has much wider and more spatulate and relatively shorter lf.-lobes, which are round-toothed or lyrately lobed: fls. smaller: and in this case the above description would apply to *H. vesicarius;* but there seems to be insufficient reason for keeping the two distinct. Var. **màjor,** Hort., is offered: 2 ft.: fls. primrose-yellow with deep violet center.

1830. Hibiscus Trionum. (×⅓)

2. **Sabdaríffa,** Linn. (*H. rosélla,* Hort.). Jamaica Sorrel. Roselle. Strong annual, 5–7 ft. high, nearly glabrous, the sts. terete and reddish: root-lvs. ovate and undivided, the upper ones digitately 3-parted, the side lobes sometimes again lobed; lobes lanceolate-oblong and crenate-dentate: fls. solitary and almost sessile in the axils, much shorter than the long lf.-stalks; calyx and bracts red and thick, less than half the length of the yellow corolla. Old World tropics. Gn. 66, p. 428.—Widely cult. in the tropics, and now grown somewhat in S. Fla. and S. Calif. for the fleshy calyxes, which, when cooked, make an excellent sauce or jelly with the flavor of cranberry. The green seed-pod is not edible. The juice from the calyxes makes a cooling acid drink. It thrives in hot, dry climates.

3. **cannabìnus,** Linn. Annual, or sometimes perennial, the st. glabrous and prickly: lower lvs. cordate and not lobed, the upper deeply palmately lobed into narrow serrate parts: peduncle short: bracteoles 7–10, narrow: fls. large, yellow with crimson center, on very short axillary peduncles; sepals lanceolate, bristly, with gland on back of each; corolla spreading: caps. nearly globose, bristly. Old World, and widely grown for a coarse fiber which is known as "Bimlipitam jute."

4. **Abelmóschus,** Linn. (*Abelmóschus moschàtus,* Moench). Annual or biennial, 2–6 ft., hispid: lvs. various, usually palmately 5–7-lobed, the lobes spreading and oblong-lanceolate and coarsely toothed: bracteoles 6–12, linear, ¾in. or less long: fls. 4 in. diam., yellow with crimson center; calyx 15-toothed: caps. 3 in. or less long, oblong-lanceolate in outline, setose. India.—Grown in tropical countries for the musk-scented seeds, which are also sometimes used medicinally; also for the fls. Varies greatly, some of the forms having no lobed lvs.

5. **esculéntus,** Linn. (*Abelmóschus esculéntus,* Moench). Okra. Gumbo. Annual: mostly strict, 2–6 ft. or more, the sts. terete and more or less hispid: lvs. cordate in outline, 3–5-lobed or divided, the lobes ovate-pointed and coarsely toothed or notched: bracteoles very narrow, about 1 in. long: fls. solitary and axillary, on inch-long peduncles, yellow, with a red center: fr. a long ribbed pod (5–12 in. long), used in cookery. Trop. Asia.—For cult., see *Okra.* A large-fld. form (var. *speciosus,* cf. *H. Manihot*) in Gt. 43, p. 623.

6. **Mánihot,** Linn. Fig. 1831. Tall and stout (3–9 ft.), glabrous or somewhat hairy: lvs. large, palmately or pedately 5–9-parted into long and narrow oblong-lanceolate dentate lobes: bracteoles oblong-lanceolate, falling after a time (as does the calyx): fls. large (4–9 in. across), pale yellow (sometimes white), with a purple eye, very showy: caps. oblong and hispid. China and Japan; widely spread in the tropics, and naturalized in the southern states. B.M. 1702; 3152; 7752. S.H. 2:263.—This is apparently the Sunset hibiscus of the trade; also the Queen of the Summer hibiscus. In botanical works, *H. Manihot* is said to be an annual, but as known to horticulturists it is perennial in mild climates, although not persisting long and making its best bloom on young plants. For a discussion of this point as related to the limitations of the species, see G. C. III. 22:249; Gn. 53, p. 127 (and plate 1157). Botanically, the species is allied to *H. esculentus.* Not hardy in the open in the N., but the roots may be taken up in the fall and carried over winter in a warm dry cellar. In the Middle States and S., it may be expected to survive if well mulched. Grows readily from seeds, blooming late the first year if the seeds are started under glass. Var. **disséctus,** Hort., has the lvs. cut almost to the petiole into narrow lobes.

7. **diversifòlius,** Jacq. Tall and rigid, herbaceous or subshrubby, stiffly pubescent, the branches and petioles bearing stout and short conical prickles: lvs. variable, mostly broad-cordate or nearly orbicular, angular or somewhat 5-lobed, toothed: fls. in axillary or terminal racemes, primrose-yellow with dark red center; sepals linear-lanceolate, bristly; corolla much

1831. Hibiscus Manihot. (×⅙)

larger than calyx: caps. ovoid, pointed and hispid; seeds glabrous. Trop. Afr., Pacific islands, and Austral., and cult. in E. India. B.R. 381.—Offered in S. Calif.

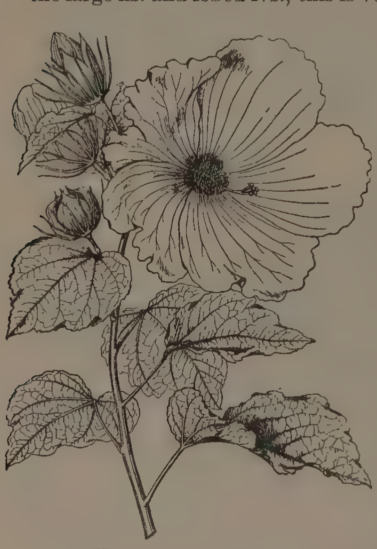
8. **aculeàtus,** Walt. Herbaceous perennial, not very stout, 2–6 ft. tall, hispid all over but not tomentose nor whitish: lvs. roundish or roundish-ovate in outline, 3–5-lobed or -parted into linear or oblanceolate cut or toothed blunt segms., the sinuses often rounded and enlarging: bracteoles 10–12, linear, forking and bristly, not so long as the calyx: fls. 3–4 in. across, yellow or cream-colored with purple in the base, the petals about 3 in. long and the calyx-lobes lanceolate and bristly. S. C. south in sand, frequently near swamps.—Not hardy N.

9. **militàris,** Cav. Herbaceous perennial, 4–6 ft., strong-growing, glabrous or very nearly so: lvs. rather small, usually hastate (2 short lobes at base), the middle lobe ovate-lanceolate or triangular-lanceolate, long-acuminate, equally crenate-toothed; upper lvs. halberd-form: bracteoles linear or awl-like, nearly or quite half as long as the calyx: fls. 3–5 in. across, white, blush or pale rose, purple-eyed: fr. inclosed in inflated calyx; seeds hairy. Wet places, Pa. to Minn. and south to the Gulf. B.M. 2385.—A hardy and fine species. Forms occur with lvs. not lobed.

10. **coccíneus,** Walt. (*H. speciòsus,* Ait.). Perennial herb, green and glabrous throughout, glaucous, 3–10 ft.: lvs. palmately lobed, or the lowest and sometimes all of them palmately compound, the divisions long-linear-lanceolate and remotely toothed: bracteoles about 1½ in. long, curved: fls. very large (5–6 in. across), rose-red, the petals obovate and conspicuously narrowed at the base; column of stamens very long. Ga. south in swamps. B.M. 360. R.H. 1858, p. 575; 1866:230.—This fine species is apparently not hardy in the northern states, although there are reports that plants have lived in the open in the neighborhood of Philadelphia. The roots should be stored in a cellar in winter. Plants have been carried over winter under glass when used in hybridizing.

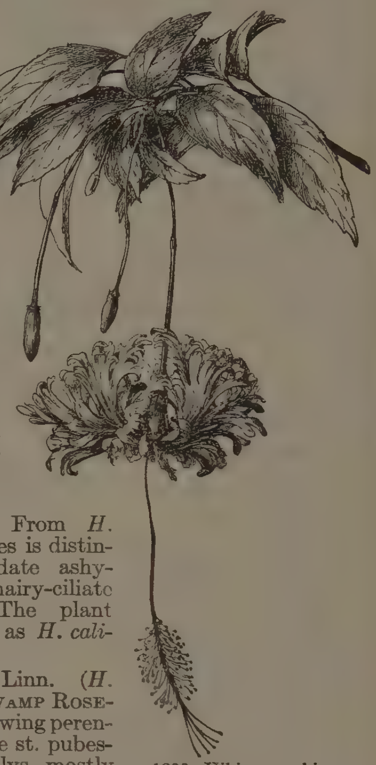
11. **grandiflòrus,** Michx. Perennial herb, tall and stout (3–8 ft.), the terete reddish st. becoming glabrous: lvs. large, 3-lobed, the lobes ovate-acuminate or ovate-oblong-acuminate, the side ones widely spreading, blunt-toothed or even again lobed: bracteoles linear, 1 in.: fls. very large (6–8 in. across), white or rose, with deeper eye. Ga., Fla. west, in swamps.—Aside from the large fls. and lobed lvs., this is very like *H. Moscheutos.* It is doubtful whether the true *H. grandiflorus* is in the trade.

12. **lasiocárpos,** Cav. Fig. 1832. Perennial herb, to 6 ft.: st.: and lvs. pubescent: lvs. ovate, more or less cordate, acuminate, toothed, often angular or slightly 3-lobed, the upper ones narrower: bracteoles linear-subulate and bristly: fls. white or pale rose with darker center, the petals 3–4 in. long: caps. very hairy. Swamps, Ky., west and south. G. F. 1:426 (reduced in Fig. 1832).



1832. Hibiscus lasiocarpos. (×⅓)

Var. **califórnicus** (*H. califórnicus,* Kell. *H. lasiocárpos* var. *occidentàlis,* Gray). Lvs. more uniformly cordate: caps. less hairy; seeds papillate: marshy places along San Joaquin and Sacramento Rivers. It is strong-growing, to 7 ft., the st. terete or slightly grooved above, more or less pubescent: lvs. distinctly cordate, ovate, acute, shallow-toothed and not lobed, dull ashy gray beneath: involucre-bracts hairy: corolla white or rose, with a purple eye, 3–5 in. across: caps. pubescent. Although the name *H. californicus* is common in the trade, it is a question how much of the stock, if any, is this species. Certainly some of it is *H. Moscheutos.* From *H. Moscheutos* this species is distinguished by its cordate ashy-tomentose lvs. and hairy-ciliate involucre-bracts. The plant known to the trade as *H. californicus* is hardy.



1833. Hibiscus schizopetalus. (×½)

13. **Moscheùtos,** Linn. (*H. palústris,* Linn.). Swamp Rose-Mallow. Strong-growing perennial 3–8 ft., the terete st. pubescent or tomentose: lvs. mostly ovate, entire in general outline or sometimes shallowly 3-lobed at the top, crenate-toothed, very soft-tomentose beneath but becoming nearly or quite glabrous above, the long petiole often joined to the peduncle: bracteoles linear, nearly or quite as long as the tomentose calyx: calyx-lobes triangular-ovate; fls. very large (4–7–8 in. broad), light rose-color: caps. globose-ovoid, glabrous. Marshes along the coast from Mass. to Fla. and west to Lake Michigan. B.M. 882. B.R. 1463; 33:7. Mn. 2:161. Gng. 2:227. F.S. 12:1233. R.H. 1907, p. 203 (as var. *palustris*). G.W. 6, p. 63. *H. ròseus,* Thore, of Europe, is considered to be a naturalized form of this American species. R.H. 1879:10.—One of the best of the rose-mallows, thriving in any good garden soil. Of easiest cult. and perfectly hardy. Blooms in Aug. and Sept. The foliage is strong and effective. The most generally cult. of the hardy herbaceous kinds.

14. **oculiròseus,** Brit. Crimson-Eye Rose-Mallow. Resembles *H. Moscheutos:* differs in fls. being white with dark crimson center, calyx-lobes triangular-lanceolate and nearly twice as long as broad, caps. ovoid-conic and long-pointed. Marshes near the coast, N. J. southward.

15. **incànus,** Wendl. Much like *H. Moscheutos,* and probably sometimes passing for it in the trade: lvs. smaller and narrower, ovate-lanceolate, rarely lobed, serrate-toothed: fls. sulfur-yellow, pink or white with a crimson eye: caps. ovoid and beaked, stellate-tomentose and loosely hairy. Md. and south in swamps.—Seems to be hardy in the N. with a mulch protection.

16. **radiàtus,** Willd. (not Cav.). Woody shrub, 3–4 ft., armed on branches and petioles with small prickles: lvs. rather narrow, deeply palmately divided, 3–5-lobed, or uppermost simple, the lobes broad-lanceo-

late and serrate; stipules linear: bracteoles 8–10, linear, forked: fls. axillary and solitary, yellow with crimson center; calyx not glandular. India, Java. Widely cult. in tropics. Var. **flòre-purpùreo,** Hook., has rose-purple fls. B. M. 5098. Var. **Líndlei** (*H. Líndlei*, Wall.) has deep purple fls. B.R. 1395.

1834. Hibiscus Rosa-sinensis. (×½)

17. **cisplátinus,** St. Hil. Bushy, 3–5 ft.: sts. glabrous but prickly: lvs. deltoid-lanceolate or deltoid-ovate, 3-lobed, coarsely toothed, sparsely hairy on the veins: fls. solitary, 4–5 in. across, light pink, with darker color in the eye and sometimes darker on the margins. Brazil (this side the Platte River, whence apparently the specific name). R.H. 1898:480. Gng. 7:50.—Little known in this country. It is a handsome late fall bloomer, and may be planted out in summer. It seeds freely, and these, sown as soon as ripe, will give blooming plants for the following fall.

18. **heterophýllus,** Vent. Tall shrub, glabrous except on infl. and very young shoots, the branches often prickly: lvs. varying from linear to lanceolate and elliptic-oblong and from entire to 3-lobed, 5–6 in. long, usually serrulate and sometimes white beneath: fls. large (3–4 in. long), white with a deep crimson eye, the calyx tomentose: caps. hairy; seeds glabrous. Austral.; intro. in S. Calif., where it is a free and showy bloomer.

19. **Hamàbo,** Sieb. & Zucc. Shrub, 6–10 ft. high, closely pubescent: lvs. roundish, with an abrupt short point, irregularly shallowly toothed, or wavy, white tomentose beneath and green or grayish hairy above: involucre of scales united at the base: fls. solitary in the upper axils, large, yellow, with a darker base, about 3 in. across.—A Japanese species offered by importers but not yet tested in this country, and probably not hardy south of the southern-middle states. Said to be cult. in Japan.

20. **elàtus,** Swartz (*Parítium elàtum*, Don). Mountain Mahoe. Spreading small tree: lvs. round-cordate, short-cuspidate, entire, hoary beneath: involucre deciduous with the calyx, 8–10-toothed: fls. 4 in. long, opening primrose-color in the morning, then changing, as the day advances, to orange and deep red: seeds hairy. W. Indies.—This species, the next, and probably others, yield the Cuba bast, used for tying cigars and for other purposes. Lvs. and shoots medicinal: wood durable.

21. **tiliàceus,** Linn. (*Parítium tiliàceum*, Juss.). Round-headed tree, 20–30 ft. high, sometimes a tall shrub: lvs. round-cordate and short-acuminate, entire or obscurely crenate, hoary beneath: involucre persistent with the calyx, 10-toothed or -cut: fls. 2–3 in. long, yellow: seeds glabrous or very nearly so. Fla. keys and W. Indies, but widespread in tropics and probably of Old World origin. Sprouts from the base if frozen.

22. **calycìnus,** Willd. (*H. chrysánthus*, Hort.). Small slender shrub: pubescent: lvs. long-stalked, round-cordate, somewhat 3–5-angled and 5–7-nerved, crenate, hairy or velvety: stipules subulate: fls. on axillary peduncles which are shorter than the petioles, large, yellow, with a dark center: involucre bracts 5, bristle-pointed: caps. tomentose. S. Afr.—To be grown indoors, but may be planted out in the summer with good results. Probably valuable for permanent planting in the extreme S.

23. **schizopétalus,** Hook. f. Fig. 1833. Tall glabrous shrub with slender drooping branches: lvs. ovate-elliptic, toothed: bracteoles minute: fls. pendulous, on long jointed peduncles, red or orange-red, the recurved petals beautifully and deeply cut; calyx tubular; stamens long-exserted: fr. long, bearing smooth seeds. E. Trop. Afr. B.M. 6524. F.S. 23:2397, 2398. G.Z. 25, p. 241.—A beautiful species, for the warmhouse; grown in the American tropics.

24. **liliiflòrus,** Cav. (*H. Genèvii*, Bojer). Shrub, glabrous: lvs. petioled, ovate, 2–4 in. long, entire or crenate, often few-toothed at apex, obtuse or acute, rounded at base, the young ones sometimes deeply parted: bracteoles 5, linear, connate at base: fls. solitary in upper axils, long-peduncled, bright red; sepals 1½ in. or less long, lanceolate, connate above the middle; corolla funnel-shaped; stamens equaling corolla or somewhat exserted. Mauritius and Seychelles Islands. B.M. 3144. — An excellent glasshouse species, of several varieties.

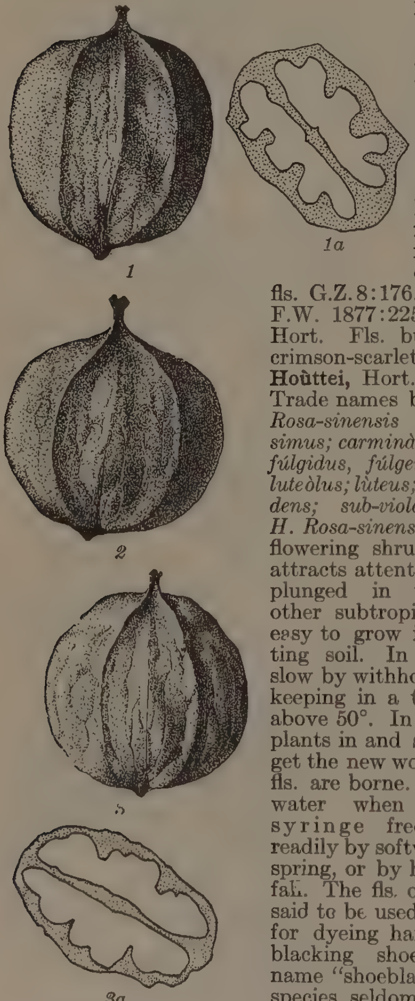
1835. Hibiscus syriacus. (×½)

25. **Arnottiànus,** Gray (*H. Faùriei*, Leveil.) Tree, 20–30 ft.: lvs. large, ovate, short-acuminate, entire, 3-nerved, stiffish, shining: bracteoles 5–7, triangular to lanceolate: fls. axillary and solitary, very large, white, sometimes with pinkish veins; calyx tubular, 5-toothed; stamens long-exserted, white or red. Hawaii; cult. there, and intro. in S. Calif.

26. **Dénisonii,** Burb. Small glasshouse shrub, flowering when very small, glabrous: lvs. thick and rather stiff, slender-stalked, elliptic-ovate, entire or obscurely crenulate, acuminate, dull green: fls. terminal, large, white, 4–5 in. across. Nativity unknown, but intro. from Austral. F.M. 1876: 232. G.Z. 22: 217.—A good greenhouse plant, requiring warm temperature; apparently little grown.

27. **mutábilis,** Linn. Tree-like: lvs. cordate, 5-angled and toothed, downy: bracteoles shorter than calyx: fls. axillary, opening white or pink but changing to deep red by night, 3–4 in. across; sepals ovate-lanceolate, joined below the middle: caps. globose, hairy; seeds hispid. China. H.F. II. 11:80.—Cult. in tropical and subtropical regions. Intro. in S. Fla. under the name of "cotton rose" and "confederate rose."

28. **Ròsa-sinénsis,** Linn. (*H. sinénsis,* Hort.). CHINESE HIBISCUS. Fig. 1834. In glasshouses a shrub 3–8 ft. high, but reaching 30 ft. in subtropical regions and becoming tree-like: glabrous: lvs. rather large, thin and shining green, broad-ovate to lance-ovate, somewhat tapering to the base, acuminate, coarsely and unequally toothed: bracteoles linear, free, as long as the calyx: fls. solitary in the upper axils of the new growth, on peduncles which exceed the petioles, bright rose-red, 4–5 in. across, with a projecting red column of stamens and pistil; sepals lanceolate, joined below the middle: caps. ovoid, glabrous, the valves terminating in a short beak. Asia, probably China: now distributed in warm countries, and one of the best known old-fashioned conservatory pot-plants, and one of the characteristic plants in tropical countries. B.M. 158. I.H. 29:441. G.C. III. 2:529. Gn. 53, p. 127.—It is now immensely variable. Forms are double-fld., and others are orange, yellow, bright red, magenta, and parti-colored. Var. **Coòperi,** Hort. (*H. Coòperi,* Hort.), has narrow white-marked lvs. and distorted scarlet fls. G.Z. 8:176. H.F. II. 6:210. F.W. 1877:225. Var. **Cálleri,** Hort. Fls. buff-yellow with crimson-scarlet base. Var. **Van Hoùttei,** Hort., deep crimson. Trade names belonging to *H. Rosa-sinensis* are *brilliantíssimus; carminàtus, chrysánthus; fúlgidus, fúlgens; kermesìnus; luteòlus; lùteus; miniàtus; spléndens; sub-violàceus; zebrìnus. H. Rosa-sinensis* is a summer-flowering shrub which always attracts attention. It is often plunged in the open with other subtropical stuff. It is easy to grow in ordinary potting soil. In winter keep it slow by withholding water and keeping in a temperature not above 50°. In spring head the plants in and start them up to get the new wood on which the fls. are borne. Give plenty of water when growing, and syringe frequently. Prop. readily by softwood cuttings in spring, or by hard cuttings in fall. The fls. of this plant are said to be used in some places for dyeing hair and also for blacking shoes, whence the name "shoeblack plant." The species seldom seeds in cultivation, although it is reported as seeding freely in some tropical regions.



1836. Forms of Carya ovata. 1, 1*a*, Meriden; 2, Jackson; 3, 3*a*, Milford.

29. **syrìacus,** Linn. (*Althæa frùtex,* Hort.). SHRUBBY ALTHEA. ROSE OF SHARON. Figs. 1828, 1835. Shrub, 6–12 ft. high, sometimes almost tree-like, much branched, nearly or quite glabrous: lvs. rather small, short-petioled, strongly 3-ribbed, triangular- or rhombic-ovate, lower ones mostly 3-lobed and with many rounded teeth or notches: bracteoles linear, 6 or 7: fls. solitary in the axils on the young wood (late in the season), short-peduncled, somewhat bell-shaped, 2–3 in. long, rose or purple, usually darker at the base; sepals ovate-lanceolate, exceeding the bracteoles: pod short, splitting into 5 valves. Asia. B.M. 83. R.H. 1845:133 (var. *speciosus,* with double fls.). Gn. 75, p. 604. J.H. III. 55:473. G.W. 13, p. 65. G.Z. 24:97. J.F. 4: pl. 370. G. 7:149; 11:167. F.E. 25:459; 32:127.—One of the commonest of ornamental shrubs, and hardy in Ontario; commonly known as althea. It is immensely variable in character of fls., the colors ranging from blue-purple to violet-red, flesh-color and white; also full double forms. There are forms with variegated lvs. Colored plates of some of the double-fld. forms will be found in Gn. 52:504. The species thrives in any good soil. Prop. by seeds, by cuttings of ripened wood taken in the fall, and named varieties by grafting on the common seedling stock. Nativity uncertain, but probably not Syrian, as Linnæus supposed: probably native in China. To this species belongs the trade name *H. Lèopoldii.* There are many horticultural forms of this interesting late summer-flowering shrub. Var. *Meèhanii,* Hort., is a variegated-lvd. form of somewhat dwarf habit, and single fls. 3–4 in. across, lavender, and purple-blotched. Other trade names that belong with *H. syriacus* are: *amplíssimus,* double, purple-pink with carmine center; *anemonæflòrus; atrórubens; bícolor,* semi-double, white with dark center; *camelliæflòrus; cœléstis; elegantíssimus; Lèopoldii; pæoniflòrus; purpùreus; ranunculæflòrus; rùber; speciòsus; tòtus álbus; violàceus.*

H. aponeùrus, Sprague & Hutch. Shrub, to 4 ft.: lvs. small, ovate or elliptic, sometimes slightly 3-lobed: fls. solitary, axillary, 1 in. across, brilliant scarlet. Trop. E. Afr. B.M. 8231.—*H. Árcheri,* Hort., is a hybrid of H. Rosa-sinensis and H. schizopetalus, raised by A. S. Archer, Antigua, W. Indies. Much like H. Rosa-sinensis. Fls. red. Gn. 55:310.—*H. Cámeronii,* Knowles & West. Tall shrub, with heart-shaped 3-lobed lvs. and large, solitary, cream-colored, red-veined fls. Madagascar. B.M. 3936. H.U. 3, p. 42. The plant figured under this name in Gn. 53:280 is probably a form of H. Rosa-sinensis.—*H. cùpreus,* Pampan. Allied to H. Rosa-sinensis: branches coppery purple in color: lvs. lanceolate, undulate and usually entire: bracteoles 6–8, linear: fls. nearly 2 in. long, purple with carmine eye. Ceylon.—*H. Kòkio,* Hildeb. Tree: lvs. ovate or elliptic-oblong, crenate, glabrous: fls. axillary and solitary, red, the petals to 2½ in. long; staminal column red, not long-exserted. Hawaii.—*H. Pátersonii,* R. Br.=Lagunaria.—*H. puníceus,* Hort., apparently has no botanical standing: still offered abroad. G.Z. 19:1.—*H. Scóttii,* Balf. Large bush or small tree from Isl. of Socotra: lvs. ovate, entire, 3-lobed, or toothed: fls. 3½ in. across, bright golden yellow with carmine eye. B.M. 7816.—*H. spléndens,* Fras. Shrub. 12–20 ft., soft-tomentose, prickly: lvs. cordate-ovate, palmately 3–5–7-lobed: fls. very large, rose-red. Austral. B.M. 3025. B.R. 1629. Handsome.—*H. suratténsis,* Linn. Trailing, with palmately 3–5-parted lvs.: fls. yellow: involucre-bracts with odd nail-like spines. India, but widely distributed. G.C. III. 9:529.—*H. venùstus,* Blume. Very like H. mutabilis, but involucre-bracts broad. Java. B.M. 7183.—*H. villòsus,* undetermined trade name.—*H. Waìmeæ,* Heller. Tree, 20–30 ft.: lvs. suborbicular, crenate, pubescent on both sides: fls. axillary near ends of branches, large, white or tinged with pink; staminal column red, long-exserted. Hawaii. G. C. III. 57:8.

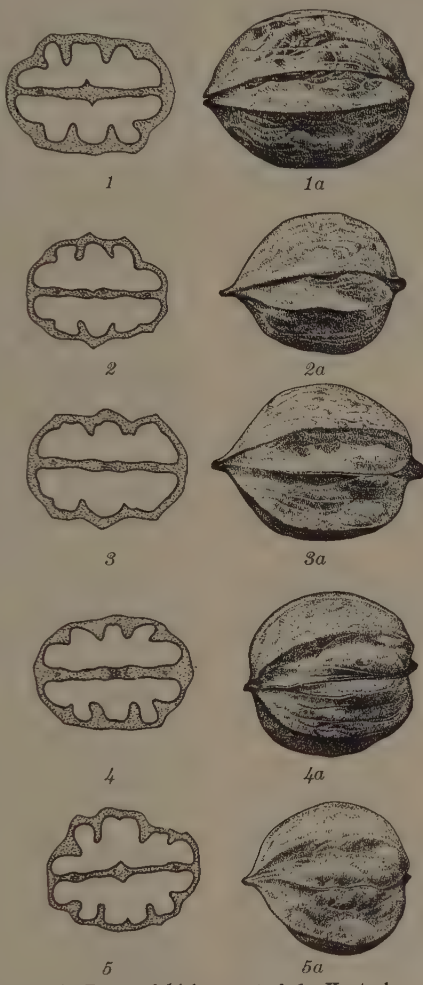
L. H. B.

HICKORY-NUT. Notwithstanding the high esteem in which the nuts of several species of hickory have been held since the settlement of America by the white men, but little progress has been made in their domestication and improvement. Out of the nine or ten species recognized by botanists, not more than three or four have been found sufficiently promising from an economic standpoint to justify conspicuous effort at amelioration. Of these the pecan (*Carya Pecan*) stands easily first, followed in order of apparent value by the shagbark (little shellbark), *C. ovata;* the shellbark (big shellbark), *C. laciniosa,* and the pignut, *C. glabra.* The pecan differs in its requirements of soil and climate from the other species, and is described separately under *Pecan*. For the botany of the hickories, see *Carya.*

In flavor and quality of kernel, the shagbark is esteemed by most Americans as the choicest of native nuts, though in these respects the shellbark is but little inferior to it. The thinner shell and larger proportion of kernel have given the former precedence over the latter in most cultural efforts; though the thrifty growth, symmetrical form and luxuriant foliage of the latter render it one of the most handsome and useful of native trees for roadside or lawn planting. The shagbark has the broader area of natural distribution, being found in localities throughout most of the United States to the eastward of the Great Plains, except on the lowlands of the South Atlantic coast and Gulf states. The shellbark is mainly confined to the valley of the Mississippi and its larger tributaries, extending eastward, however, into eastern Pennsylvania and western New York.

The pignut, which is similar to the shagbark in area of distribution, is much inferior to the others in quality, but shows wider variation than either in this respect, and has disclosed at least one variety of distinct cultural merit.

As the hickories, other than the pecan, are slow-growing species at best, they should not be planted on other than fertile soil. The shellbark is native to river bottoms, and requires richer land than the others, which endure a rather wide range of soil characteristics, provided there is sufficient depth and good drainage. Deep, well-drained fertile loams, either of sandy or clayey nature, are acceptable to all the species.



1837. Forms of hickory-nut. 1, 1a, Kentucky; 2, 2a, Kirtland; 3, 3a, Rieke; 4, 4a, Swain; 5, 5a, Weiker.

Propagation.

All the species are propagated by seed. Planting is frequently done in autumn, but, to lessen the destruction by rodents, is more safely done in early spring. In such case the freshly gathered nuts, after removal from the hulls, should be stored in slightly dampened sand during the winter or stratified, as other tree seeds. Uniformity of growth is promoted by planting nuts where trees are to stand, as the transplanting process in ordinary seasons is accompanied by a considerable loss. If trees must be transplanted, it is probably best to transplant annually in nursery rows, in rich soil, to promote growth of fibrous roots and lessen the shock of final transplanting to the permanent location.

The propagation of the hickories (except the pecan) by budding and grafting, is exceedingly difficult, even the most experienced propagators securing but a partial stand in the nursery, under favorable conditions. This fact coupled with the comparatively high mortality in transplanting such trees from the nursery has greatly retarded the dissemination of the many choice varieties that have been located in the form of seedling trees, during the past quarter-century.

One of the simplest methods of multiplying the stock of a choice tree, to a limited extent, and thus to insure the preservation of the variety, is that suggested by Fuller in his "Nut Culturist," which was apparently one of the first methods successfully employed in shagbark propagation. This consists in the "turning up or exposing at the surface of the ground of side roots, severed from the parent tree." The severed side roots are straightened up and tied to stakes to hold them in position with their cut ends about level with the surface of the ground to stimulate the formation of shoots from adventitious buds, one of which is eventually made the trunk of the new tree. The lower end of the root is not severed until the top has formed, when the new tree should be transplanted to its permanent location in rich and mellow soil and kept well mulched until thoroughly established. The method is slow and sharply limited in extent of application but is perhaps the surest in the hands of the amateur grower.

The late Jackson Dawson, the very skilful propagator of woody plants at Arnold Arboretum, achieved a considerable degree of success in propagating the shagbark by side-grafting on specially grown bitternut (*C. minima*) seedlings. He grew the seedlings in boxes 4 inches deep, for one or two years until of sufficient size for grafting. The seedlings were then transferred to pots in autumn and taken into the greenhouse about January 1. They were side-grafted, close to the collar. As soon as the roots began to start, the potted trees were plunged in sphagnum to the top bud of the cion and left until March to callus.

As improvement in method and technique in pecan-propagation has been accomplished by southern nurserymen during the past ten years, considerable attention has been given to the hickory by some of them, with the result that a certain degree of success has been attained with the annular and patch-bud methods, both in nursery propagation and top-working. Unfortunately, in many cases, the shagbark has been budded upon southern pecan seedlings, the ability of which to endure the minimum temperatures of the northern regions where the principal interest in shagbark planting exists is at least very doubtful.

The cleft-grafting of thoroughly established stocks at the crown, in early spring, has thus far proved the most practical method for the average propagator. This is accomplished by removing the earth to a depth of 3 to 4 inches from the base of the tree. The stock is cut off with a fine saw about 2 inches below the ground-line or at the top of the root-swelling. Cions having terminal buds should be inserted by either center or side-graft methods. The entire stump should then be carefully mounded over to the top buds of the cion with fine earth of a texture that will retain moisture without baking. The cions should be cut when entirely dormant and held in sphagnum or sawdust in an ice-house or elsewhere to keep the buds from swelling until the stocks are starting. The young growth needs to be carefully staked until the wood has hardened, as it is soft and easily broken. See *Grafting*.

Planting.

The hickories are transplanted with such difficulty that the utmost care in preparing the soil for them is required. This should be rich, deep and thoroughly drained. Planting may be done either in autumn or early spring. Pruning should be restricted to the removal of bruised or injured roots. Heavy mulch should be applied and maintained until trees are thoroughly established. After that little attention is required.

Production and use.

The fairly abundant supply of shagbarks and shellbarks in our markets is derived entirely from seedling trees. By far the larger part of this is from second-growth trees in fence-rows or the open fields where the conditions are more favorable to nut-production than in the forests. In southern New England, New York, New Jersey, Pennsylvania, Ohio and Indiana, the shagbark product is a highly prized supplemental crop on many farms. In some sections, as in southeastern Pennsylvania, the nuts are cracked by the women and children, the shelled meats being marketed in considerable quantities at satisfactory prices, many consumers preferring them to any other nut.

Varieties.

As the attention of amateurs has been concentrated on the subject in recent years, many wild trees yielding choice nuts have been located and preserved. A considerable number of these have received varietal names, but only a few have actually been propagated in such way that trees are obtainable at nurseries even in small numbers.

The qualities that should be considered in shagbarks and shellbarks from the commercial viewpoint are: (1) cracking quality, including easy release of the kernel; (2) thinness of shell; (3) size of nut; (4) plumpness and flavor of kernel; (5) productiveness.

The following sorts are worthy of consideration by those who are interested in testing representative sorts. Not all of them are yet to be had from nurseries.

Shagbarks.

Curtis.—Connecticut. A smooth nut of medium size, slightly compressed; kernel plump, light in color and of good quality; shell thin; cracking quality good.

Dover.—Pennsylvania. A medium-sized angular nut, rather broad at the base, but having a long and sharp basal point; shell moderately thin; cracking quality good; quality good.

Eliot.—Connecticut. Of medium size, compressed, angular, ovate, with prominent tip; kernel plump; flavor mild and pleasant; shell thin; cracking quality good.

Hales (*Hales Papershell*).—New Jersey. Large, quadrangular, slightly compressed, with a peculiar wavy surface; kernel rather deeply corrugated, but plump and of good quality, retaining its sweetness for two years or more; shell thin and of fair cracking quality. The Hales nut is the first-named variety of hickory, having been described and illustrated by A. S. Fuller in "The Rural New Yorker" in 1870. It is probably the only sort now obtainable at the nurseries. The original tree bears a fair crop annually, and numerous younger trees grafted from it are now in bearing.

Jackson.—Ohio. A compressed oval nut of large size; kernel large, plump, and of excellent quality; shell thin; cracking quality medium. Fig. 1836.

Kentucky.—Northern Kentucky. A nut of medium size, with quite angular and somewhat lumpy surface, short, sharp apex and flattened base, having a very short tip: shell moderately thin, kernel very plump, rich and sweet. Fig. 1837.

Kirtland.—Quadrangular, above medium size, slightly ridged and having a rather lumpy surface; shell thin, with excellent cracking quality; kernel plump, rich and of good flavor. Fig. 1837.

Leaming.—Missouri. A large nut of fine flavor and excellent cracking quality; the kernel coming out in unbroken halves.

Meriden.—Connecticut. Large, oblong, compressed; kernel large and of good quality; shell rather thick but cracks well. Fig. 1836.

Milford.—Massachusetts. A compressed ovate nut, medium to large in size, with large, plump kernel of excellent quality; cracks well; one of the best nuts yet brought to notice. Fig. 1836.

Rice.—Ohio. Angular, ovate, medium to large in size; kernel plump, bright and of fine quality; shell thin and of good cracking quality; tree regularly productive.

Swain.—Indiana. A rather long nut of medium size, with sharp apex and irregularly pointed base; surface rough; shell thin; cracking quality fair; kernel plump and sweet. Fig. 1837.

Vest.—Virginia. Of medium size, distinctly quadrangular with very lumpy surface; shell very thin and papery; kernel deeply corrugated but plump and of good quality.

Woodbourne.—Pennsylvania. Long, compressed ovate, large and smooth; kernel tender and of very high quality; shell rather thick but cracks well.

Shellbarks.

Lefevre.—Pennsylvania. Large, quadrangular, slightly ridged; shell thin, cracking fairly well; kernel very large, plump, rich and sweet.

Rieke.—Illinois. Above medium size, elongated, with a long, sharp apex and flattened base; shell moderately thick, cracking quality very good; kernel fairly plump and sweet. Fig. 1837.

Weiker.—Pennsylvania. Large, elongated, with moderately thick shell, cracking easily; kernel plump, rich and of good flavor. Fig. 1837.

Pignut.

Of the somewhat numerous sweet-flavored forms found in this species, the following one at least has been deemed worthy of perpetuation because of its delicate flavor, thin shell, and excellent cracking quality.

Brackett.—Iowa. Roundish compressed, smooth and of grayish color, medium to large in size; kernel plump, sweet and of delicate flavor; shell very thin, and easily freed from the kernel.

WM. A. TAYLOR.

HICÒRIA: *Carya.*

HIDÁLGOA ("after the Mexican Hidalgo"). Syn., *Chìldsia. Compósitæ.* A tender herbaceous vine, allied to Dahlia, with scarlet flowers about 2½ inches across, introduced in 1899 by John Lewis Childs, under the name of *Childsia Wercklei*, or "treasure vine."

Hidalgoa is closely allied to Dahlia and Coreopsis, but differs from both in the large, fertile achene of the rays and in the sterile disk-fls., the styles of which are entire or very shortly 2-lobed.—Only 2 species were hitherto recognized, both from Cent. Amer. From these *H. Wercklei* differs in its more compound lvs. and much larger heads. Suitable for cool, shady verandas but cannot be grown north of Washington out-of-doors; quite hardy in S. Calif.

Wércklei, Hook. (*Chìldsia Wércklei*, J. L. Childs). CLIMBING DAHLIA. Tall, woody at base, much branched, climbing by petioles: lvs. opposite, pinnately ternatisect, 1½–2½ in. long, 2 in. wide, the teeth tipped reddish brown; petiole 1½–2 in. long, coiled at base: peduncle axillary, as long as the lvs., 1-fld.; rays about 10, "dazzling orange-scarlet." Costa Rica. B.M. 7684. J. L. Childs' Cat. Rare Flowers, etc., 1899, p. 1, with colored plate. A.G. 20:570.

WILHELM MILLER.
N. TAYLOR.†

HIERÀCIUM (Greek, *a hawk;* it is said the ancients thought that hawks sharpened their eyesight by using the sap of these plants). *Compósitæ* (*Cichoriàceæ*). HAWK-WEEDS. Hardy herbaceous perennials, some of which are bad weeds in the eastern states.

Leaves often toothed, but never deeply lobed: heads usually small, loosely paniculate or cymose, rarely solitary; receptacle flat, usually quite naked; rays truncate, 5-toothed at the apex; anthers sagittate at the base; style-branches slender: seeds angular.—Over 400 species mostly native to Eu. and S. Amer. The genus passes into Crepis, from which it is distinguished by having stiff, usually brownish, rarely white pappus, and oblong or columnar seeds.

The cultivated species bear in summer and autumn a succession of small yellow or orange-colored flowers. There is one white-flowered species, *H. nivale.* They are often worth growing in rockeries and waste places, but care should be taken to prevent them from crowding out more desirable plants. In some parts of the East *H. aurantiacum* has become one of the worst weeds ever introduced into America. It is magnificently colored, and makes very attractive patches. *H. villosum* is the most desirable species. Hawkweeds will grow in almost any soil or aspect. They are propagated chiefly by dividing the stolons, or by seeds, and if left to themselves will soon form a dense mat of herbage over the poorest of soils. The Old World species are much confused.

A. *Flowering st. leafless or with 1–5 lvs.: lvs. mostly in a rosette at base of st.*

B. *Scapes unbranched above, bearing but a single head.*

Pilosélla, Linn. MOUSE-EAR HAWKWEED. St. slender, 4–12 in. high, stoloniferous, densely hairy throughout: lvs. entire, oblong or spatulate, narrowed into a petiole: fls. 1 in. broad, pale yellow, sometimes striped or tinged with red or purple.—Commonly flowers the whole season. Intro. from Eu. and common in dooryards and fields; often as a troublesome weed. Ont. to Pa. and Mich.

BB. *Scapes branched above, bearing several to many heads.*

C. *Basal lvs. coarsely toothed.*

vulgàtum, Fries (*H. umbròsum,* Jord.). St. 1–3 ft. high, slightly glaucous: basal lvs. 2–5 in. long, oblong to lanceolate, acute at both ends, petioled; petioles usually pubescent: fl.-stalks straight, sticky. July–Sept. Intro. from Eu. and Asia. Lab. to N. J.

CC. *Basal lvs. entire or very finely toothed.*

D. *Lvs. mostly obovate to ovate, purple-veined.*

venòsum, Linn. RATTLESNAKE WEED. St. 1–3 ft. high, slender, smooth or nearly so: lvs. 1–4 in. long, obovate to spatulate, subsessile: fls. ½–¾in. wide, bright yellow. Aug., Sept. Dry woods, Maine to Ga. and west to Manitoba and Neb.—A common plant in woods and, as an escape, a very troublesome weed. Advertised by one dealer in native plants.

DD. *Lvs. mostly spatulate to oblong, green-veined.*

aurantìacum, Linn. ORANGE HAWKWEED. DEVIL'S-BIT. St. 6 in. to 2 ft. high, slender, somewhat hairy: heads ½–1 in. across, short-stalked, orange to orange-red. June–Oct. Naturalized from Eu. by roadsides and in fields, Ont. to Pa.—A bad weed if allowed to spread. It is worthy of being established in high and dry parts of a rockery, where few other plants can grow.

præáltum, Vill. (*H. stolonìferum,* Bess.). Plants usually spreading very rapidly by stolons: st. 2–3 ft. high, slender, glaucous, hairy at base: basal lvs. entire: heads ½in. across, in an open cyme, bright yellow. June–Sept.—Naturalized from Eu. along roadsides in N. Y.; sometimes troublesome in cult. land.

AA. *Flowering st. leafy, at least below.*

B. *St. branching from the base.*

ramòsum, Waldst. & Kit. Lvs. ovate to lanceolate, narrowed at the base, toothed, hairy on margin and beneath; lower lvs. petioled, upper ones subsessile. July–Sept. Eu.

nivàle, Froel. WHITE HAWKWEED. Differs from *H. ramosum* chiefly in having white fls. and glaucous, somewhat leathery lvs., which are not hairy on the margin. A white hawkweed is advertised and, according to some, this is the only white-fld. species in the genus. Tyrolese Alps.

BB. *St. unbranched below.*

C. *Whole plant silky-villose.*

villòsum, Jacq. SHAGGY HAWKWEED. St. 1–2 ft. high, often 4 ft. under cult.: basal lvs. oblong-lanceolate to lanceolate, narrowed at the base, finely toothed; st.-lvs. sessile, the upper half clasping: fls. 1½–2 in. across, bright golden. June–Aug. Eu. Gn. 46:542. G.M. 44:596.—The silvery foliage and showy fls. of this species make it more desirable for the garden than any other hieracium now in cult. It is easily kept from spreading.

CC. *Plant smooth or slightly pubescent.*

canadénse, Michx. St. 1–5 ft. high, slender: lvs. ovate-oblong to lanceolate, acute, serrate or deeply incised, sessile, the upper with clasping base: fls. 1 in. across, the outer involucral bracts spreading. June–Aug. Dry woods, Nova Scotia to Pa., west to Brit. Col. and Ore.

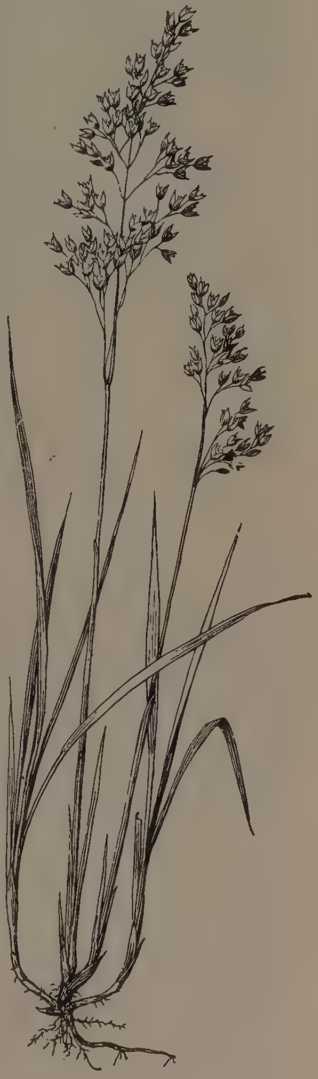
Gronòvii, Linn. St. 1–3 ft. high, stiff: lvs. hairy, the upper oval or oblong, broadly sessile, the lower obovate to spatulate, narrowed into a short petiole: fls. ½–¾in. wide. Sandy soils. Canada to Fla., west to Mo. and La.

H. alpìnum, Linn. Lvs. oblong or lanceolate, slightly toothed: fl.-sts. about 6 in. high, bearing 1–3 small, narrow lvs. and a single rather large head of bright yellow fls. Mountains of N. Eu. and Asia and the higher ranges of Cent. and S. Eu.—*H. Bórnmuelleri,* Freyn. Resembling H. villosum but lvs. thicker and more woolly, and fl.-heads larger and brighter yellow. Asia Minor.—*H. marginàtum,* Froel. A glaucous erect perennial, the leafy branches widely spreading: lvs. linear-lanceolate, st.-clasping at the base, the margins toothed and the under side reticulated: peduncles quite naked. Habitat(?). Little known in U. S.

S W. FLETCHER.
N. TAYLOR.†

HIERÓCHLOË (Greek, *hieros,* holy, and *chloe,* grass). *Gramíneæ.* Fragrant perennial grasses with flat blades and terminal panicles; only rarely planted. Spikelets with 1 terminal perfect and 2 lateral staminate florets, usually shining brown.—Species about 13, temperate and arctic regions of both hemispheres. This genus contains the fragrant vanilla-grass, the sterile shoots of which are woven by the North American Indians into small mats, baskets and boxes. These retain their fragrance for years. The seed seems to be nowhere obtainable, and only one American dealer advertises plants of it. The odor is like that of the common perennial sweet vernal grass, *Anthoxanthum odoratum,* but is more powerful. Hierochloë is closely allied to Anthoxanthum, but is distinguished by the staminate lateral florets and rather loose panicles, Anthoxanthum having sterile lateral florets and contracted panicles.

odoràta, Wahl. (*H. boreàlis,* Roem. & Schult. *Savastàna odoràta,* Scribn.). VANILLA-GRASS. HOLY-GRASS. SENECA-GRASS. SWEET-SCENTED GRASS. Fig. 1838. Rather slender, smooth, 1–2 ft. high: lvs. short: panicle brownish, spreading, 2–4 in. long. June, July. Eu., N. Amer. B. B. 1:132. Dept. Agric., Div. Agrost. 20:56. A. S. HITCHCOCK.



1838. Hierochloe odorata.

HIGGÍNSIA: *Hoffmannia.*

HILLEBRÁNDIA, (Wm. Hillebrand, author of a flora of Hawaii). *Begoniàceæ.* One of the 4 genera of the family, represented by a single Hawaiian species, *H. sandwicénsis,* Oliver. It is a begonia-like succulent herb with alternate long-petioled obliquely cordate 5- to 9-lobed lvs. and bright pink or rose-colored showy fls. in a peduncled corymb: from Begonia it differs in having the ovary free in its upper third, and bearing petaloid organs in the female fls.: petals 5 in both male and female fls.; stamens many; styles 5, fleshy: caps. globose, opening at apex, not winged. The plant grows 2–5 ft. high, from a tuberous rhizome, sparsely hairy or glabrate. It inhabits deep ravines or near waterfalls in different islands of the Hawaiian group. B.M. 6953. G.C. III. 44: suppl. Dec. 12.—Requires the treatment of shrubby or branching begonias, as in all regards but its technical botanical characters it is a begonia.

L. H. B.

HÍLLIA (Sir John Hill, 1716–1775, British botanist). *Rubiàceæ.* Shrubs of Trop. Amer., sometimes epiphytic, 2 of which are rarely grown as greenhouse or warmhouse evergreen subjects. Smooth, branches often rooting: lvs. opposite, simple, more or less fleshy: fls. large and rather showy, terminal and solitary, white and fragrant; corolla salverform, the tube long; stamens 4–7, inserted at the throat of the corolla: fr. a follicle.—Species about 10, W. Indies to S. Amer. **H. tetrándra,** Swartz. Plant 3–4 ft., the root bearing tubers: lvs. obovate to lanceolate, cuneate at base and rounded at top: lobes of corolla 4, roundish-obovate, not more than one-third length of tube. Mountains of Jamaica, Cuba; June in cult. B.M. 7355. *H. longiflòra,* Swartz, has elliptical pointed lvs., and 6–7 lanceolate bluntish reflexed corolla-lobes. W. Indies; apparently not now in the trade.

L. H. B.

HIMALAYA BERRY. The Himalaya berry is one of the evergreen blackberries of Asiatic origin. It is reported to have been introduced by Luther Burbank in the early nineties, the seed being received by him from an English traveler who secured it from the Himalaya Mountains. The vine is heavily thorned and a vigorous grower, making from 20 to 40 or 50 feet in a season and continues to grow until cold weather. It is of a trailing habit of growth, like the dewberry. The fruit begins to ripen in midsummer and gradually matures during a long period. As fruited in the Middle West, the berries are medium or below medium in size, decidedly tart unless dead ripe and with a more tender core than is usually found in the blackberry. The quality of the fruit is fair though not delicate in flavor. The fruit is of firm texture and on the Pacific coast it is reported as being a good shipper.

The Himalaya berry, like all of the evergreen blackberries, does not properly ripen its wood for winter and is not sufficiently hardy to be adapted for planting in the Upper Mississippi Valley and the other sections in which the winters are severe. Where covered with a heavy blanket of snow, the vines come through the winter in fair condition but in open winters they are completely killed back.

The Himalaya berry has been widely planted in the last three or four years, but it has not as yet established itself as a commercial berry in competition with several of the best standard varieties of blackberries with which it would be compared. See *Rubus.*

A. T. Erwin.

HIMANTOGLÓSSUM: *Orchis.*

HIMANTOPHÝLLUM: *Imantophyllum=Clivia.*

HIPPEÁSTRUM (*knight* or *horse* and *star,* from some fancied resemblance in *H. equestre,* perhaps of the equitant leaves and the star-shaped corolla-opening). *Amaryllidàceæ.* Includes *Habránthus.* Showy bulbous plants, blooming in late winter to early summer; handled under glass in frosty climates. Some of them are frequently grown as spring- or summer-blooming house-plants.

Bulb tunicate: scape hollow: lvs. linear or strap-shaped: fls. large and showy, usually two to several being borne on a stout, leafless scape; perianth-tube evident, often long, dilated in the throat; segms. erect-spreading, nearly or quite equal; filaments (6) distinct, often with small scales between; throat of perianth often closed or provided with scales or a corona: fr. a loculicidally 3-valved caps.; seeds black, usually flattened or compressed.—From 60 to 70 Trop. American bulbous plants, much cult. and now much hybridized. Closely allied genera are Amaryllis (African), Crinum, Sprekelia, Brunsvigia, Zephyranthes, Lycoris, Sternbergia, Vallota. The genus divides itself into the narrow-lvd. (lvs. linear) and broad-lvd. sections. All the common garden sorts belong to the latter section. The species chiefly known in cult., or which have been parents of hybrid races, are contrasted in this account, although the kinds commonly seen are hybrids or derivatives. In some species the fls. precede the lvs.

The hippeastrums are usually known in gardens under the general name of amaryllis; and their culture is given in full under that name. Many of them are noble garden plants, but the high price of the bulbs prevents them from becoming popular. Most of the species were first described in the genus Amaryllis, but that genus differs in its solid scape and absence of scales between the filaments. Gardeners sometimes secure blooming plants in two years from seeds, by keeping the plants growing nearly continuously. The seeds are sown in flats and pricked off into small pots at the two-leaf stage. By the close of summer, they are shifted into 4- or 5-inch pots and grown through the winter. They go into about 6-inch pots when one year old, where they grow till the second winter, when they are then partially rested; in late winter, they begin active growth again, and can be brought into flower in spring.

Very many of the names in trade catalogues are of horticultural forms; and many of them cannot be referred positively to any of the original species. For the Belladonna lily, see *Amaryllis;* for Atamasco lily, see *Zephyranthes;* for Josephine lily, see *Brunsvigia.* For *Amaryllis aurea,* see *Lycoris;* for *A. candida,* see *Zephyranthes;* for *A. formossissima,* see *Sprekelia;* for *A. gigantea,* see *Brunsvigia;* for *A. longifolia,* see *Crinum;* for *A. lutea,* see *Sternbergia;* for *A. Nerine,* see *Nerine;* for *A. orientalis,* see *Brunsvigia* (*B. gigantea*); for *A. ornata,* see *Crinum;* for *A. speciosa* or *purpurea,* see *Vallota.* Following are Latin-form trade names, probably of hybrids: *atrosanguineum, cardinalis, crocea, delicata, formosa, Lindenii, macrantha, refulgens, rubis* (hybrid), *rubra striata, Williamsii.* Other trade names may be expected in the lists of dealers.

A. *Perianth-tube 4–5 in. long, very slender.*

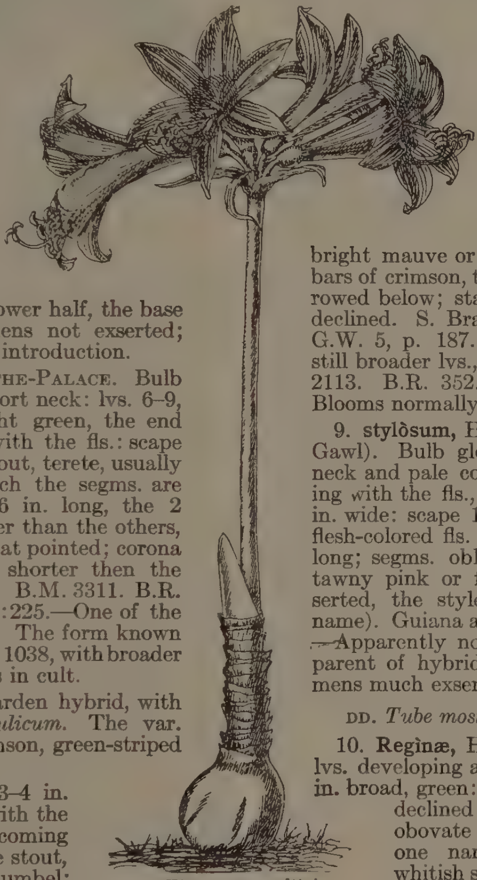
1. **solandriflòrum,** Herb. Bulb ovoid, 3–4 in. diam., with a short neck: lvs. appearing with the fls., 1–2 ft. long, 1–2 in. wide, blunt: scape somewhat flattened, 2–3 ft. tall, bearing 2–4 declined greenish white fls.; perianth-tube cylindrical, nearly as long as the obovate sometimes purple-ribbed segms.; stamens not exserted. S. Amer. B.M. 2573; 3771. L.B.C. 12:1200. I.H. 35:58. —Little known in gardens, but the parent of hybrids.

AA. *Perianth-tube short (usually not more than 1 in. long).*

B. *Throat constricted or closed by a neck or collar.*

C. *Stigma capitate.*

2. **pardìnum,** Dombr. Bulb globular, 2–3 in. diam., with a short neck: lvs. 5–7, appearing with the fls. but not fully developed until after the fls. are gone, becoming 2 ft. long and 2 in. broad, narrowed to the base: scape nearly terete, 1½ ft. tall, glaucous, usually bearing 2 spotted fls.; perianth-segms. 4–5 in. long, oblong but much narrowed at the base, acute, greenish yellow and much spotted with red, not striped, the lowest inner segm. narrowest; stamens declined, shorter than the perianth. Peru. B.M. 5645. G.W. 12, p. 654.—A handsome species, with fls. 6–7 in. across, offered in the trade, and also a parent in the modern spotted hybrids.



1839. Hippeastrum vittatum. (×⅙)

CC. *Stigma 3-parted.*

3. **Fórgetii,** Worsley. Differs from *H. pardinum* in the fls. being only partially striped, unspotted, and with narrower segms.: pedicels somewhat longer (about 3 in.); perianth dull crimson (color of *H. rutilum*), the segms. keeled in the lower half, the base green, about 6 in. across; stamens not exserted; stigma 3-lobed. Peru; a recent introduction.

4. **aùlicum,** Herb. Lily-of-the-Palace. Bulb ovoid, 3–4 in. diam., with a short neck: lvs. 6–9, 1–2 ft. long, 2 in. broad, bright green, the end blunt or nearly so, appearing with the fls.: scape scarcely longer than the lvs., stout, terete, usually bearing 2 large red fls., of which the segms. are green at the base; segms. 5–6 in. long, the 2 upper inner ones much broader than the others, all of them obovate and somewhat pointed; corona in the throat green; stamens shorter then the perianth; filaments red. Brazil. B.M. 3311. B.R. 444. Gt. 45, p. 417. Gn.M. 2:225.—One of the best, and common in the trade. The form known as var. **platypétalum,** Lindl., B.R. 1038, with broader petals and more robust habit, is in cult.

5. **Áckermanni,** Hort., is a garden hybrid, with large crimson fls., near *H. aulicum.* The var. **pulchérrimum,** Hort., with crimson, green-striped fls., is best known.

6. **psittacìnum,** Herb. Bulb 3–4 in. diam., with a long neck: lvs. with the fls., 6–8, lightly glaucous, becoming nearly or quite 2 ft. long: scape stout, 2–3 ft. tall, bearing a 2–4-fld. umbel; perianth-segms. 4–5 in. long, oblong and acute, undulate, the edge crimson, the main part green but crimson-striped; stamens much shorter than the perianth. S. Brazil. B.R. 199. L.B.C. 13:1204.—Apparently little known in cult., but it has been a parent in hybridizations.

BB. *Throat not constricted.*

C. *Stigma capitate or only obscurely lobed.*

D. *Tube of perianth ½–1 in. long.*

7. **equéstre,** Herb. (*Amarýllis equéstris,* Ait.). Barbados Lily. Bulb globular, 2 in. diam., producing offsets freely, with brown scales and a short neck: lvs. 6–8, developing fully after the fls., 12–20 in. long and becoming about 2 in. wide, narrowed to the point: scape 1–2 ft., terete, glaucous; fls. 2–4, 4–5 in. across, the green tube 1 in. long, the segms. obovate-pointed, bright red with green at the base, the 3 inner ones narrower than the outer; stamens shorter than the perianth. Mex. to Chile and Brazil. B.M. 305. G.W. 9, p. 368.—An old garden species, one of the best for winter and spring blooming. There are several garden forms and hybrids, with larger and better fls. Var. **spléndens,** Truff., R. H. 1895:578 (var. *Wálteri,* Wittm., Gt. 44, 1418), is larger in all its parts, fls. red, and the pedicels are longer. Var. **fúlgidum,** Hort. (not *H. fúlgidum,* Herb.), has brilliant orange segms. margined with white. Var. **ignéscens,** Hort., is deep clear scarlet, with white throat and white bars on the segms. Var. **màjor,** Hort., has very large, bright orange fls., with a green central star. B.R. 234. *H. Roézlii,* Regel, *H. pyrróchroum,* Lem., I.H. 11:420, and *H. spathàceum,* Sims, B.M. 2315, are regarded by Baker as forms of this species. There are double-fld. forms.

8. **reticulàtum,** Herb. Bulb nearly globular, with a short neck: lvs. appearing with the fls., rather short and broad for the genus, being oblanceolate, 1 ft. long and 2 in. broad, thin, and bright green: scape about 1 ft. tall, nearly terete, bearing 3–6 tesselated or checkered fls. 4–5 in. across; fls. bright mauve or purple-red, with cross lines and bars of crimson, the segms. obovate and much narrowed below; stamens shorter than the perianth, declined. S. Brazil. B.M. 657. R.H. 1912:448. G.W. 5, p. 187. Var. **striatifòlium,** Baker, has still broader lvs., with a white keel or stripe. B.M. 2113. B.R. 352. G.C. III. 4:477.—Handsome. Blooms normally in late summer.

9. **stylòsum,** Herb. (*Amarýllis maranénsis,* Ker-Gawl). Bulb globular, 3 in. diam., with a short neck and pale coverings: lvs. 4–6, mostly appearing with the fls., bright green, becoming nearly 2 in. wide: scape 1–2 ft., bearing 3–8 light red or flesh-colored fls. 4 in. across; perianth-tube ½in. long; segms. oblong-acute, less than 1 in. wide, tawny pink or flesh-red; stamens somewhat exserted, the style much so (whence the specific name). Guiana and Brazil. B.M. 2278. B.R. 719. —Apparently not much cult., but it has been a parent of hybrids. Var. **nùdum,** Worsley. Stamens much exserted and spreading.

DD. *Tube mostly very short (or scarcely any).*

10. **Regìnæ,** Herb. Bulb globular, 3 in. diam.: lvs. developing after the fls., 2 ft. long and 1½–2 in. broad, green: scape 10–20 in., bearing 2–4 red declined fls.; perianth-segms. 4–5 in. long, obovate and acute, the lowest innermost one narrower, all bright red, a large whitish star in the throat; tube sometimes nearly or quite 1 in. long; stamens shorter than the perianth. Mex. to Peru and Brazil. B.M. 453.—An old garden plant, still much cult. There are double-fld. forms: *Amaryllis Alberti,* Lem., I.H. 13:498, Baker considers to be one of these. *H. Gravìnæ,* Melaz., is a hybrid resembling this species (*Amaryllis Graveana?*). G.W 5, p. 187. *H. Spectábile,* Hort., is a hybrid near *H. Reginae.* L.B.C. 159.

11. **Lèopoldii,** Dombr. Bulb globular, 2–3 in. diam., with short neck: lvs. with the fls. or nearly so, often 2 ft. long: scape stout, 1½–2 ft., nearly terete, bearing about 2 large, very regular and parti-colored fls., measuring 6–7 in. across; perianth-tube without any corona or constriction at the throat; segms. obovate, 2 in. broad, the lower half dull crimson, the tips greenish white, the intermediate part bright red, with a forked white mark at the base of each, and a green-white throat: stamens declined, mostly exceeding the perianth, the filaments white; style exserted. Peru. G.C. 1870:733. G.Z. 14:160.

12. **pròcerum,** Lem. (*Amarýllis Ràyneri,* Hook. f.). Bulb ovoid, with a neck 10–12 in. long, on the apex of which—as on a trunk—the drooping, curling, buff-edged lvs. are borne (the lvs. 16–20 in. long): scape 12–18 in. high, 2-edged, green, bearing 2–3 horizontal pale lilac fls. 4–5 in. across; segms. oblanceolate, acute, not 1 in. broad; throat without a star; stamens much shorter than the perianth; stigma capitate. Brazil. I.H. 11:408. F.S. 20:2077, 2078. B.M. 5883. Gn. 45:350; 76, p. 93. G.C. III. 52: suppl. July 27. A.G. 22:713.—One of the most distinct of the genus. In the American trade. Sometimes called "blue amaryllis" and "empress of Brazil." Plant out for late summer or autumn bloom, in a warm, sunny place. Keep bulb dry until late spring.

cc. *Stigma markedly 3-parted.*

13. **rùtilum,** Herb. Bulb nearly globular, 2–3 in. diam., stoloniferous, with short neck: lvs. 6–8, elongating after flowering, bright green, 1 ft. long and an inch or more wide: scape as long as the lvs., somewhat compressed, glaucous, bearing 2–4 red fls.; perianth-tube ¾in. long, green, with a minute crown in the throat; segms. oblong, acute, crimson and green, keeled; stamens shorter than the perianth, the filaments red. Brazil. B.R. 23. L.B.C. 15:1449.—In cult. chiefly known in the var. **fúlgidum,** Baker (*H. fúlgidum,* Herb.), which is in all parts larger, deep crimson, the fl.-segms. 3–5 in. long. B.R. 226. B.M. 1943 (as *Amaryllis miniata*); 2475 (as *H. subbarbatum*). Var. **crocàtum,** Baker (*Amarýllis crocàta*) is as large as var. *fulgidum,* except in its fls., which are smaller, with undulate segms., saffron-colored. B.R. 38. Var. **citrìnum,** Baker, has bright yellow fls. Var. **acuminàtum,** Roem. (*A.* and *H. pulveruléntum*). Fls. pink and segms. acute. B.R. 534; 1188. L.B.C. 5:484. B.M. 2273.

14. **vittàtum,** Herb. Figs. 1839, 1840. Bulb globular, 3 in. diam.: lvs. 6–8, usually appearing after the fls., bright green, 2 ft. long: scape often 3 ft. high, bearing 3–6 horizontal or declined striped white-edged fls. 4–5-in. across; tube about 1 in. long, with an obscure crown or crest at the throat; segms. obovate-oblong and acute, 1½ in. or less broad, the under-color whitish but overlaid with red stripes, the keel white; stamens shorter than the limb. Peru; but once thought to be S. African. B.M. 129. G.C. III. 24:119.—The commonest species-type in American gardens, now cult. in many forms. It seems to have entered freely into hybrids, and some of the forms now passing as *H. vittatum* are perhaps mongrels. The double red feathery stripes on each side of the more or less irregular-edged segms. distinguish this species from its congeners.

1840. A flower of Hippeastrum vittatum. (×⅙)

15. **Jôhnsonii,** Bury. Fig. 1841. Fls. deep dull red, each segm. with a white stripe down the keel. A very profuse bloomer, and withstands much abuse. It is the most popular single amaryllid in this country, and is particularly prized for window-gardens. It is the oldest hybrid, having been raised by one Johnson, an English watchmaker, who, in 1799, crossed *H. Reginæ* with *H. vittatum.* Distinct and one of the best. Apparently not in American trade, but it has been used in hybridizing. G.W. 12, p. 653.

H. ádvenum, Herb. Belongs to the narrow-lvd. section of the genus: lvs. linear, glaucous: fls. 2–6, about 2 in. long, yellow or red, on slender pedicels, the segms. oblong-linear and acute; stigma 3-parted. Chile. B.M. 1125. B.R. 849.—A form with pale yellow fls. is var. *pállidus,* Herb. L.B.C. 18:1760.—*H. aulíctre,* Worsley. Garden hybrid of H. aulicum and H. equestre.——*H. iguapènse,* Wagn. Bulb small, ovate: lvs. lanceolate, 6–9 in. long and 2½ in. broad: scape about 6 in. high; fls. several, nodding, white with red or lilac stripes on upper segms. S. Brazil.—*H. Mándevillei,* Worsley. Hybrid, quaint and beautifully marked.—*H. praténse,* Baker. Also linear-lvd.: fls. 2–4, bright scarlet, the very short tube with small scales in the throat, the segms. 2½ in. long; stigma capitate. Chile. B.R. 28:35.—*H. ròseum,* Baker. Lvs. narrow-linear, glaucous, 1 ft. long, with the fls.: scape 6 in. high, bearing 1 or 2 small bright red fls.; stigma 3-parted. Chile. —*H. teretifòlium,* C. H. Wright. Distinguished by nearly terete lvs.: fls. rosy pink, 2 in. long, campanulate, few in an umbel. Montevideo.

1841. Hippeastrum Johnsonii. (×¼)

L. H. B.

HIPPOCRÈPIS, (from the Greek for *horse* and *shoe,* in reference to the shape of the pod). *Leguminòsæ.* Herbs, subshrubs or rarely shrubs, suitable for culture in the alpine garden.

Leaves impari-pinnate; lfts. entire, exstipellate; petioles rarely spinescent, persistent: fls. yellow, nodding, in racemes or axillary pedunculate spikes; ovary sessile, 1–2-ovuled; style filiform: pod flattened, indehiscent valves nearly horse-shoe-shaped.—Twelve species in Medit. region, Canary Isls., and 1 as far north as S. Scotland. Of easy cult. in ordinary garden soil. Prop. by division of the root or by seeds.

comòsa, Linn. Perennial, 8–24 in. high: st. herbaceous, prostrate: lfts. 7–11, obovate, obtuse: fls. yellow, in 4–8-fld. umbels. May–July. Cent. and S. Eu.—Grows on sunny slopes and prefers lime.

L. H. B.

HIPPÓMANE (Greek, *horse-mania,* transferred from an ancient tree name). *Euphorbiàceæ.* A poisonous tropical tree, rarely cult. in European gardens. Juice milky: lvs. simple, alternate: fls. monœcious; staminate calyx 2–3-lobed, imbricate; ovules 1 in each of the 6–9 cells: fr. a drupe.—One species. Related to Sapium and Stillingia. The juice is poisonous internally and externally, though some persons seem to be immune. It was formerly supposed that even the shade of the tree was poisonous. It was used by the natives for arrow poison, and the like. Prop. by cuttings in sand with heat. The tree needs a sandy loam soil.

Mancinélla, Linn. Manchineel. Manzanillo. A much-branched tree, 20–40 ft., with thick naked twigs, terminated by the thick, smooth, broad-ovate, short-acuminate, minutely sharp-serrate, pear-like lvs. and thick spikes: fr. berry-like, about 1 in. thick. Coasts of Cent. Amer., W. Indies and adjoining S. Amer. and S. Fla. Gt. 15:510.

J. B. S. Norton.

HIPPÓPHAË (*Hippophaës,* ancient Greek name of a spiny plant, possibly derived from *hippos,* horse, and *pheos,* a spiny plant, probably *Poterium spinosum*). Also spelled *Hippophaës.* *Elæagnàceæ.* Sea Buckthorn. Ornamental woody plants grown for their silvery gray foliage and the brightly colored berries.

Deciduous shrubs or trees with spiny branches; the young growth covered with silvery scales or stellate hairs: lvs. alternate, narrow: fls. diœcious, from the axils of last year's branches in short racemes, the axis of which mostly develops into a branchlet or thorn in the pistillate plant, but is mostly deciduous in the staminate one; staminate fls. sessile, with 2 valvate sepals and usually 4 stamens with short filaments; pistillate fls. short-stalked; the 1-ovuled ovary inclosed by a receptacle bearing 2 minute sepals at its apex, style filiform with a cylindric stigma: fr. drupe-like, with a bony ovate stone.—Two species in Eu. and W. and C. Asia.

1842. Hippuris vulgaris. (×½)

The sea buckthorns are suckering shrubs or small trees with spreading usually spiny branches clothed with silvery gray narrow and rather small foliage, with insignificant yellow flowers appearing in spring before the leaves and followed in the pistillate plant by small but numerous bright orange-yellow berries persisting through the winter. The common sea buckthorn is perfectly hardy North, while the Himalayan species is tenderer and but rarely planted. The former inhabits the sandy banks of rivers and the seashore and also the steppes of central Asia. It grows well in almost any kind of soil including limestone and saline soil; in poor sandy soil it remains shrubby and spreads freely by suckers and has therefore been used successfully for the fixation of shifting-sand dunes; in better soil it grows into a small tree. It also is used sometimes for hedges in Europe. The pistillate plant is strikingly handsome in autumn when covered with its orange berries, which often are so numerous as to weigh down the branches. To insure a good setting of berries it is necessary to plant one or a few staminate plants with each group of pistillate ones; the staminate and pistillate plants may be distinguished even without flowers or fruits fairly well by their habit, the former being of more upright growth, while the pistillate ones are more spreading and twiggy. The berries are somewhat poisonous and but rarely eaten by birds. Propagation is by seeds sown at once or stratified, by cuttings of mature wood in spring, and also by root-cuttings, suckers and layers.

rhamnoìdes, Linn. Shrub or tree, occasionally to 30 ft.: branches gray, usually spiny: winter-buds golden brown: lvs. linear-lanceolate, short-petioled, obtusish, covered on both sides with silvery scales, at maturity above often glabrescent, ¾–2½ in. long: fls. appearing before the lvs., very small, yellowish: fr. subglobose or ovoid, orange-yellow, ¼–⅓in. long, ripening in Sept. Eu. through W. and Cent. Asia to the Altai, W. China and N. W. Himalayas. B.M. 8016. Gn. 49:62. G.M. 37:791. Gn.W. 21:110. J.H. III. 51:161. G.W. 15, p. 345. Var. **angustifòlia**, Loud., a form with pendulous branches and narrow lvs. Var. **procèra**, Rehd. Tree, to 50 ft.: young growth villous: lvs. oblong-lanceolate to lanceolate, with stellate hairs above, finally glabrous above. W. China.

H. salicifòlia, D. Don. Tree, to 40 ft.: lvs. lanceolate, acute, green above, white villous-tomentose beneath, 1½–4 in. long: fr. orange, ½in. long. Temp. Himalayas. Alfred Rehder.

HIPPÙRIS (*horse-tail* from the looks of the plant). *Haloragidàceæ*. Perennial aquatic herbs, one sometimes used in bog-gardening. Sts. simple: lvs. small, simple and entire, verticillate: fls. small and inconspicuous, perfect or polygamous, sessile in the axils; petals none; calyx entire; stamen 1; nearly or quite sessile, with the thread-shaped style lying between the 2 anther-lobes: fr. nut-like, 1-seeded.—Three species, very widely dispersed in temperate and frigid regions. **H. vulgàris**, Linn. (Fig. 1842), may be transferred to wet grounds and pools: to 2 ft. (or more in deep water): lvs. 6–12 in a whorl, acute, usually withered at the apex. In ponds and streams, Greenland, and Alaska to N. Y., New Mex., Calif.; also in Eu., Asia and in Patagonia.—It produces an attractive effect with the simple shoots standing above the water in ponds. L. H. B.

HOBBLEBUSH: *Viburnum lantanoides.*

HODGSÒNIA (B. H. Hodgson, British scientist). *Cucurbitàceæ*. One species, a showy tendril-climbing shrub, in its native places in India sometimes extending 100 ft.; *H. macrocárpa*, Cogn. (*H. heteróclita*, Hook. f. & Thom.), hardly to be expected in cult. Lvs. coriaceous, 6–8 in. long, deeply 3–5-lobed, the lobes entire or slightly dentate: fls. diœcious, white, tinged yellow within, the limb of the deeply 5-parted corolla bearing curling fringes 4 in. long; male fls. in long racemes, females solitary; calyx very long-tubular and slender; stamens 3, exserted; stigmas 3 and 2-fid, exserted: fr. berry-like, spherical, 4–10 in. across, red-brown and tomentose; seeds 2–3 in. long. F.S. 12:1262.—This odd and showy plant is said to require the conditions provided by a temperate greenhouse, although some report it as requiring hothouse treatment. L. H. B.

HOFFMÁNNIA (Georg Franz Hoffmann, 1760 or 1761–1826, professor of botany at Goettingen). Including *Campylóbotrys* and *Higginsia*. *Rubiàceæ*. Tropical American herbs or shrubs, with opposite or verticillate leaves and small white, yellow or red flowers, cultivated for the very showy foliage.

Branches either terete or 4-angled: lvs. simple: corolla tubular, with 4 (rarely 5) oblong or linear-obtuse lobes; stamens mostly 4; disk ring-like about the 2–3-loculed ovary or cushion-like; style filiform, the stigma 2-lobed: fr. an oblong or narrow many-seeded berry.—Species above 30, Cent. and S. Amer. The hoffmannias require warm temperature, although they may be plunged in the open in the summer. Well-grown specimens are also adapted to the decoration of window-gardens and living-rooms. Prop. by cuttings. Hoffmannias are very showy foliage plants.

1843. Hoffmannia discolor. A loose-growing sprig. (×⅓)

A. *Fl.-clusters on long stalks.*

díscolor, Hemsl. (*Campylóbotrys díscolor,* Hook.). Fig. 1843. About 6 in. high, but lopping over the side of the pot or pan and making a mat, slightly hairy, the branches purplish: lvs. short-petioled, oblong-obovate, entire, satiny green above and rich light purple to green beneath: fls. small, red, in recurving racemes, on red peduncles. Mex. B.M. 4530.—Excellent little plant.

refúlgens, Hemsl. Much like the former, but twice or more as large, the lvs. sessile and almost succulent, narrow-obovate, with many parallel veins running from the midrib to the margin, the under-surface pale red or wine-color and the upper surface dull green, with iridescent shades of purple and brown: fls. 1 in. across, pale red. Mex. B.M. 5346 (as *Higginsia refulgens*). H.F. II. 5:78.—A most beautiful plant.

AA. *Fl.-clusters crowded in the axils.*

Ghièsbreghtii, Hemsl. (*Campylóbotrys Ghièsbreghtii,* Lem.). Half-shrubby, 2–4 ft. tall, nearly glabrous: st. acutely 4-angled: lvs. usually 1 ft. or less long, oblong-lanceolate-acuminate, entire, the short winged petiole somewhat decurrent, very strongly veined, purple-red beneath and dark velvety green above: fls. yellow, with a red spot in the center. Mex. B.M. 5383 (as *Higginsia Ghiesbrechtii*). I.H. 8:279 (as Campylobotrys). G.W. 15, p. 330.—A form with handsomely mottled lvs. is var. **variegàta,** Hort. (I.H. 30:498).

regàlis, Hemsl. (*Campylóbotrys regàlis,* Lind.). Shrubby, strong-growing, glabrous, the branches obtusely 4-angled and somewhat fleshy: lvs. large, round-ovate and abruptly acuminate, entire, plicate with arched nerves, glabrous, purple-red beneath and dark rich green above: fls. yellow, sessile. Mex. B.M. 5280 (as Higginsia).

H. phœnicópoda, K. Schum. Lvs. ovate to oblong, violet-red beneath: fls. inconspicuous. Cent. Amer.

L. H. B.

HOFFMANSÉGGIA (Joh. Centurius, Count von Hoffmansegg, born 1766; wrote on plants of Portugal). *Leguminòsæ.* Thirty and more dwarf mostly glandular herbs and subshrubs from Kans. and Calif. to Patagonia, and in S. Afr., perhaps not cult.: lvs. bipinnate, with or without black glands: fls. yellow in naked racemes opposite the lvs. or terminal; petals 10 and nearly equal; stamens 10 and distinct: pod flat, oblong, sometimes falcate. The genus is allied to Cassia, from which it differs in its bipinnate rather than pinnate lvs., and to Cæsalpinia, which is distinguished by its prickles, woody stature, and other characteristics.

HOHENBÉRGIA (personal name). *Bromeliàceæ.* Interesting hothouse subjects grown in pots, closely allied to Æchmea.

Leaves forming a dense rosette, spiny-margined, often terminated with a stout spine: panicle on a tall scape, bi- or tripinnate, of short, dense, sessile or stipitate spikes; fls. sessile in the axils of large bracts, white or blue.—A Trop. American genus of about 20 species.

augústa, Mez (*Æchmèa augústa,* Baker. *Hoplophỳtum augústum,* Beer). Lvs. up to 3 ft. long and 3 in. broad, spiny, with pale scales on both sides: panicle pyramidal, much exceeding the lvs., floccose; fls. a little less than ½in. long, the petals blue. Brazil.

stellàta, Schult. (*Æchmèa glomeràta,* Hook.). Lvs. up to 3 ft. long, and 3 in. wide, marginal spines long: panicle interrupted, equaling or little exceeding the lvs.; fls. about 1 in. long, the petals blue. Trinidad and Brazil. B.M. 5668.

Legrelliàna, Baker (*Æchmèa Legrelliàna,* Mez. *Guzmània Legrelliàna,* Hort.). A strong billbergia-like plant, with 7–12 strong, entire, brown-scaly lvs. and a simple dense spike of red fls. standing 4–7 ft. high: floral bracts serrate. Uruguay.

George V. Nash.

HOHÈRIA (from the New Zeal. vernacular name *hoheri*). *Malvàceæ.* Small trees or shrubs native to New Zeal.: lvs. variable, alternate, serrate, petiolate: fls. numerous, white, in axillary fascicles; peduncles jointed at the middle; bracteoles wanting; calyx hemispherical, 5-toothed; petals oblique, notched near the apex; staminal column split at the top into numerous filaments, usually arranged in 5 bundles: fruiting carpels 5, indehiscent, furnished with a broad membranous wing at the back.—Three or 4 species; by some regarded as one variable species. *H. popúlnea,* A. Cunn. A small, handsome tree, 10–30 ft., glabrous except the young shoots, peduncles and calyxes, which are more or less pubescent: lvs. very variable, especially in young plants: fls. snow-white, produced in great profusion: carpels produced outward and upward into a membranous wing, longer than broad. G.C. III. 30:384; 52:355. Gn. 62, p. 309; 76, p. 580. Scarcely cult.

HOIBRÉNKIA: *Staphylea.*

HOLBOÈLLIA (Frederick Louis Holboell, once Superintendent of Botanical Garden, Copenhagen). *Lardizabalàceæ.* Ornamental vines grown chiefly for their handsome evergreen digitate foliage.

Twining shrubs: lvs. coriaceous, long-petioled, digitate, with 3–9 stalked entire lfts.: fls. monœcious, in few-fld. racemes; sepals 6, petal-like, obtusish, fleshy; between the sepals and the 6 free stamens 6 small nectaries sometimes called petals; the staminate fls. with rudimentary ovaries; the pistillate with small stamens and 3 distinct carpels developing into 1–3 large oblong pods with numerous black seeds.—Five species in China and Himalayas.

The holboellias are quick-growing evergreen vines very similar in foliage to *Akebia quinata* but the flowers are quite different; they are either white or the pistillate are purplish and the staminate which are borne in separate racemes whitish or greenish white; they appear with the young leaves in spring and are not showy, but the large purple pods are conspicuous. None of the species is hardy North, but the plants should be tried outdoors in the South where an evergreen quick-growing climber is desired, as they make annual shoots 10 to 12 feet long, and the foliage is distinct and beautiful. For the cool greenhouse they are too rampant and produce too few flowers. Propagation is by seeds which germinate readily; also by layers and by softwood cuttings. For further cultural notes, see *Stauntonia.*

coriàcea, Diels. Lfts. always 3, coriaceous, ovate to oblong-lanceolate or narrow-oblong, acute, rounded or broadly cuneate at the base, light green below with the veinlets not visible, 2–3½ in. long: fls. ⅓–½in. long; the staminate whitish, on pedicels about 1 in. long, the pistillate purplish on pedicels to 2 in. long. Cent. China.

latifòlia, Wall. Lfts. 3–7, ovate-oblong to elliptic-oblong, acuminate, pale green below and reticulate, 2½–3½ in. long: fls. about ½in. long, in short-peduncled racemes, on pedicels ¼–½in. long; the pistillate purple, the staminate greenish white, fragrant: fr. consisting usually of 2 oblong carpels, each about 4 in. long and 2 in. thick, rosy purple, edible. Himalayas. B.R. 32:49. J.F. 2:144. R.H. 1890:348. Gn. 8, p. 548; 14, p. 369.

H. cuneàta, Oliver=Sargentodoxa cuneata.—*H. Fárgesii,* Réaubourg. Lfts. 5–9, usually oblong-lanceolate, glaucescent below: fls. ¾in. long, purplish and greenish white. Cent. China.—*H. grandiflòra,* Réaubourg. Lfts. 5–7, usually lanceolate, reticulate and grayish green below: fls. nearly 1 in. long, waxy white. W. China.

Alfred Rehder.

HÓLCUS (Latin name for a kind of grass, from *holkós,* attractive). *Gramíneæ.* This genus, named Holcus by Linnæus, was called Sorgum by Adanson (*Sorghum,* Moench). The name Holcus was accepted by some botanists while by others the genus was united with

LV. Hollyhock.

Andropogon. It seems best, however, to restore the Linnæan name. They are important fodder grasses.

The genus differs from Andropogon in having spikelets in 3's in an open or contracted panicle. The various cult. varieties known as sorghum or sorgo, broom-corn, Jerusalem corn, milo maize or milo, durra, and so on, are considered by some botanists to have been derived from the wild species, *H. halepénsis*, Linn. (*Andropògon halepénsis*, Brot. *Sórghum halépense*, Pers.). Others maintain these cult. forms as varieties of a distinct species, *H. Sórghum*, Linn. (*Andropògon Sórghum*, Brot. *Sórghum vulgàre*, Pers.). The cult. forms are annuals, with tall jointed sts. bearing large terminal panicles. Depending upon their uses, they fall naturally into 3 groups: (1) Broom-corn, in which the branches of the panicle are elongated and are thus adapted to the manufacture of brooms; (2) the sugar or saccharine sorghums, having loose panicles, with drooping branches and red-brown spikelets, cult. for the sweet juice and for forage. Amber and Orange are leading forms of sugar sorghum. (3) The remaining varieties are grouped together as non-saccharine sorghums. They are grown for forage and for the seed. Gn. 4, p. 83 (as *S. bicolor*). The common forms grown in this country and offered in the trade are: Kafir corn, with sts. 4–5 ft. high, stocky growth, and dense, upright panicles; milo or milo maize, or African millet, similar but about twice as tall; durra (variously spelled doura, dhoura, and so on), including Egyptian rice corn, and Guinea corn, with compact panicles on an often recurved stalk. The wild species, *H. halepensis*, Linn., JOHNSON-GRASS, has a large open panicle of smaller spikelets. Gn. 13, p. 305. Dept. Agric., Div. Agrost. 14:12.—It is a perennial, spreading by stout rhizomes and very difficult to eradicate from cult. ground. For history of sorghums see Dept. Agric. Bur. Pl. Ind. Bull. No. 175 (1910) and Bur. Pl. Ind. Circ. No. 50 (1910). Sudan-grass and Tunis-grass are varieties of sorghum that resemble Johnson-grass in aspect but are annuals devoid of rootstocks. They have recently been intro. in the U. S. and give promise of value as forage plants in the southern states. See "Some New Grasses for the South," Yearbook U. S. Dept. Agric., 1912.

H. lanàtus=Notholcus lanatus.

A. S. HITCHCOCK.

HOLLY: *Ilex.*

HOLLYHOCK (*Althæa rosea*, which see). Figs. 1844, 1845. The hollyhock is one of the very oldest of cultivated flowers and is today an inhabitant of most gardens, and is known by its common name not only to all cultivators of plants but even to school-children. Its showy blossoms in July after the larger number of plants have ceased flowering has much helped to make it known to all, while its history, its place in poetry and folk-lore, and its associations in the past drama of the world have been forgotten or vaguely remembered. Its beauty causes its cultivation today.

The hollyhock is a native of China, botanically described as a biennial and evidently a cultivated plant in China when first brought to the attention of European cultivators, since it is said to have been "of many colors and forms." Very probably its colors in a wild state, as now often seen in mixed retrograde seedlings, were rose-pink tending to red and white. The real reds and the present deep maroon shades would naturally be obtained rather easily by selection. The yellow color is, in the opinion of some, a much later acquired one, and the least liable to come true from seed.

The doubleness of the flower has undoubtedly been an acquired character under cultivation. The hollyhock has been propagated almost entirely from selected seed for so many years that both in color and doubleness it comes true from seed which has not been cross-fertilized with other colors or forms.

The bees delight in the plentiful pollen of the hollyhock so that in a mixed group of plants the seed will be indiscriminately crossed, and naturally a few poor single-flowered plants may affect the seed from a whole group. The color of the flower is, however, much influenced by the seed-bearing parent. The pollen on the hollyhock is so plentiful that the bee soon gets a load and goes home, in many cases not having visited more than one plant. For this reason a short distance between groups, especially if separated by some barrier, very much prevents cross-fertilization. Purchased seed comes about 75 per cent true to color and possibly 40 per cent fairly double.

The hollyhock, while called in botanical history a biennial, is at least a short-lived perennial. Its heavy type of root with very short stolons or rather side crown-buds at the head of the root-system would naturally lead to its description as a biennial. It belongs, because of its root-system, to a horticultural class of plants, which, while truly perennial under proper conditions become biennial or even annual under other circumstances. Other plants having very similar root-formations are the dandelion, digitalis, aquilegia, platycodon and delphinium. These are more or less short-lived perennials since their permanency depends on the preservation of an easily destroyed crown-bud or rather the head of the root-system. Heaving of the plant by frost exposes the main root-stem below the side buds and causes the plant to die after flowering. In like manner the removal of soil from about the plants, as by rains, shortens the life by exposing the root below its natural level with the soil. The seed of the hollyhock, as well as the other genera mentioned with this root-system, germinate very quickly —five to ten days.

1844. The hollyhock.

Hollyhock seeds sown in the greenhouse or frame during March or earlier and given plenty of root-room will flower the first year from seed although somewhat later than established plants. Plants grown as above in pots are likely to show less perennial character of the root and are more liable to disease. The seed should be sown outdoors during June or July in soil with sufficient clay and surface soil-water to cause the seedlings to form a system of strong side tap-roots, rather than one or two main roots as will occur in too sandy or dry soil, or on the other hand too many fibrous surface-roots as when grown in pots or in a too-wet soil.

Plants from outdoor spring- or early summer-sown seed should be moved to their permanent positions early the following spring, care being taken to dig the plant with all the main roots, and in planting to place these roots in a natural position, i.e., pointing downward. The crown of the plant should be a little below the surface of the ground (this is important). Fall planting, with the heaving by frost, especially of tap-rooted plants, means replanting in the spring to the proper depth or the usual loss of the plant after one year's bloom.

Hollyhocks may be propagated in the spring by placing a plant in sand so as to cover the crown of the root which will cause a number of suckers to be sent up about the crown, which may be removed and rooted.

The hollyhock rust (*Puccinia malvacearum*) bothers very little in deeply dug and drained beds with plants grown outdoors and planted with the tap-roots properly placed and the crowns in the proper place in reference to the soil-surface. An appreciation of the deep-rooting, drainage-liking habit and qualifications of the plant will do more to combat this disease than any amount of bordeaux mixture. In the United States Experiment Station Record, Vol. XXXI, No. 3, note is made from an article in a French publication (Compt. Rend. Acad. Sci. 158, No. 6) which declares the hollyhock rust to have been successfully combated during a three-year trial by supplying as water to the roots a 3 per cent solution of copper sulfate.

1845. Semi-double hollyhock. (×½)

In landscape work, the hollyhock best belongs to the herbaceous perennial groupings, but it can be well used alone in groups adjoining shrubbery, or in many places in place of shrubbery. It can seldom be used to advantage in mixture with woody plants, since the hollyhock needs light on its lower basal leaves. Further, the foliage of the hollyhock neither resembles nor contrasts well with that of the larger number of shrubs, although there are exceptions, for example, hydrangeas of the arborescens type and hollyhocks form a pleasing mixture.

F. W. Barclay.

HOLLY, SEA: *Eryngium.*

HOLMSKIÒLDIA (Theodor Holmskiold, 1732–1794, Danish nobleman and scientist). *Verbenàceæ.* Shrubs, one of which is offered, suitable for growing under glass.

Leaves opposite, entire or dentate: fls. racemose or cymose; calyx membranaceous and colored; corolla cylindric and curved, the oblique limb with 5 short lobes; stamens 4, didynamous, the anthers exserted: fr. an obovoid drupe, 4-lobed, included in the enlarged calyx. Probably 3 species, African and Asian. **H. sanguínea,** Retz., is a straggling shrub 10–30 ft. high, in the subtropical Himalayan region: lvs. 3 in. long, ovate, acuminate, entire or toothed: corolla 1 in. long, brick-red to orange: drupe ⅓in. or less long, the calyx 1 in. diam. Offered abroad; an evergreen shrub.

L. H. B.

HOLODÍSCUS (Greek *holos,* entire, and *discos;* the disk is entire). Syn., *Schizonòtus, Sericothèca. Rosàceæ.* Ornamental shrubs, cultivated for the showy panicles of creamy white flowers.

Deciduous, more or less pubescent: lvs. alternate, petioled, without stipules, incisely serrate or pinnately lobed: fls. in terminal panicles, perfect; calyx cup-shaped, 5-lobed; petals 5; stamens about 20; ovaries 5, surrounded by an entire disk, developing into 5 distinct, pubescent, 1-seeded achenes. Formerly usually referred to Spiræa, but more nearly related to Exochorda.—About 14 closely related species ranging from Brit. Col. through Mex. to Colombia, and east to Idaho, Colo. and New Mex., have been distinguished; by some botanists they are reduced to 5 or even to only 2 species.

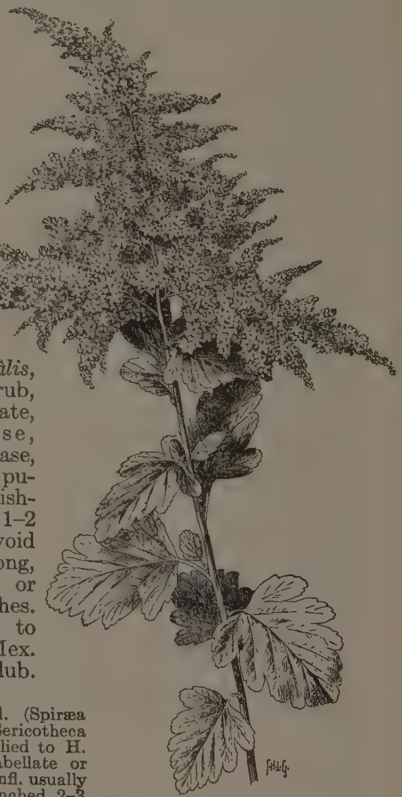
These are ornamental free-flowering shrubs with rather small dull green foliage and small, whitish flowers in ample showy panicles: fruit insignificant. *H. discolor* is a very graceful plant, with its drooping feathery panicles of creamy white flowers, and well adapted for borders of shrubberies or for single specimens on the lawn; it is hardy in favorable localities as far north as Massachusetts. They grow in almost any well-drained soil, and do best in a sunny position. Propagation is by seeds usually sown in boxes in fall and only slightly covered with soil, or by layers; sometimes also increased by greenwood cuttings under glass taken with a heel, but usually only a small percentage of them take root.

díscolor, Maxim. (*Spiræa díscolor,* Pursh. *Sericothèca díscolor,* Rydb.). Fig. 1846. Shrub, to 20 ft., with slender, arching branches: lvs. ovate or oblong, truncate or narrowed at the base, pinnately lobed, lobes dentate or nearly entire, usually glabrous above, pubescent or tomentose beneath, ½–3 in. long: fls. creamy white, small, in ample drooping panicles 3–9 in. long. July. Brit. Col. to Calif., east to Idaho and Mont. Gn. 45, p. 56; 47, p. 188; 49, p. 104; 50, p. 278; 63, p. 195; 74, p. 41; 76, p. 556. G.C. III. 25:21; 32: suppl. Oct. 11. G.W. 8, p. 302. G.F. 4:617. G. 25: 363. B.R. 1365. R.H. 1906, p. 440.—The typical form has the lvs. whitish tomentose below; var. **ariæfòlius,** Aschers. & Graebn. (*Spiræa ariæfòlia,* Sm.), which is the commonly cult. form, has the lvs. grayish green and pubescent below.

dumòsus, Heller (*H. díscolor* var. *dumòsus,* Dipp. *Spiræa dumòsa,* Nutt. *H. austràlis,* Heller). Erect shrub, 8 ft. high: lvs. obovate, acute or obtuse, cuneate at the base, coarsely toothed, pubescent above, whitish-tomentose beneath, 1–2 in. long: panicle ovoid or conic, 2–7 in. long, with ascending or spreading branches. Wyo. and Utah to New Mex. and Mex. Bull. Torrey Bot. Club. 25:338.

H. Boursièri, Rehd. (Spiræa Boursieri, Carr. Sericotheca Boursieri, Rydb.). Allied to H. dumosus, but lvs. flabellate or roundish, smaller and infl. usually simple or sparingly branched, 2–3 in. long. Calif. R.H. 1859, p. 519.

Alfred Rehder.



1846. Holodiscus discolor. (×⅓)

HÒLOTHRIX (from the Greek for *whole* and *hair;* in reference to the st. being covered with hairs). *Orchidàceæ.* A group of 50–60 species of terrestrial orchids from S. Afr. and Madagascar. Lvs. 1 or 2, sessile, ovate or orbicular-reniform, radical: scapes slender, usually hairy and without sheaths; fls. small, in slender, usually secund spikes; sepals connivent, sometimes hairy; petals smaller and longer, entire or variously divided at the apex; lip erect or spreading, adnate to the base of the column; column very short, usually auricled at the sides of the stigma: caps. ovoid or oblong. These plants require the temperature of a warm greenhouse and thrive in a mixture of peat, sphagnum and charcoal. *H. villòsa,* Lindl. Lvs. round, fleshy, hairy, borne close to the surface of the soil: infl. about 9 in. high; fls. about 30, small, yellowish green, slightly fragrant. S. Afr.

HOMALÁNTHUS (Greek *homalos,* like, and *anthos,* flower). *Euphorbiàceæ.* Tropical trees, sometimes cultivated in warmer regions or in greenhouses for the foliage.

Juice milky: lvs. simple, alternate, petioled, entire, glabrous, usually triangular-ovate: fls. apetalous, inconspicuous, in terminal racemes, the pistillate at the base; staminate calyx of 1–2 sepals, stamens 5–50: ovules 1 in each of the 2–3 cells.—Nineteen species distributed from S. E. Asia and Pacific islands to Austral. Related to Sapium and Stillingia. Some species closely resemble species of Sapium in foliage and habit. Sometimes spelled Omalanthus. The cult. and propagation are about the same as for the tree-like euphorbias.

populifòlius, Graham (*Carúmbium populifòlium,* Benth.) Queensland Poplar. Lvs. 2–4 or more in. long and as wide, slender petioled, glaucous, copper-colored when young, rarely subpeltate: racemes slender, 3–4 in. long; sepals of staminate fls. 2; stamens 5–6; stigmas without glands. Austral. B.M. 2780.

H. popúlneus, Pax=H. Leschenaultianus, Juss., of Malay region, sometimes confused with H. populifolius but separated by Pax on the glandular stigmas, may be in cult.; as also the following: *H. fatuòsus,* Vill. Lvs. peltate. Gt. 15:504.—*H. gigantèus,* Zoll. Monosepalous, stamens 10–20.—*H. polyándrus,* Cheesem. Monosepalous, stamens 40–50.

J. B. S. Norton.

HOMALOMÈNA (Greek, variously explained). Also written *Homalonema. Aràceæ.* Tender foliage plants, variegated after the fashion of the well-known dieffenbachias, and the rarer aglaonema and schismatoglottis.

Robust herbs, with a thick rhizome: st. short or none: lvs. ovate- or triangular-cordate, or lanceolate, nerves reaching the margin; petiole mostly long and sheathing: stamens distinct: fr. included within the persistent spathe; ovules anatropous, adnate to the septa.—About 80 species, natives of Trop. Asia and Amer. It is probable that the plants seldom produce fls. or fr. in cult. They are known to the trade as Curmeria, which is now regarded as a section of Homalomena, in which the spathe has a distinct tube and the lvs. are either glabrous or pilose, while in the section Euhomalomena the spathe has an indistinct tube, and the lvs. are always glabrous. For cult., see *Dieffenbachia.* Latest Monograph by Engler in Das Pflanzenreich, hft. 55. 1912. The species described below belong to the subgenus Curmeria, with 4 other species, American; the other species are Asian and of Pacific islands.

A. *Lvs. irregularly blotched.*

Wállisii, Regel (*Curmèria Wállisii,* Mast.). Fig. 1847. Lvs. glabrous throughout, the base obtuse or acute, not notched; petiole 1½ in. long; blade 5 in. long, 2–2½ in. wide. Colombia. G.C. II. 7:108. B.M. 6571 (midrib outlined in light color). I.H. 25:303. R.H. 1878, p. 193.—The blotches are pale yellowish green, becoming greenish gray. None of these pictures shows a white-bordered lf. with golden blotches, as one dealer advertises.

AA. *Lvs. with midrib bordered with white.*

picturàta, Regel (*Curmèria picturàta,* Lind. & André). Lvs. with petiole and midrib pilose; petiole 4 in. long; blade 10–12 in. long, 8 in. wide. Colombia. I.H. 20:121.—Blotched only near the midrib.

Wilhelm Miller.

HOMÈRIA (said to be from *homereo,* alluding to the *meeting* or *joining* of the filaments). *Iridàceæ.* Half-hardy bulbs that can be set out in spring, and bear orange-colored or red flowers in summer.

1847. Homalomena Wallisii.

It is an endemic Cape genus of about 6 species: st. erect from a tunicated corm, producing 1 or more peduncles above: developed lf. usually 1, linear, surpassing the st.: fls. in one or few clusters, successive and fugaceous; perianth funnelform, very deeply cut, the segms. narrow and nearly equal or sometimes the 3 inner ones narrower; stamens united by their filaments into a column: fr. a clavate caps.—Homeria is allied to Sparaxis, requires the same cult., and the bulbs are dormant from Aug. to Nov. It belongs to the Moræa tribe, in which the fls. are stalked and more than 1 to a spathe, and the style-branches placed opposite the stamens. It differs from Iris and Moræa in having style-branches furnished with terminal stigmas not overtopping the anthers. Nearer allies of garden value are Tigridia, Herbertia and Ferraria, from all of which it differs in the 2 petaloid stigmatose crests at the ends of the style-branches.

collìna, Vent. (*Moræa collìna,* Thunb.). Corm globose, ¾–1 in. diam.: lf. linear, rigid, 1½–2 ft. long, overtopping the fls.: st. bearing 1–4 clusters of fls.; perianth-limb 1¼–1½ in. long, typically bright red, as in B.M. 1033; G.C. III. 4:163; 50:476. Var. **aurantìaca,** Baker, has a slenderer habit and yellow-clawed, bright red segms. which are narrower and more acute than the type. B.M. 1612. Var. **ochroleùca,** Baker, has the habit of the type and pale yellow fls. B.M. 1103.

The other species of Homeria are as follows: *H. élegans,* Sweet. Outer segms. tawny, the others or sometimes all 6 yellow, the 3 outer with large green or yellow-brown blotch in middle.—*H. lineàta,* Sweet. Fls. copper-red, with small yellow-dotted blotch at base inside.—*H. maculàta,* Klatt. Fls. yellow, the segms. with a greenish claw and greenish blotch above the base.—*H. mineàta,* Sweet. Fls. tawny or fulvous-red throughout.—*H. pállida,* Baker. Fls. pale yellow.

L. H. B.

HOMOCÉLTIS: *Aphananthe.*

HOMÓGYNE (from *homos,* similar, and *gyne,* female, because of similarity of male and female fls.). *Compósitæ.* A small and little-known group of hardy perennials grown for their attractive white or purple heads of showy flowers.

Leaves more or less white-woolly, radical broad, cordate or sometimes sinuate-dentate, usually smaller than those in Tussilago and Petasites, to which the genus is related: scapes 1–2-headed, usually all of disk-fls.: achenes linear, 5–10-ribbed.—There are only 3 known species, all from the mountains of Cent. Eu., and they prefer moist garden borders in cult. Prop. by division in spring. Perhaps not in cult. in Amer.

alpìna, Cass. (*Tussilàgo alpìna*, Linn.). About 6 in., the st. simple: the lower lvs. cordate-reniform, those of the st. ovate-lanceolate, the radical ones withering before flowering time: fls. in solitary heads, terminating the st., all discoid, light purple. B.M. 84 (as *Tussilago alpina*).—Perhaps better treated as a partial alpine. N. Taylor.

HONCKÉNYA (named after G. A. Honckeny, 1724–1805, author of a flora of Germany). *Tiliàceæ.* Trees or shrubs covered with stellate pubescence: lvs. entire or lobed: fls. large, blue-violet, showy, in terminal racemes; calyx of 4–5 sepals; petals 4–5, glandless at the base: caps. oblong, loculicidally 4–8-valved; seeds numerous, horizontal, compressed.—Two or 3 species in Trop. W. Afr. *H. ficifòlia*, Willd., is offered abroad. Shrub, with purplish branches: lvs. cordate, roundish or oblong, more or less deeply 3–7-lobed: fls. numerous, in terminal racemose cymes; sepals 3–5, oblong; petals roundish, stalked; ovary 4–8-celled, with numerous ovules in each cell: caps. 1–2 in. long; valves covered with numerous, spreading ciliated bristles, each terminated by a small, white deciduous point. Guinea. B.M 7836.—A handsome-fld. shrub. Prop. by cuttings of young wood inserted in sand under glass with bottom heat. Thrives in a mixture of loam and peat. L. H. B.

HONESTY: *Lunaria annua.*

HONEY LOCUST: *Gleditsia triacanthos.* **Honeysuckle:** *Lonicera.* **Honeywort:** *Cerinthe.*

HOÒDIA (from a personal name). *Asclepiadàceæ.* Stout low perennial succulents of Trop. and S. Afr., sometimes seen in choice amateur collections; species about 10 or 12: allied to Huernia and Stapelia: plant usually branched, with spine-tipped tubercles, cactus-like: fls. large and showy, solitary or in small clusters, springing from the grooves toward the top of the st., yellowish, purplish or tawny; limb of corolla entire or slightly 5-lobed, the lobes subulate-pointed; corona double, arising from the staminal column, each part of 5 lobes. Require greenhouse treatment, probably similar to related genera. L. H. B.

HOÒKERA: *Brodiæa.*

HOP: *Humulus.* **Hop Hornbeam:** *Ostrya.* **Hop, Wild:** *Bryonia dioica.*

HOPLOPHỲTUM. Several bromeliads have been described under this name, but the species are now referred to *Æchmea. Halophytum* of one trade catalogue is apparently an error for *Hoplophytum.*

HÓRDEUM (an ancient Latin name for barley). *Gramíneæ.* Annual or perennial grasses with terminal bristly spikes.

Spikelets 1-fld., 3 together at each joint of the rachis, the middle one sessile and perfect, the lateral usually pedicelled, often reduced to awns: the rachis breaking up at maturity into single joints with the cluster of spikelets attached.—Species about 16, temperate regions of both hemispheres. Elymus, some species of which resemble Hordeum, differs in having 2 developed, several-fld. spikelets at each node. Hordeum includes the cult. barley (*H. vulgare*, Linn.) and several troublesome weeds. Among the latter may be mentioned, *H. murinum*, Linn., called Wild Barley, Barley-Grass and Foxtail on the Pacific slope; *H. nodosum*, Linn., common throughout the U. S., and *H. jubatum*, Linn. Squirrel-tail Grass, called Fox-tail in Wyo. and Tickle-Grass in Nev. The first two are annual. The last, a perennial, is also cult. for ornament.

jubàtum, Linn. Squirrel-tail Grass. Wild Barley. Erect, simple, usually smooth and glabrous, 10 in. to 2 ft. high: lvs. 1–5 in. long: only the central spikelet in each cluster perfect; awns of empty glumes 1–2½ in. long, spreading. In dry soil, N. U. S. and Canada. B.B. 1:229. Dept. Agric., Div. Agrost. 17:307.—Sometimes cult. for ornament on account of the feathery heads. A. S. Hitchcock.

HOREHOUND: *Marrubium.*

HORMÌNUM (old Greek name for sage). *Labiàtæ.* One herbaceous perennial, **H. pyrenàicum,** Linn., adapted to borders and rock-gardens: sts. simple and nearly leafless: lvs. mostly radical, ovate, toothed or crenate, the floral lvs. reduced to bracts: fls. medium size, purple-violet, nodding, in secund verticils or whorls; calyx campanulate, 2-lipped, about 13-nerved; corolla-tube exserted, the limb somewhat 2-lipped, the upper lip truncate-emarginate, the lower or anterior 3-parted; stamens 4, didynamous; style 2-lobed: nutlets ovoid. The plant grows 8–12 in. high; Pyrenees to the Tyrol; it makes a tuft of foliage; blooms in midsummer; hardy in England. Vars. *álbum* and *grandiflòrum purpùreum* are offered. Other plants sometimes referred to Horminum are properly salvias. L. H. B.

HORNBEAM: *Carpinus.*

HORNED POPPY: *Glaucium.*

HORSE, in combination with other names of plants, usually signifies something large and coarse, not necessarily eaten by horses.

HORSE BALM: *Collinsonia.* **Horse Bean:** *Vicia Faba.* **Horse-Chestnut:** *Æsculus.* **Horse Mint:** *Monarda.* **Horse-radish Tree:** *Moringa pterygosperma.* **Horse Sugar:** *Symplocos tinctoria.* **Horse-tail:** *Equisetum.* **Horseweed:** *Collinsonia.*

HORSE-RADISH (Fig. 1848), the well-known condiment used so much with roast beef and oysters, is a member of the natural family Cruciferæ, to which belong cabbage, turnip, wallflower, stock, charlock, mustard, and many other vegetables, flowers and weeds. It comes to us from Great Britain, where it is thought to have been naturalized from some more eastern European country. It is often found growing wild in moist locations, such as the margins of streams, in cool woods and damp meadows, and, in some places, notably in the state of New York, is troublesome as a weed.

1848. Good root of horse-radish.

The root is perennial, fleshy, whitish externally, pure white within, conical at the top, cylindrical, and, unlike the tap-roots of parsnips, is abruptly branched below. When bruised, it emits a volatile oil of strong, pungent odor and hot, biting taste. If eaten before this oil evaporates, it "is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally, it is rubefacient. Its chief use is as a condiment to promote appetite and invigorate digestion; but it is also occasionally employed in medicine." (U. S. Dispensatory.) As a table relish, the consumption of horse-radish is increasing, and greater attention is being paid to its cultivation than formerly. Under the old methods, profitable returns were often secured, but under the new, profits are generally highly satisfactory where enemies are not very troublesome. The season of fresh-grated horse-radish runs almost parallel to that of oysters, with which the root is most frequently eaten in this country. Ungrated roots are, however, kept in cold storage for summer use, since roots dug at that season have an unpleasant taste.

Horse-radish will do well upon almost any soil except the lightest sand and the heaviest clay, but a deep loam of medium texture and moderate richness, well supplied with humus and moisture, will produce roots of the best quality and the largest size. In dry soils the roots will be small, woody and deficient in pungency; in wet soils, small, succulent, strong-tasting. Drainage is essential, and so is a fairly open subsoil. Hard subsoil induces excessive branching of the root. Applications of nitrogenous manures should be rather light, commercial fertilizers rich in potash being given the preference. Rolfs recommends a mixture containing 10 per cent potash, 7 per cent phosphoric acid, 4 per cent nitrogen, 600 pounds drilled in to the acre. A heavier application broadcast and deeply plowed under, it is thought, would give better results, since the shaft of the root is less likely to become unduly branched when the food is below instead of above and around it, especially when the sets are placed horizontally. A weeder should be used after the harrow periodically until the plants are an inch or so tall. Thorough preparation of the soil is essential.

Since horse-radish rarely produces seeds, cuttings are made from the roots not less than ¼ inch thick and 4 to 5 inches long (Fig. 1849). To facilitate planting the large end up, the upper end is cut off square and the lower oblique. If set small end up, no growth may result. In horizontal planting this special cutting is unnecessary. Root-crowns are sometimes used, but since these develop a large number of roots too small for profitable grating, they are employed only for increasing stock.

1849. Root-cuttings of horse-radish. (×⅓)

The land having been prepared, shallow furrows are laid off 30 inches apart and 2 to 5 inches deep, according to the method of planting. Sets are planted horizontally, vertically, and at all intervening angles, the large ends being made to point in one direction to facilitate cultivation and digging. The angle is a matter of choice, good returns being secured in each. The usual distance between sets is about 12 inches. Cultivation is given after every rain, or once in ten days, until the leaves shade the ground.

Double-cropping is common in horse-radish growing, early cabbage, turnip beets and other quick-maturing plants being used. The sets are dibbled in two to four weeks after the first crop, vertically, 18 inches asunder, between the rows of cabbage, which are not less than 2 feet apart. One management answers for both crops until the first is removed, when, after one cultivation, the horse-radish usually takes full possession. Deep burying of the sets at the time the first crop is planted is also practised, the object, as in the first case, being to prevent the appearance of the former until the latter is almost mature.

Horse-radish makes its best growth in the cool autumn, steadily improves after September, and, not being injured by frost if undug, is usually left until late before harvesting with plow or spade. Storage in pits is best, since the roots lose less of their crispness, pungency and good appearance than if stored in cellars. In trimming for storage, the lateral roots are saved and buried for next season's planting. Exposure to air, sun and frost robs the roots of their good qualities and injures their vitality.

The insect enemies of this plant are those that attack other members of the cabbage family, the harlequin bug being the most dreaded. Remedies are the same as for other pests of this group of plants. Only two diseases have been reported, and these are seldom troublesome.

In the neighborhood of cities, especially where oysters are cheap, this crop is generally profitable, the usual retail price being 10 cents a pint, freshly grated, but without vinegar. This quantity weighs a scant half-pound. The cost of growing an acre is about as follows:

Cuttings, 10,000, at $2	$20 00
Fertilizer, 1,000 pounds	17 50
Cultivation, six times	6 00
Rent of land	5 00
Plowing, wear of tools, and so on	3 50
Setting roots, at 30 cents a 1,000	3 00
Total	$55 00

A marketable crop varies from 3,000 to 6,000 pounds, which may sometimes be sold as high as 5 cents a pound for first-class roots, and 2½ cents for second grade. Usually, however, prices seldom rise above 4 cents and 2 cents for the two grades. Under good cultivation, the proportion of No. 1 to No. 2 root is about 1 to 1 by weight. Lower prices may rule in well-supplied markets, and higher in poorly furnished, and when sold in small lots to retail graters, even 7 cents may be obtained. See *Radicula*.

M. G. KAINS.

HORTÉNSIA: *Hydrangea.*

HORTICULTURE (*hortus* a garden, originally an inclosure; *colere*, to care for or to cultivate). Horticulture is the growing of flowers, fruits and vegetables, and of plants for ornament and fancy. Incident to the growing of the plants are all the questions of plant-breeding, variation of plants under domestication, the bearings and applications of many biological and physical sciences, and the manufacture of many products. Primarily, horticulture is an art, but it is intimately connected with science at every point. From agriculture it has no definite boundary. It is, in fact, a department of agriculture, as forestry is; for agriculture, in its largest meaning, is the business of raising products from the land. It is customary, however, to limit the word agriculture to the growing of grains, forage, bread-stuffs, textiles, and the like, and to the raising of animals. In this restricted application it is practically coördinate, in a classificatory sense, with forestry and horticulture. The nursery business, as understood in North America, is considered to lie within the field of horticulture.

Etymologically, agriculture is the tending or cultivation of the fields (*ager*, field). Horticulture apparently was concerned with the area within the inclosure. Equivalent to horticulture in etymology is *gardening* (Anglo-Saxon *gyrdan*, to inclose, to which the verb *to gird* is allied). By custom, however, *garden* and *gardening* denote more restricted areas and operations than are implied in the term horticulture. The word *paradise* is connected with the idea of an inclosure and a garden or park. Early gardening books of the cyclopedia type are sometimes known as *paradisæ*. Parkinson's famous "Paradisus," or account of "a garden of all sorts of pleasant flowers," was published in England in 1629.

The only demarcation between horticulture and agriculture is the line of custom. Sweet potatoes are usually considered to be a horticultural crop in North

America, particularly in the northern states, but round or Irish potatoes are usually classed as an agricultural crop. Nor is there a definite division between horticulture and botany. The science of plants is botany; yet some of the most significant problems relating to plants—their response to the needs of man—have been resigned by the botanist to the horticulturist. Horticulture is a composite of botanical and agricultural subjects.

But horticulture is more than all this. It is a means of expressing the art-sense. Plant-forms and plant-colors are as expressive as the canvas work of the painter. In some respects they are more expressive, since they are things themselves, with individuality and life, not the suggestions of things. The painter's work excels in its power to suggest, and in its condensed portrayal of expression. But the essentials of a good landscape painting often can be presented in an artificially-made landscape. This effort to plant what the artist paints is modern. It is strictly not horticulture, although horticulture is contributory to the results, as paint-making is contributory to painting. Landscape-making is fundamentally a fine art. In this work it is treated under *Landscape Gardening*.

Horticulture divides itself into four somewhat coördinate branches, each branch comprising not only the raising of the crops but also such home or plantation manufacture as goes with the handling and the marketing of the materials (Annals Hort. 1891, 125–130):

Pomology, or fruit-growing;
Olericulture, or vegetable-gardening;
Floriculture, or the raising of ornamental plants for their individual uses or for their products;
Landscape horticulture, or the growing of plants for their use in the landscape (or in landscape gardening).

In the world at large, floriculture is the most important as measured by the number of persons interested, and by the number of species of plants that are grown (see *Floriculture*). In North America, pomology is the most important in commercial supremacy. North America is one of the great fruit-growing countries of the world (see *Fruit-Growing*). The growing of vegetables has been the last of these divisions to organize itself in the New World and to reach a commanding position (see *Vegetable-Gardening*). Landscape horticulture and landscape-gardening appeal to a constantly enlarging constituency with the growth of culture and of leisure and the deepening of the home life (see *Landscape Gardening*).

The occupation.

Strictly speaking, there are few horticulturists. The details are too many to allow any one person to cover the entire range. It is only those who look for principles who survey the whole field. Practitioners must confine themselves to rather close bounds. Consider that no less than 25,000 species of plants are in cultivation, each having its own requirements. Consider the great number of species which are actually on sale as registered in this Cyclopedia. The most important species vary immensely, the named and recorded forms often running into the thousands; and each of these forms has particular merits and often particular requirements. Consider that the requirements are likely to be different in any two places, and that the plants are profoundly modified by changes in conditions or in treatment. Consider the insect pests and fungous diseases and the many other kinds of hindrance that confront the cultivator. Consider, also, the vagaries of markets, which are ruled by questions of fancy more than by questions of necessity. There is probably no art in which the separate details are so many as in horticulture.

There is considerable diversity in the definition of the word "gardener." As understood by the gardening fraternity, it is described as follows by Patrick O'Mara: "In this country [North America] the man who grows vegetables for a livelihood is called a gardener, a market-gardener, and, in some sections, a trucker and a truck-farmer. We also have the florist, which embraces the man and woman who keep a flower-store, as well as those to whom the title properly belongs, viz., the persons who are cultivators of flowers. We have also the nurseryman, a calling separate and distinct from these, and yet the three must be combined in one individual to make a qualified gardener, or what is generally known as the 'private' gardener. Occasionally the so-called 'private' gardener is known as a 'manager' or 'superintendent,' but it may well be questioned if he gains honor thereby. When he leaves the place where the title was assumed or thrust upon him, it very frequently is left behind, but he still remains a gardener. It also tends to create an artificial distinction between many who are equals, and many in and out of the ranks believe it should be discouraged. Gardeners who have charge of public parks, cemeteries and botanic gardens, it has always been admitted, may with perfect propriety assume the name of superintendent, but the fact remains that no man who loves his craft need be ashamed to be known professionally by the 'grand old name of gardener.' . . .

"However, as there may be some danger of a man's true position in gardening not being defined in that word, I would suggest that the word professional be used to qualify it. In the eyes of some outside the ranks, it might have weight, and it would certainly be a proper distinction from the amateur gardener, the trucker, the nurseryman and the commercial florist. It would be well also to have all gardeners' societies known as an association of professional gardeners. It might operate to classify properly those who are entitled by education, experience and natural ability to bear the title from those who, lacking all these, are yet bold enough to call themselves gardeners and to become candidates for positions which they are unable to fill with credit to themselves, with justice to their prospective employers or with a proper regard for the responsibilities they are so willing to assume. That class would be bolder than I imagine them to be if they would, under such circumstances, assume the title of professional gardener, and the well-merited ridicule which would inevitably follow the discovery of their false pretenses would be a salutary check upon others. To have a claim upon the title, a man should be able to grow flowers, fruits and vegetables both outdoors and under glass, care for trees and shrubs, lawns and roads, in short attend to every detail connected with his calling. If in addition he knows how to attend to the details of gentlemen's farming, his services should be all the more valuable. He could then assume entire charge of a place where both farming and gardening are done, and we would, if more men were capable of this, be spared the pain of seeing one or both suffer either from incompetence or want of coöperation between the gardener and farmer."

Proceeding to a discussion of the gardener's work, O'Mara continues, in his address "The Professional Gardener's Mission in Horticulture" before the Lenox (Massachusetts) Horticultural Society in 1897, as follows: "It is to that class, then, that we must look for developments of an upward tendency and they will be held responsible for any retrogression in ornamental horticulture, for they are before all others the recognized exponents of the art. It is their mission to improve, and the general opinion is that there is room for improvement, more especially in indoor horticulture. The overwhelming tendency during the past ten to fifteen years has been to make the so-called 'private place' nothing more nor less than a cut-flower establishment and a hospital for the decorative plants which are used in the dwelling-house and for outside decoration in summer; so pronounced has this become that the only difference between the commercial establishment of today and the average private greenhouse is one of size and architecture. The latter instead of being maintained, as it should be, purely to gratify esthetic tastes, is devoted to an utilitarian purpose mainly. The product is counted and reckoned at so many dollars and cents. The most the average owner sees of them is the daily or semi-weekly cut which is sent to the house. This is not as it should be, and while it is not the gardener's fault, and may not be within his power to control, yet by well-timed suggestion and persistence, he should be able to effect a gradual and much-to-be-desired change.

1850. Early picture of an American plant. Monardes (1571).

"The greenhouses should be a place of recreation for the owners, who should be induced to visit them daily, to look forward with pleasure to that visit, and the best way to accomplish this is to induce them to get a good collection of plants. A house of roses, carnations, violets or chrysanthemums has not the attraction of a varied collection, a collection, too, that embraces in their season gloxinias, tuberous begonias, cinerarias, cyclamens, caladiums, ixias, sparaxis, primulas, and other seasonable pot-plants, both flowering and ornamental foliage. It is freely admitted that variety is the soul of gardening and not less so in small than in large places. The individual preferences of the proprietor or gardener should therefore in some measure be rendered subservient to the amount of pleasure which visitors are sure to obtain from a variety of plants. I am well aware that in many places the proprietor's residence is of short duration and very often during the summer months only, so that it is difficult, nay, well nigh impossible, for the gardener to influence him in the right direction; but if all earnestly try, some are sure to succeed, and the example once set, it will soon become general."

Of horticulture there are two general types,—that associated immediately with the home life, and that undertaken primarily for the gaining of a livelihood. The former is amateur horticulture. Those things are grown that appeal to the personal tastes: they are grown for oneself. The latter is commercial horticulture. Those things are grown that the market demands: they are grown for others. In all countries, commercial horticulture is a relatively late development. General agriculture is usually the primary means of earning a living from the soil. For the most part, horticulture comes only with the demand for the luxuries and refinements of life; it does not deal with what we call the staple food-stuffs.

It is not the purpose of this sketch to trace the general history of horticulture. If one desires such outlines, he should consult the Bohn edition of Pliny's "Natural History;" Loudon's "Encyclopædia of Gardening;" G. W. Johnson's "History of English Gardening;" Amherst's "History of Gardening in England;" Sieveking's "Gardens, Ancient and Modern;" Jäger's "Gartenkunst und Gärten, sonst und jetzt;" Hüttig's "Geschichte des Gartenbaues;" the historical chapters of André's "L'Art des Jardins." Mangin's "Histoire des Jardins Anciens et Modernes." For the histories of cultivated plants, see DeCandolle's "Origin of Cultivated Plants;" Hehn & Stallybrass' "Wanderings of Plants and Animals from their first Home;" Pickering's "Chronological History of Plants."

Early American history.

In North America there was little commercial horticulture before the opening of the nineteenth century. There were excellent home gardens more than a century ago, in which many exotic plants were growing; yet, in proportion to the whole population, these gardens were isolated. The status of any modern time is accurately reflected in its writings. It may be well, therefore, to bring in review the leading early horticultural writings of this country. Few studies have been made of our horticultural history. The best is the introductory sketch, by Robert Manning, in the "History of the Massachusetts Horticultural Society," 1880. For its field, Slade's "Evolution of Horticulture in New England," 1895, is interesting. In a still narrower field, Boardman's "Agricultural Bibliography of Maine" is critical and invaluable. The chapter on "American Horticulture," by Alfred Henderson, in Depew's "One Hundred Years of American Commerce," 1895, presents the commercial side of the subject. Another fragment of the history is presented in the writer's "Sketch of the Evolution of our Native Fruits," 1898. Histories from several points of view are presented in the "Florists' Exchange" for March 30, 1895; and the writer has incorporated parts of his own contribution to that history in the sketch that follows. One may find valuable historical material in the reports of societies devoted to horticulture and agriculture; and the files of the early journals must not be overlooked. Local histories are important. All these sources have not yet been carefully explored.

The history of the subject needs to be written from the economic side, as one part in the industrial history of North America, but this has not yet been attempted. The best that may be done here is to trace some of the events from the side of the literature.

The earliest writings on American plants were by physicians and naturalists who desired to exploit the wonders of the newly discovered hemisphere. The earliest separate writing is probably that of Nicolo Monardes on the products of the New World, which was published in Seville in parts, from 1565 to 1571. The completed treatise was translated into Italian, Latin, English and French. An English edition of 1577 was entitled, "Joyfull Newes out of the newe founde worlde, wherein is declared the rare and singular vertues of diverse and sundrie Hearbes, Trees, Oyles, Plantes, and Stones. . . . Also the portrature of the saied hearbes. . . . Englished by J. Frampton." Monardes is now remembered to us in the genus Monarda, one of the mint tribes. He wrote of the medicinal and poisonous plants of the West Indies, and gave pictures, some of them fantastical. His picture of tobacco is not greatly inaccurate, however; and it has the distinction of being probably the first picture extant of the plant, if not of any American plant. This picture is here reproduced (Fig. 1850) exact size, to show the style of illustration of three and one-third centuries ago. Jacques Cornutus is generally supposed to have been the first writer on American plants. His work, "Canadensium Plantarum . . . Historia," appeared in 1635, and it also had pictures.

One of the earliest writers on the general products and conditions of the northern country was John Josselyn, who, in 1672, published a book entitled "New England's Rarities discovered in Birds, Beasts, Fishes, Serpents, and Plants of that Country," and in 1674 a second volume, "An Account of Two Voyages to New England, made during the years 1638, 1663." The "Rarities" gives specific accounts of many plants, together with pictures of a few of them, as for example, the pitcher plant. He mentions the plants which had become naturalized from Europe. There is also a list "Of such Garden Herbs (amongst us) as do thrive there, and of such as do not." This list, perhaps the earliest record of the kind, is here transcribed:

Cabbidge growes there exceeding well.
Lettice.
Sorrel.
Parsley.
Marygold.
French Mallowes.
Chervel.
Burnet.
Winter Savory.
Summer Savory.
Time.
Sage.
Carrats.
Parsnips of a prodigious size.
Red Beetes.
Radishes.
Turnips.
Purslain.
Wheat.
Rye.
Barley, which commonly degenerates into Oats.
Oats.
Pease of all sorts, and the best in the World; I never heard of, nor did see in eight Years time, one Worm eaten Pea.
Garden Beans.
Naked Oats, there called Silpee, an excellent grain used insteed of Oat Meal, they dry it in an Oven, or in a Pan upon the fire, then beat it small in a Morter.
Spear Mint.
Rew, will hardly grow.
Fetherfew prospereth exceedingly.
Southern Wood, is no Plant for this Country. Nor
Rosemary. Nor
Bayes.
White Satten groweth pretty well, so doth
Lavender Cotton. But
Lavender is not for the climate.
Penny Royal.
Smalledge.
Ground Ivy, or Ale Hoof.
Gilly Flowers will continue two Years.
Fennel must be taken up, and kept in a warm Cellar all Winter.
Houseleek prospereth notably.
Holly hocks.
Enula Campana, in two Years time the Roots rot.
Comferie, with white Flowers.
Coriander, and
Dill, and
Annis thrive exceedingly, but Annis Seed, as also the Seed of Fennel, seldom comes to maturity; the Seed of Annis is commonly eaten with a fry.
Clary never lasts but one Summer, the Roots rot with the Frost.
Sparagus thrives exceedingly, so does
Garden Sorrel, and
Sweet Bryer, or Eglantine.
Bloodwort but sorrily, but
Patience, and
English Roses, very pleasantly.
Celandine, by the West Country men called Kenning Wort, grows but slowly.
Muschata, as well as in England.
Dittander, or Pepper Wort, flourisheth notably, and so doth
Tansie.
Musk Mellons are better than our English, and
Cucumbers.
